M. Scelle Montdezert gives the history of no cases treated by salt, although he alludes to many in which the agent was successfully employed. Under these circumstances the matter came into the hands of M. Piorry, who was one of the committee appointed by the Academy to report upon the memoir, and his cases are the only ones known to us. From these researches it will be seen that the chloride of sodium cures intermittent fever, like the sulphate of quinine, by acting upon the spleen and diminishing its volume, and this sometimes in less than a minute; and in this connexion it may be of interest to say a few words in regard to the views of M. Piorry concerning the spleen in intermittent fever, and his method of diagnosing the disease.

He holds that in all paroxysmal fevers the spleen is enlarged; that the anatomical lesion is the cause, the fever only the symptom; that wherever the spleen has a greater length (measuring in a line extending from the middle of the axilla to the anterior superior spinous process of the ileum), than from 31 to 33 lines, intermittent fever exists. Believing thus, the symptoms for him are zero, while the state of the spleen stands at the other end of the scale, and is everything, percussion (pleximetric) of course being the *experimentum crucis*.

We cannot resist the temptation of here paying a tribute to the skill with which M. Piorry employs percussion in making a diagnosis. With him *auscultation* is but an infant when compared with its full-grown brother *percussion*. By its aid he interrogates the abdominal viscera as frequently as the thoracic, and with no less success, for he has brought it to an almost incredible degree of perfection. With his plate of ivory and his flattened fingers ends he diagnoses almost everything—tumours of the abdomen, abscesses everywhere, aneurism, &c. All acknowledge the delicacy and accuracy of his test, while the looker-on is lost in admiration, and wonders whether all his senses are not really concentrated in the ends of his fingers, which by constant drumming have at length become the very reverse of tapering.

Wishing, then, to experiment with salt, a few cases of intermittent fever (old staggers), contracted in Algiers were selected as subjects. Behold, then, Piorry at the bedside. The patient asserts that he contracted the fever and ague several years since in Africa; that he has frequently been cured; but that the disease has constantly reappeared at the end of fifteen days or one month at farthest. The type of the fever is tertian. The spleen is percussed and found to be abnormally dull throughout its whole extent; the entire splenic region is sensitive upon percussion, particularly over the dullest points; and each blow is accompanied by marked contortions of the countenance. This sensibility extends but little beyond the region of dulness, which last occupies an extent of fifty-three lines, measuring in the direction indicated above. To this patient a drachm of salicine is administered without producing any change in the dimensions of the spleen. A few minutes subsequently, half an ounce of salt mixed with a cup of soup is given, and upon carefully percussing the splenic region at the end of four minutes, this organ is found diminished one inch, from above downwards. The next day the spleen is found to be of the same size, but upon the administration of a second dose of salt, it suddenly contracts and measures nearly three-quarters of an inch less than yesterday. The resonance throughout the entire organ has increased while the sensibility has diminished. The succeeding day, the attack of fever is very slight, and upon giving a third dose, the disease does not return; and when seen six weeks subsequently, the patient is still free from his African enemy. Thus we see that a diminution of twenty-four lines in the length of the spleen was the result of the medicament, the fever being cured more effectually than ever before—i.e., the patient had remained free from all relapse for the space of six weeks; one month having previously been the longest period of immunity.

We have the notes of seven cases of well-marked inter-

mittent fever, in all of which the administration of the chloride of sodium was followed by rapid decrease in the volume of the spleen and cure of the febrile symptoms. We also have the record of three cases in which salt was unsuccessfully used; in one of these, the sulphate of quinine effected a cure; in a second, it too failed; while in the third, it was not tried. These were all well-marked cases of intermittent fever, such as would pass muster in any of our own malarious districts.

Let it be remembered that most of the fever and ague met with in the Parisian hospitals, is of long standing, and imported from the malarious districts of Algiers, which generate a form of the disease even worse than that found amid the marshes on the banks of the famed Maumee; that these cases have been treated again and again, have been cured now by the sulphate of quinine, now by arsenic, but only to reappear upon the slightest exposure or imprudence; in short, to recur as only the shakes can recur.

We witnessed many of the experiments of M. Piorry, and in the great majority of them, the fever yielded to salt quite as readily as to the salts of quinia. And as to the theory of M. Piorry, the spleen diminished under the use of the remedy, *pari passu*, with the febrile symptoms, in every case where the disease was cured, proving that this organ really shows the influence of remedies over this class of fevers—that it is, as it were, a febro-barometer—for the diminution of the spleen is a constant phenomenon accompanying the cure of the disease, whatever be the curative agent employed.

M. Piorry's method of administering the chloride of sodium is, to give half an ounce in a cup of thin soup during the apyrexia and fasting. It usually agrees with the stomach perfectly well, but in some few cases we have seen it excite vomiting and diarrhoea.

Three doses commonly suffice to effect a cure, the first two to be taken on succeeding days, and the third after an interval of one day. Should the spleen be undiminished in volume by the first dose, we may be sure that the remedy will not cure the disease; and the same is true of all the antiperiodics. Excepting in rare cases, the diminution of the spleen occurs immediately upon the administration of the remedy (salt or sulph. quinine), and may frequently be detected within one minute, after which the organ remains stationary until a second dose of the medicament be administered.

Is the chloride of sodium as efficient an antiperiodic as the sulphate of quinine? Are the cures effected by the one as permanent as those effected by the other? The first question can only be answered by those possessing a larger field of observation than the writer. May we not hope for a solution from those of our profession who observe the disease too largely either for comfort or pleasure? In regard to the permanency of the cures, we apprehend there is not much difference, be the medication what it may; for relapses are only too common after the greatest care and most patient attention.

Should the discovery prove as useful and applicable as it promises, the benefit accruing from it will be immense. If it be capable of taking the place of the sulphate of quinine in the majority, or even in one half the cases of intermittent fever, therapeutics will be largely the gainer—*Amer. Jour. of Med. Sci.*

## CASE OF DISTENDED GALL-BLADDER.

By W. BUDD, M.D., Physician to the Bristol Infirmary.

A MAN, aged 35, of spare habit, was admitted into the Bristol Infirmary in a state of imminent danger. He had been ill three weeks with pain and urgent vomiting, and had the appearance of a person dying from internal strangulation. The main symptom was an enormous swelling of the abdomen, occupying its entire upper half. Just above and to the right of the navel, over a space as large as the palm of the hand or more, the swelling was much more prominent than elsewhere. Bulging abruptly out at this point from the surface of the general enlargement, it had just the look of a large abscess, which had reached the stage of "pointing." Over the same place fluctuation could be distinctly felt, and from its marked and superficial character, it was plain that the walls of the sac, whatever the sac might be, were very thin. The extreme tenderness of the part, however, prevented the examination that would have been necessary to trace its exact outline.

The history was that of a surfeit on oysters and beer, followed by pain and urgent vomiting. The bowels were obstructed for three days, but at length yielded to medicine: the vomiting, however, continued. He had never had jaundice, or suffered from gall-stones, but had been a confirmed drunkard. Much difficulty was experienced in determining the nature of the abdominal tumour. By some it was considered to be abscess, by others an hydatid cyst, in which inflammation had been recently set up, but both these opinions seemed to the author to be untenable; first, because there had been no previous jaundice; and secondly, because the ejecta had all the characteristics of bile. The author states that under this doubtful state of diagnosis his treatment was chiefly directed to the mitigation of symptoms. This was followed by some subsidence of the vomiting, but in the evening he threw up a large quantity of green bile, which was followed by immediate relief.

On the following day all pain had ceased; the abdominal tumour had entirely disappeared, and the liver had retreated within its normal limits. Since this time his recovery was uninterrupted. The following comments on the case are given in the words of the author:—"Many important reflections occur to the mind, in dwelling on this remarkable case. In the first place, the obscurity was entirely removed by the event; for it is scarcely necessary to observe that after the crisis which occurred on the night of admission, there could be no doubt, notwithstanding the absence of jaundice, and the frequent presence of bile in the ejecta, that the abdominal enlargement was caused by retention of bile, through some obstruction in the course of the common gall-duct; and that the sac was, after all, a distended gall-bladder. One of the important points of the case consists, in fact, in showing that the concurrence of the circumstances here specified constitutes no bar to such a conclusion. It may be further added, that a little consideration suffices to show that the anomaly they seem to offer is more apparent than real. For, it is not too much to say, that this anomaly is at once explained by reference to the exactly analogous circumstances which are often observed in the case of retention of urine. In one case, as in the other, the gland continues to separate from the blood the elements of secretion, so that the system is kept free from taint. In the one case, as in the other, these elements are cast out into the natural receptacle, which provides, by its gradual distension, for the gradually increasing accumulation. In both again, the gland as well as the bladder, yields to the distending power, and makes room, in its own way, for the fluid which the bladder has no longer space to hold. The parallel does not even terminate here, but extends to the mode in which that partial relief is obtained, by which alone, in many cases rupture is averted; for there can be no reasonable doubt that the bile which occasionally appeared in the matters vomited, in the case of John Morgan, had escaped from the gall-bladder by the same mechanism as that by which small instalments of urine distil from the over-dis-

**TREATMENT OF INCONTINENCE OF URINE BY CAUTERIZATION OF THE NECK OF THE BLADDER.**—M. Demeaux narrates several cases in which this annoying malady was speedily cured by cauterizing the neck of the bladder with Lallemand's caustic bougie. The cases include both sexes. The involuntary emission of urine is frequently seen in infancy, but seldom occurs after 8 or 10 years of age, and when it does so the tendency generally disappears at puberty. Numerous measures have been recommended, such as cantharides, tinct. ferri sesquichloridi, strychnine, &c., but as all these fail, M. Demeaux's proposal is worthy of trial.—*Rev. Méd. Chir.*

tended urinary bladder in cases of retention there. The outward discharge of this bile, as proving communication between the biliary passages and the intestinal to be still extant, although obstructed, was, I need scarcely add, a fact of the first importance in regard to treatment. Very probably, too, it alone rendered the continuance of life possible for so long a period under such circumstances; for, failing the relief thus afforded, it is but too probable that the gall-bladder, tense as it was in spite of such relief, would have given way under the constantly-increasing distension. In the absence of direct evidence the nature of the obstruction itself must of course remain a matter of conjecture. Judging from the circumstances amid which it arose, on the one hand, and the persistence of a partial communication on the other, the probabilities are, that it was caused by inflammation and swelling of the lining membrane of the duodenal, and of the common gall-duct, propagated upwards from the gut. Microscopic examination of the stools might, perhaps, have thrown some light on this question, but want of time and other circumstances prevented my having recourse to it. The great length of time the obstruction lasted tells much against the notion that spasm was much, though it might have been partly, concerned in it. Many of the circumstances of the case, however, among which I may mention the characters of the urine, coupled with what we know of the pathology of this class of affections, renders it not improbable that the irritant action of an excess of acid in the upper part of the *primæ viæ* might have played an important part in the phenomena. The continued deficiency of bile in the stools, after the obstruction had given way, would admit of various interpretations. It might have possibly been owing to an early stage of cirrhosis, brought on by the patient's habits; or the secreting power of the liver as well as of the kidney might have been impaired, by the long-continued pressure to which the secreting element had so long been subjected; or lastly, some mechanical obstacle might exist to the flow of bile into the intestine." The author, in conclusion, comments upon the caution inculcated by this case with reference to surgical interference; for although a case is recorded, in which a distended gall-bladder was tapped without injury, such proceeding cannot be taken as a precedent.—*Prov. Med. and Sur. Jour.*

#### CASE OF POPLITEAL ANEURISM TREATED BY PRESSURE.

By W. K. SWETTENHAM, M.D., Surgeon 44th Regiment.

I BEG to submit the undermentioned case of popliteal aneurism, which has been successfully treated at Gibraltar Rock, under the pressure plan, affording an additional example of the triumph of art in surgery. The instruments employed were those invented by Mr. Read of Dublin, and delineated in Dr. Ferrall's paper on popliteal aneurism, in the second volume of the *Dublin Quarterly Journal*, from which plates the pelvic instrument was constructed by a blacksmith on the station, for a case of the disease which occurred in a regiment some years previously. The lower instrument, or circular compressor, was made at the same time, consisting merely of a screw-shaft through the anterior ramus of the instrument, to which was attached a covered cork pad. My patient, Henry S.—, aged 32, able-bodied seaman of H.M. ship "Phaeton," first applied, on the morning of the 10th of July, at sea, to Dr. White, surgeon of the ship. On examination, he found a pulsating tumour in the left popliteal space, then about the size of a pigeon's egg, spherical in form; pulsation strong, and evident to the eye, having a distinct soufflet audible. He was sent to Gibraltar for treatment, from the squadron, in the "Fury," with a detachment of 100, this being the only pressure attempted. He was admitted into the Naval Hospital at Gibraltar on the 12th of July (the sick of the fleet being temporarily under my charge). He is a fine, healthy-looking young man, who states that he has served in several line-of-battle ships, and always enjoyed good health; was not aware of any swelling in the left ham until the forenoon of the 9th July, but had aching pain in the

left leg for four or five nights previously, which came on gradually when in his hammock, and which he attributed to rheumatism; is positive that he received no injury, and can assign no cause for the disease, except that the ship was exercised the two days previous. On admission, a tumour was visible in the left ham, about the size of a small orange, soft to the feel, and having a strong pulsation and loud bruit audible; the circulation through the sac was controlled by pressure of the finger on the artery in the upper third of the thigh.

On the 15th of July, the instruments at hand above alluded to were attempted to be adjusted; but being found in many respects objectionable, and requiring some alterations, were not reapplied until the 21st, when both the pelvic, or upper instrument, and the lower, or circular, were put on at the same time, with the thigh kept slightly bent on the pelvis, and the leg on the thigh, resting on a pillow. The pressure was first commenced on the pubis. He was duly instructed as to the *modus operandi* of the cure, and directed that when the pain became severe he was to relax the upper, and screw on the lower instrument, which was left lax on the thigh at the upper third. During the first and following day, he was unable to bear the pressure of either instrument for a longer period than half an hour to an hour—sometimes less; and experienced considerable pain in the calf of the leg, as well as along the tibia. It was, however, remarked that he bore pain unusually long; and being an intelligent man, he controlled the circulation by the feeling of pulsation in the tumour, which he was sensible of, and which he was cautioned not to obstruct completely.

On the 22nd, he says he passed a restless night, from pain in the knee; but towards morning he relaxed the instruments, and slept; a slight turgescence of the veins around the knee being only perceptible when pressure was put on. The temperature of the limb is not much lower than the opposite; it has a flannel roller applied. The pressure throughout this day was kept up regularly and alternately with the two instruments, and at no period entirely obstructing the pulse in the tumour, or discontinuing pressure. He had each night, from the 15th, half a grain of acetate of morphia, and eight drops of tincture of digitalis, as a draught. 23rd: The tumour is sensibly harder, and a few turns of the screw of the lower instrument easily controls the circulation through it. The pressure from the pad in Scarpa's angle has irritated the integuments, and the lower instrument was moved down, and pressed on the artery in the middle third of the thigh: this enabled him to bear the instrument on a much longer time, and being without sleep, he observed the pressure having regularly and completely controlled the pulse in the tumour during this night.

In examining the limb on the morning of the 24th, I relaxed both instruments, and found the pulsation of the tumour quite ceased; nothing more than a *fremitus* perceptible. The instruments were kept on the thigh, with but slight pressure, to ensure safety, for the two successive days. The tumour felt hard, and he complained only of stiffness in the knee-joint. The temperature of the limb was somewhat less, but no œdema whatever occurred, nor was there any lividity visible during the whole period of pressure. 26th: The tumour is perfectly solid, and diminished in size; feels no inconvenience but rigidity of the limb, and his health has in no way suffered. 31st: Is walking about the ward, able to extend the limb, and place his weight on it; surface of the tumour painted with iodine; and gentle friction is relieving the rigidity.

Aug. 13th: Still in the hospital; the tumour in the ham is not larger than a Spanish filbert; has perfect good use of the leg; the pulsation of the femoral artery felt to the inferior third of the thigh, likewise in the collateral branches; is in very good health, but the heart's action has been feeble throughout; and upon minute examination of the aorta in the epigastric region, a soufflet is audible, distinct from the heart's action; from which fact it is my intention to invalid him from the service, the fleet at present lying in the Bay.—*Lancet.*

## REVIEWS AND NOTICES OF BOOKS.

**PRACTICAL OBSERVATIONS ON DISEASES OF THE LUNGS AND HEART.** By ARCHIBALD BILLING, M.D., F.R.S., Member of the Senate of the University of London, Vice-President of the Royal Medical and Chirurgical Society, &c. &c. &c. London. 1852. 8vo, pp. 138.

Dr. BILLING's name is familiar to the profession in connexion with his "Principles of Medicine," a work which has already reached a fifth edition, and has taken a place in our standard medical literature. In the volume before us he has, in a small compass, given the result of his long experience in some of the more frequent forms of disease of the heart and lungs, and at the same time he has touched upon some of the disputed points in the physiology of these organs.

The volume commences with general remarks upon the stethoscope and auscultation. The author then dwells at some length upon the mechanism of production of the normal sounds of the heart. What is termed the "valvular theory" of these sounds was first put forward by Dr. Billing, although often incorrectly attributed to M. Rouanet. "On first perusing (he observes), thirty years ago, Laennec's assertion that the second sound was caused by the auricles, I perceived that it was erroneous, as being inconsistent with the successive actions of the heart acknowledged by physiologists from the time of Haller, and fully confirmed by experiments on animals."

Dr. Billing considers that both sounds of the heart are entirely valvular. "The natural sounds of the heart (he observes) are nearly similar to each other; the first occurs with the beat (systole) of the heart, the second immediately after. They are caused by the valves, which, being membranous, each time they resist the reflux of the blood are thrown into a state of sudden tension, which produces sound." He denies that any part of the first sound is due to *bruit musculaire*. "In health there is no *bruit musculaire*, and the cause of the first sound being slightly longer than the second consists merely in the difference of the forms and attachments of the valves."

"The semilunar valves being inserted into circular rims and themselves quite free, are tightened instantaneously; the ventriculo-arterial valves, with irregular margins, and attachments to carnea columnæ, are not so instantaneous in the check, and therefore the sound is a little longer, and less sharp. An idea of this may be given by striking on the table with the tips of three fingers firmly touching each other at the points, in the form of the semilunar valves; the sound will be sharp and instantaneous; but when the fingers are allowed to separate ever so little, it is impossible to strike with them so as to produce this single sharp sound; and this illustrates the cause of prolongation of the first sound."

Dr. Billing next devotes a short space to diseases of the lungs—viz., catarrh and bronchitis, pleuritis and pneumonia, &c. He describes the auscultatory signs, and gives some useful hints respecting the treatment of each. Diseases of the heart are then considered in the same way. The following extracts from this part will give our readers some idea of the author's style; the subject discussed is palpitation:—

"There are palpitations and irregular actions of the heart depending on innervation, and not necessarily associated with change of structure, though in many instances the two co-exist; the commonest is mere palpitation, or extra-rapidity of action; the simplest cases of this occurring in persons in good health, but of an excitable nervous system, whether good or ill-tempered. This is the lowest degree, and scarcely to be denominated disease; but when persons of this temperament become even slightly deranged in health, these palpitations become a serious addition and prominent symptom, and sometimes are the most complained of by the patient, and not unfrequently distract the attention of the attendant from the real disease, whether that be hepatic, uterine, renal, intestinal, or other.

We have now to consider an opposite state of innervation. In the preceding, we have had the nervous influence in excess—too much steam; on the other hand, we find the ma-

chinery of the heart and pulse sometimes flagging from deficiency of nervous influence; in which case every now and then the muscles make a pause, causing intermission of the pulse. This intermission occurs with all states of the heart, sound and unsound; because as it depends on the nerves, we may have an intermitting pulse with a perfectly sound heart, when the system is debilitated by any cause, either of internal organic affection or disease produced by external causes or circumstances, or by some drug, such as digitalis, colchicum, green tea, &c. Intermission of the heart is no evidence whatever of disease of the organ; and many persons who have been subject to palpitation in early life, become at an advanced age liable to intermission on account of the facility with which their nervous system is exhausted; and several persons have been brought to me with supposed 'fatty' disease of the heart (a fashionable complaint just now), the organ being lazy, and which only required tonics and extra-allowance of wine to restore it to regular action; which I need not say would not have removed the fat in about a week, if that had been the cause.

I have found more persons misled by impulsion of the heart than by any other stethoscopic sign. In many cases of phthisis I have been referred to in consequence of apparent hypertrophy of the heart, which depended merely upon the increased perceptibility of the heart's action (somewhat increased in reality by the progress of the disease) from the excessive thinness of the parietes of the chest. Other patients have fits of palpitation of the heart from dyspepsia, &c., during which the impulsion is so great as to mislead the practitioner, if he have not opportunities of ascertaining that for weeks during the intervals of the attacks, the action of the heart will be perfectly normal."

The section upon diseases of the heart is followed by a short one upon aneurism of the aorta: the author attaches a good deal of importance to resiliency of the pulse as a sign of this affection. The last subject discussed is phthisis, upon which the author gives his views at greater length. Some of his remarks upon treatment we shall extract here. Is consumption curable? Dr. Billing asks. "Decidedly so, for a time (but, like gout, *naturam expellas furca, tamen usque recurret*); thus it is very seldom that there are but a dozen or two, or a hundred or two, of tubercles. If that be all, when they are expectorated the patient gets well, and remains so until after a year or two, or more, when a fresh crop forms; if these be not too numerous, the patient may recover again and again."

"One thing of which I am convinced is, that the true principle of treating consumption is to support the patient's strength to the utmost; and that though occasional complications may call for antiphlogistic treatment, *tubercular disease, by itself*, does not. I must again caution young practitioners against shutting up phthisical patients in warm rooms. I am satisfied that the want of exercise induces a languor, which makes them wear out faster than if permitted to ride or walk according to their strength in the open air. At every exacerbation of their complaint, phthisical patients say they have 'caught fresh cold'; but the same thing occurs when the experiment is tried of keeping them in rooms graduated by a thermometer. A mild climate is palliative, by permitting more free exercise in the open air; but when we look at the specimens in our museums, we may judge whether a warm climate could regenerate such lungs.

Inasmuch as we have as yet discovered no remedy for tubercle, we can only support Nature through the progress of it, as we do with strumous tumours. It is a disease which has always afforded a harvest to quacks, and to quackish regular practitioners, whether they have been knaves or fools. Some infatuated persons have thought they could cure it because they did not understand the difference between it and inflammation, and indulged in other misconceptions. Every new agent and new medicine has had its turn in disappointing the world in this *opprobrium medicorum*. Beddoes was sanguine that by inhalation of gas the disease might be modified; Darwin was sanguine as to the effect of digitalis, because it could make the pulse slower; but retarding the pulse did not retard the disease any more than the use of cod-liver oil. It is essential to the disease that the pulse is quick, but making it slower does not touch the tubercles; it is essential to the disease that the patient wastes away, but putting fat on his outside by means of cod-liver oil does not touch the tubercles, or restore the disorganized lung, though it nourishes, like

other oleaginous articles of diet, and gives false hopes to the friends of the patient, who does not live five minutes longer than if he had not taken it."

Dr. Billing's object in this publication has been, he tells us, to make it a vehicle for conveying useful practical information rather than for chronicling rare or curious cases (not, however, from any deficiency of the latter). The only fault we find with it is, its too great conciseness; for there are several parts of the subject upon which the author might have enlarged with much advantage to his readers.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, SEPTEMBER 15, 1852.

### WORKING OF THE DISPENSARY ACT.

In our last we published a letter on this subject, and in our present number we print another. It is evident that the measure is liable to most mischievous and oppressive application by those entrusted with its execution; and that if it does not admit of correction by the Commissioners or the Queen's Bench, in a revision of the acts performed under its authority, legislative interference will speedily become necessary. The Dispensary Surgeon is subjected to the control of so many masters, and affected by so many conflicting opinions and interests, that he can have little self-reliance or confidence in the assistance of those upon whom he should rely for support. The Committee say and do one thing, the Guardians another, and the Commissioners may differ from both; leaving the party responsible for the results, and obviously the most competent to judge, to carry his views into practice as best he may. Our correspondent in the last number says that "the districts are about double the size they ought to be, extending from ten to sixteen Irish miles from end to end." If this be so in any case, the fault lies with the Commissioners; for we can scarcely blame the Guardians for limiting the number of dispensaries in the union for economy sake, when they find they can do so without being questioned by those in authority over them. The truth is, that the ratepayers very naturally look upon the law as a grievance, and whenever they can do it they will limit or obstruct its operation; but this cannot be permitted, for if the Commissioners do not coerce them, some other power must interpose. But does the abuse of which our correspondent complains prevail generally? He says that "nearly the entire population beneath the class of gentlemen is attended gratuitously," and that "there is no limit to the issue of tickets, farmers of forty or sixty acres without difficulty obtaining the necessary order." Is there no remedy for so gross a misapplication of public money, and so intolerable a trespass on the Surgeon's professional services? The act provides one, but as our correspondent says, it is "a delusion and a mockery;" because, although the Committee is empowered to refuse medical relief to such persons, there is seldom a Committee to act; and moreover, if the Surgeon refuses to submit to the extortion, he "makes an enemy of the gentleman who grants the ticket." Here, then, after all the speechification, pamphleteering, and parliamentary inquiry regarding this most flagrant of the abuses of the old dispensaries, have we it quietly adopted in the new ones; and thus one of the benefits, so vaunted by the authors of the change, is scattered to the wind. How often have we heard the philanthropic political economists of the day deplore the evil of

providing medical relief for persons able to pay for it, and adduce it as one of the examples of Irish political malpractice; yet now do we find mischief perpetuated, and that not by stealth, job, or manœuvre, but openly, with the connivance of Relieving Officers, Committee men, Guardians, and Commissioners. If this be not corrected, the Legislature must interfere. The Relieving Officer alone, or some other responsible officer, must be entrusted with the duty of declaring the fitness of objects for medical relief, and must be made answerable for any misapplication of the law; while parties convicted of an unwarranted demand on the public institution, should be compelled to pay for the relief improperly obtained. In England cases have occurred in which persons not entitled by poverty obtained medical relief, and in which the value of it was recovered in the county court; why should not a similar remedy be adopted here? A few "processes" at quarter sessions against some of these claimants to the title of pauper might correct this disgraceful practice, or perhaps a remedy might be found to reach the Guardian, Committee man, or Relieving Officer by whose connivance the fraud is perpetrated. If some check be not speedily provided to arrest the progress of this evil, we shall in process of time have the principle of a graduated system of eleemosynary relief established throughout the country to the great injury of the people already too prone to accept such alms. At all events, if a rate is to be levied to pay the Doctor's bills of small farmers, shopkeepers, and tradesmen, it should be sufficient to reimburse those who are thus disabled from obtaining a livelihood by the legitimate practice of their profession. It is quite clear that if the Guardians and Committee men be authorized to compel the Dispensary Surgeon to attend their tenants and followers gratuitously, his source of income must be cut off, and the wretched pittance doled out in the shape of salary will prove utterly inadequate to his support. We do not advocate the limiting of medical relief to mere paupers, far from it, we only advocate the justice and policy of restricting it to those, who, if not so relieved, must speedily become paupers. But the fact we believe is, that no such practice as this complained of is sanctioned by law at all, and that it is only tolerated to save trouble and conciliate opponents, regardless of the consequences which such tergiversation must entail in the sequel.

### MEDICAL LIFE IN LONDON.

London, August 30, 1852.

#### THE HOSPITALS.

A CONTRAST of our hospitals now to those of the last century is highly instructive; and nowhere, perhaps, are hospitals so well managed and supported as in London. On the Continent, every one must have remarked the half-military, half-workhouse, whole government kind of institutions they appear, in Paris especially, being all supported by the State; the nurses, with their very bushy moustaches and military caps, appearing a different sort of animal from the nurses of the other sex; we are accustomed to the eternal *bouillie*, and multiform shapes in which *ptisans* are prescribed, ever reminding one of a different latitude altogether from that of London porter, blue pill, and *haustus niger*.

The contrast of our hospitals now to what they were at the time of the Plague of London is quite sufficient to account for all we read in romance writers, and even in the stern description of Defoe of that period. It was Sydenham first suggested in our London hospitals that patients attacked with the *exanthemata* were not to be broiled with heat and smothered in a dark room. One of the hospitals of

Paris has at this moment a double set of walls—a kind of brick-and-mortar quarantine; a curious relic of these old times. Inside these walls, the *religieuses*, priests, &c., we are told, were regularly imprisoned, tending the sick, and keeping off the contagion, good easy people, that they were actually creating. The Duc de Liancourt tells us in the chief hospital twenty five beds served two hundred patients: four wretched beings slept in each bed, while four others were stretched on the ground. It was a high crime and misdemeanor to get sick at all. Men and women lay huddled together. Two-thirds of those that died, it was quite well known, fell victims to the contagion generated in the wards, not the disease they came originally afflicted with. Two thousand died annually at the gate, not thought about at all. A decree of the parliament of the time is still in the Louvre, showing the mode in which contagion was sought to be "frightened" away; there is nothing like it perhaps but what one now and again reads in a Dublin paper, of a child exposed on a shovel to frighten the fairy out of it. The monkish character of all the old London hospitals—St. Thomas's, St. Bartholomew's, &c., and the cotemporary history of the time, fully corroborate the lamentable ignorance existing at this time on the subject of contagion; and just now when no two men can be brought to agree about the contagiousness of cholera, serves to indicate how obstinately men may go on in a course radically wrong, and effect legislative enactments radically nonsensical.

At the time Guy founded the hospital that gives to his name a deserved and undying fame, Cullerier tells us it was customary to huddle seven or eight patients into one bed, in wards into which the light or clear breath of heaven never upon any account whatever entered. One should be inclined to doubt if patients could live at all under the conditions; but the books of the time and the praises bestowed on Guy, swarm with such accounts. Half the patients, no matter how sick they were, slept from eight o'clock at night till one o'clock in the morning; the other half, no matter how feeble or debilitated, in the same beds from one o'clock till eight o'clock again. Everything was darksome, black, *tapissé*, with every sort of *malpropreté*; the windows all, nailed; filth never disturbed, the straw not changed for months and months; bedclothes and curtains unwashed, thick with matter from ulcers; everything, in fact, putrid and horrible. The city was "un veritable cloaque;" the king himself, tucking up his royal trousers, went to the hospitals, beseeching the people to clean their houses and the streets; the sick he noticed in large letters at every corner—"Que incontinent . . . se departent de la dite ville et forsbourg sur peine d'etre jettez en la riviere."

With this *Salvator-Rosa* dash of horrors—the secret of all our old diseases and the Plague—we can better estimate the value of our excellent London hospitals, as at present organized, founded, and organized by good and charitable men, and all supported by voluntary contributions.

We said a few words before of St. Thomas's; a few words, in a discursive way, of Guy's may now be not uninteresting. As far as the pupils are concerned, the two are almost one and the same hospital, a mere crossing of the street separating the two institutions. A kind of friendly and generous rivalry also subsists between the medical attendants, rather pleasing than otherwise. On operation-days the pupils of each hospital visit the operating theatre of the rival hospital, and the somewhat antiquated surgery of St. Thomas's and the very "fast" practice at Guy's, are openly dismissed. "I say, Armstrong," one hears ever and again, "what a d—d maff that old — is; he had the point of the knife through the interosseous." "Gentlemen, the patient is now removed; I may say this is an intense instance of osteo." "Silence, please." The Guy's men move like a field of corn. Another operation for hernia—"Beautiful! beautiful!" every one says under his breath; "Devilish

good!" when the director at last slips under a shaving of soap, like silver paper. It is some of the young men, Mr. Simon, or some one else, who is operating. A cluster go on round the wards, if with one of the old men, it is like a quaker's meeting—not a word; if at Guy's, with Bransby Cooper, it is a running fire of fun and physiology, much preferable; if with Mr. Hilton, it is good sound sense, and the oddest sort of stories; if at St. Thomas's, with Mr. South, you are initiated into everything, from Druid circles to Don Quixotte—anything but modern surgery.

The bells of St. Barnabas are not more regular at St. George's than the different men at their appointed hour at the Borough hospitals. It seems a plenary virtue of Mr. Green, and others of the very great men, however, to say or do nothing. In Paris, the continued grimace and action of Jobert Velpeau, Ricord, the gossiping soberness of Roux, contrast a little marvellously with the mild, silent equanimity of some of the older men here, who never say a word, so that the visitor to London will do well to make for the youngest man he can find out, if he wishes to see anything in a London hospital.

The division of labour at Guy's and other large London hospitals is very remarkable: everything is like clock-work. Splints are put up, the femoral tied, or prayers and testament read, without ruffling a hair. The postman goes through the wards as if it was Piccadilly or Saville-row; the apothecary, not quite smelling of Sabeian odours, brings a tourniquet, or an enema, and reads the *Times*—dividing his solicitude between all three.

Guy's, we need scarcely say, was founded in 1721, by Thomas Guy, a simple London citizen, worth several of your kings of France, walking up and down again with his kingly trousers tucked up. Guy's is, perhaps, the most striking monument of practical charity in the world, the great refuge of the sick and helpless in London. Patients are admitted according to the intention of the benevolent founder, on all but simple application; no interest or letter of recommendation, we believe, is necessary. The good old legend one ever reads over the gate in letters of iron—"Dare quam accipere," is to us always, amid the pettiness of London medical trading, a little volume of surpassing interest; not forgetting the statue of the excellent founder, and bas-relief of the good Samaritan, so quietly appropriate.

Somehow one always associates this little square and the chief wards with the name also of Sir Astley Cooper, who has done so much for Guy's; as much perhaps as your princely Carmichael for the Richmond.

Three physicians and three surgeons daily visit Guy's at one o'clock, and three assistant-physicians and three assistant-surgeons, besides apothecaries, and other assistants, give their aid in the same toilsome duties. There are 580 beds to be visited, with a vast crowd of out-patients. The good feeling and *esprit de corps* of every one at Guy's is truly wonderful. Old pupils from the country visit Guy's when they come to town as an old and valued friend. Whatever *niaiserie* and do-nothingness men feel are the besetting sins of Royal Colleges of Surgeons and Physicians, and whatever ludicrous pretensions about Apothecaries' Hall to rule the profession, at one or other of the Borough hospitals, or perhaps, Bartholomew's, all the medical men in England feel once again at home. Here are the old familiar faces, and something always new and professional. The Library of the College of Surgeons, or the Reading-room of the Medical-Chirurgical Society, or the more monastic seclusion of the College of Physicians, will, according to some universal law of reading-rooms, degenerate into mere gossiping clubs, with all their bitterness and jealousies; but there is no source of jealousy going round Guy's when a man is turned 50, and has only left his own hospital of eleven beds and a half in the country the day before yesterday, dines with one of the Guy's or Bartholomew's men to-day, prescribes for his one rich

patient a hundred and fifty miles off by electric telegraph, and dines at home before the week is out. The Library of the College of Surgeons, of course, is the great central point of all its members visiting town; taken in connexion with the magnificent and beautifully arranged collection of the Hunterian Museum, there is nothing so valuable in Europe. When one speaks in disparagement of the College itself, it is in sickness of soul at its utter inefficiency in keeping down quackery and illegal practice; its *laissez faire* mode of receiving men's money for a diploma; enrolling them members of a College that they practically make worth nothing; their reserving all their thunder and fire in the medical journals supported by them for the really well qualified man. The very deficient preliminary education they require from men entering the profession, whose business through life it is intended to be; in a word, the way everything is done in a miserable mercantile spirit, to get as many surgical fishes into the corporate net as possible. Of the College of Surgeons' Library and the Hospitals, we cannot, however, but speak in terms of the most unqualified satisfaction. Our colleges and medical schools, however, are too much dependent one on the other; the former, in England, are too eager, like good schoolmasters, to turn out so many bran-new surgeons every year at twenty guineas a piece, to give the slightest attention to the great avalanche of illegitimate practice that every day swallows up so many practitioners. Of twelve men, full of hope and life, that we remember going through the desolating ordeal of this College from one class, and they are but the exponents of thousands of others in England, we would cite the following instances of success:—

Of twelve men made surgeons when they should be at Eton or Cambridge, five "cut" the profession altogether, and are living in the "bush" in Australia; three men are homeopaths and quacks, one of them making a large fortune, with a brougham and pair, the other two also in splendid practice; a ninth, the best educated of the twelve men, thoroughly gentlemanlike in his manners, and a good surgeon, after being broken-hearted with the utter inefficiency of his London diploma, turned concert singer, and only then knew happiness; one man died all but insane, having taken the word "surgeon" off his door, as something disgraceful; the eleventh man got into the navy, but left it immediately; the twelfth man of this delectable College turned pawnbroker. Side by side with these men we could place twice twelve who have made fortunes in England, but they have all commenced as chemists prescribing over the counter, without any shadow of a diploma whatever. We have been told over and over again of members of this twenty-guinea College in the London police and labourers on the railroads; men who will talk to you to this day of Sir Charles Bell and Sir Astley with the greatest warmth. With such things meeting men in practice every day, he would be a bold man who would say Medical Reform is not loudly called for. The London hospitals, as medical schools, are without a rival in the world; but if they bear the same relation to practice in after life that the preaching and practice of self-denial and charity in our church pluralists do, the sooner we have a change the better. In Ireland, also, we scarcely require more sheets of paper called diplomas.

At Guy's, and the various hospitals, all of course is gaily and *coulour de rose*. We have known dozens of men also get into good practice, but the practice was made already by a father, or some relative. A medical journal lately very complacently tells the young chickens not to take the water too soon, but remain five years before they look for a first fee; heaps of practice lie around, however, let only the young man abjure all allegiance to Edmond Balfour and his brass wand. The fact is mournful, perhaps; we only pretend to say of our every-day experience of the men we see, that it is true. Mr. Yeatsley asks where are the police to prevent quacks lecturing with skeletons near the London Hospital?

We say the police should be in the profession itself. We have "death in the pot" and microscopical moonbeams in pickled cucumbers; but the profession itself going fast to the dogs.

Medicine in England is now half ashamed to be recognized as the same thing it was a century ago. Among the Athenians there was a law that no slave or woman should dare to study medicine; in Smyrna they associate on their coins the names of their celebrated physicians with the effigies of their gods. The members and fellows of the College at Lincoln's-Inn now deal in phlebotomy, and perfumery, and green grocery. Linacre, the founder of the College of Physicians, found medicine so distracted he changed his profession and became a clergyman; Harvey, need we say, was despised and rejected of men, and went through the purgatorial fires of London, and starved at Richmond, his doctrine of the circulation of the blood universally scouted; Cullen, and Hunter, and Jenner also, with many others, were sacrificed to the trading principle. How many Cullens and Hunters now going over to homeopathy and quackery it is painful to think. We have a cabinet of beautiful names of wards at Guy's—Lydia, Esther, and Martha; on the second floor, Charity and Dorcas; and higher, Patience and Mary—names that might be advantageously transferred to wards in Dublin hospitals. The men's wards are—Lazarus and Job, Naaman and Luke (little epics in their way, quite refreshing), Barnabas and Miriam, Samaritan, Philip, Ruth, and the great accident ward, Cornelius. Here the friends of patients at set times are met with beaming faces, bringing olive branches and mignonettes. On particular days at St. Thomas's there is quite a flower show; the pupils seem to rejoice in the general sunshine, an illicit trade in big bottles, cakes, and roast pig, is sedulously winked at; an oyster supper winds up the evening. At the London Hospital every one goes to Greenwich or Blackwall. These are the last happy hours many, alas! how many of these men ever spend! They are seduced by the blandishments of the old lady in Lincoln's-Inn-square at last, they have half finished their education. The old lady snubs them politely when she has got their money. A new curriculum is now entered on for what they call "Rhubarb Hall," and just when friends are tired of them, and a little fortune thoroughly wasted, they find the blue bottles opposite of the trading chemist quite eclipsing their little light; the College takes no further trouble of them, or what it styles its fellowship, than it does of the title of the Emperor Soultouque. In Ireland, the really valuable diploma of the College of Surgeons was recognized by act of parliament as indispensable for the attendants on infirmaries; in England, it is a pleasant and ready way to shut a man out from all civilized society, and in country parts means something equivalent to green grocer, or a shadow and a half less respectable than that important functionary.

#### THE VALUE OF UNIVERSITY DEGREES AND DIPLOMAS IN MEDICAL QUALIFICATION.

The venue in this case has been (to the great relief of us here in Dublin) changed to another locality, and we are thus enabled to discuss the abstract question with less danger of bias. The intrinsic value of University Medical Degrees as qualification to practice may be ascertained as easily by reference to their origin in Aberdeen as in our own metropolis, and so we give insertion to the following reclamation on the subject. But it is not even the value of the Degrees and Diplomas which have become the subject of discussion, but the value of the very Charters which profess to confer the right to grant them. It seems beyond a doubt that of all personages in the world, the Pope has established a right to found Universities in these countries, and not only is this so, but a noble Scottish chieftain seems to have exercised a similar power. In England, the Bishops

can "make Doctors" too, but whether they can do so in Ireland we have not learned. Perhaps Dr. Todd, who, they say, is particularly anxious to acquire the power by virtue of a mitre, will take "a law opinion" on the matter. In the meantime, we stand by QUEEN VICTORIA, notwithstanding the disregard of her royal prerogative displayed by the Board of Trinity College. We are so old-fashioned in our belief that we really do attach more value to specific modern charters of incorporation granted by HER MAJESTY, after careful scrutiny by the Law Officers of the Crown, than to the vague generalities of similar documents granted in an age all but barbarous, and by persons all but incompetent. After all, perhaps these disputes will prove of value by opening men's minds to the real question at issue, and may lead them to distinguish between shadow and substance; in fact, to consider how far caps and gowns, and hoods and surplices, stand for real knowledge and substantial requirements. Here is the pleading in the cause to which we allude:

MARISCHAL COLLEGE, ABERDEEN.

The employment of your most powerful pen to expose the abuses which have so long deprived the title of M.D. of half its dignity, must be a source of pleasure and profit to all who have a legitimate claim to that honour. To show the state of ignorance in which even the profession exists as to the rights of the different colleges (by the way, we feel sure the "British Medical Directory" will enlighten us on these points), I confess that, subsequent to graduation, I learnt the legal right of Marischal College is disputed. Although aware of a difference between that college and University and King's of the same place, I had always considered it a professor's squabble, caused by anxiety to obtain the greater number of graduates.

A pamphlet, however, bearing the modest title—"Has Marischal College, in New Aberdeen, the Power of conferring Degrees in Divinity, Law, and Medicine?" drawn up and published by a Committee of the Senatus, startled me with its copious extracts from the charters of each. It would occupy too much of your valuable space to give more than one or two extracts from this paper, which is evidently drawn up for the sole purpose of elucidating the truth. But it is only fair that those who intend to present themselves for examination at Aberdeen should be acquainted with some of the grounds on which the authorities of University and King's distinctly deny the legal right of Marischal to grant degrees in medicine.

The University of Aberdeen, founded by Pope Alexander VI., at the request of James IV. of Scotland, "for teaching theology, the canon, and the civil law, medicine and polite literature, or any other lawful faculty, in the same manner as in the Universities of Paris and Bologna," had a college endowed within its limits by Bishop Elphinstone, the Chancellor, in 1505. The title, "University and King's College, Aberdeen," was first employed in the act of the Scottish parliament (1633), when the change from popery to protestantism rendered a new charter necessary. Marischal College, founded by George, Earl Marischal, in 1593, designated a public gymnasium, was established by him to supply the deficiency of "literary and Christian education." The only allusion in the original charter to medical education occurs in the required duties of the principal, who, in addition to giving instruction in sacred literature and two of the oriental languages, to explaining the principles of geography, chronology, and astronomy, and occasionally teaching theology, had to give a short explanation of anatomy and physiology.

"The word Doctor, or Doctoratus, does not occur in the charter of foundation, nor in any of the documents confirmatory of it.

"We think we may without fear of contradiction affirm, that Marischal College is not recognized as an University, nor as possessing the powers of an University, in any charter or act of parliament, the object of which is to specify, limit, extend, or protect the privileges of the Universities of Scotland.

"We have examined the charters, acts of parliament, &c., with a sincere desire to arrive at the truth, and have presented to our readers the results of our investigation. These results must speak for themselves; and we are quite satisfied that every unbiassed judge, who has followed us in the de-

tails, must come to the conclusion at which we have arrived; viz., that the University and King's College, in virtue of the charter of foundation, charters of erection, deeds of confirmation, &c., possesses the right of conferring degrees in all the faculties—arts, divinity, laws, and medicine; while the privileges of Marischal College are confined exclusively to the Faculty of Arts, that being the only faculty which is mentioned in the charter of foundation, or in any of the other documents printed by the Royal Commissioners; and therefore that it does not possess the right of conferring degrees in divinity, laws, and medicine."

I recommend the careful perusal of the above-mentioned pamphlet to all who desire the honorary distinction of Doctor of Medicine; and feel certain that, owing to the very careful examination adopted by its professors, University and King's College, Aberdeen, will soon hold that place in the estimation of the profession which it so well merits.—*Letter of a Graduate of University and King's College, Aberdeen, in Lancet.*

[The question as to the legal power of Marischal College to grant medical degrees has now arrived at a point that demands its immediate settlement. If the college does possess the power, the managers of that institution must at once produce the evidence of its existence. Arguments and statements will now be unavailing; the production of the proof, and nothing short of the proof, will or can satisfy the profession. If the evidence be contumaciously withheld, or if it cannot be supplied, in either case the profession will decide, and promptly, that Marischal College has neither a legal nor a moral justification for granting degrees in medicine.]—*Ed. L.*

THE LONDON UNIVERSITY.

We are glad to find from the following that there is one *Alma Mater* in the three kingdoms without gray hairs or wrinkles, or tottering steps and drivelling intellect. But what has become of your young Irish sister? Has she died of a political puerperal fever in her first confinement?

The list of undergraduates who have just passed the first examination for the degree of M.B. of the University of London, exhibits certain features which illustrate in the most interesting manner the beneficial tendency of the University in promoting the general education of the members of the medical profession. The provisions wisely designed by the senate for this purpose have at length come into full operation, as far as the University itself is concerned. Those students who began their professional education prior to 1840 are exempted from the matriculation examination; and hitherto there have always been some candidates for the degrees in medicine who were in a condition to claim the benefit—if it may be considered a benefit—of that exemption.

This year presents the remarkable fact, that every candidate in medicine was already a matriculated student of the University. It may now fairly be inferred that the stock of medical students who commenced their studies before 1840, and who aspired to the London degrees, is exhausted. Another circumstance is observable. The reputation of the London University has annually attracted several practitioners possessing other diplomas to contend for the medical degrees. This year there is not one. We do not believe, however, that events have yet reached that point at which the class of gentlemen in practice before the year 1840 will cease to furnish candidates. Out of something more than 200 students who passed the matriculation examination in July last, we are informed that eighty reported themselves as intending to proceed to a degree in medicine. This fact offers a most gratifying proof of the extent to which the ambition to obtain the London medical degrees has already operated among the rising generation of medical students. It also indicates, in the most convincing manner, the future importance of the medical faculty in the University. We are glad to observe that a considerable proportion of students in medicine do not rest content with simply matriculating; an increasing number proceed to the degree of B.A. In the present list, out of twenty-one successful candidates, five are Bachelors of Arts. The operation of the regulations relating to the classical and mathematical examinations further explains a circumstance which some persons have been disposed to interpret as evidence of the declining interest in the medical section of the University of London. It has been remarked that even in the earliest years the number of candidates for the degrees in medicine was as high as the latest examinations. The reason is obvious. At the outset, professional acquirements only were demanded: the matriculation examination was not im-

perative. In process of time the proportion of candidates who could claim exemption from the matriculation examination, on the ground of having commenced their medical studies before the year 1840, has been gradually diminishing; while the regulation requiring from all subsequent candidates proof of having passed the matriculation examination, naturally kept down the number of aspirants until the rising generation of those destined for the medical profession could be educated to enable them to comply with this preliminary requirement. The present long list of medical undergraduates, and the striking fact that no less than eighty of the last batch of matriculated students have expressed their intention to take degrees in medicine, must remove all doubt that there will be a rapidly increasing addition to the graduates in medicine of the University of London. — *Lancet*.

### THE TITLE OF "EM DEE."

WHAT between the squabble of rival diploma dealers, and the tricks of travellers yearning after "medical honours," the title of "Doctor" is in jeopardy; if not all titles heretofore accepted as evidence of qualification. Now that "Army Surgeons" can be "made" by official ledgermain, and, for anything we know to the contrary, "Dispensary Doctors" too, our prospects are anything but cheering:—

I perceive that the Editors of the "British Medical Directory" have discovered that there are some—they might have truly written many—gentlemen in this kingdom, glorying in the title of M.D., whose diplomas are absolute forgeries. This disgraceful fact has been long known to many members of the profession; but, there is no remedy by which they can correct this grievous and scandalous imposture, nor can it be effected by the combined efforts of the medical press, whatever amount of zeal and ability may be employed to attain so desirable an end; nor would it be fair to impose the task upon it. But might not the legislature take the matter upon public grounds? and ought not the several colleges to take an active part in protecting their members against an abuse so detrimental to their interests? The state of our profession in the united kingdom has no parallel in Europe. Until some more effective remedy for this disgraceful state of things be adopted, I would suggest, that local boards, consisting of the senior members of the profession, be formed in each county, before whom any one about to settle in their respective districts as a practitioner, or offering himself as a candidate for any professional appointment therein, shall produce his credentials for approval; and should any doubt arise as to their validity, that a communication be addressed to the institution from which such documents may appear to have issued, a fee being paid for the performance of the duty.

There are many practitioners glorying in the title of M.D. *Lambeth*—divine doctors you used to call them. Should you not exclude from the "British Medical Directory" these high feathered birds hatched by the archbishop, as well as foreign graduates. I really do not see any difference between these two classes, and you cannot, in common fairness, recognize the one and reject the other. What would foreigners say when they find you repudiate the holders of their diplomas, and at the same time water and plant the fungous growths of the ecclesiastical establishment at Lambeth? I must confess that I am of opinion (and I am a septuagenarian) that it would be more consonant with the feelings of these anti-monopoly and free-trade times to retain in your medical list ALL *bona fide* graduates, and leave the public and the profession to appreciate them as they will. If you exclude them, we shall have a race of quacks immediately assuming titles to which they have no possible right of pretension. Besides—and this is important—I would foreign countries recognize British degrees, while we scout theirs? — *Letters in Lancet*.

### CORRESPONDENCE.

#### WORKING OF THE DISPENSARY ACT.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR, It would almost appear that our silence under the grievous oppression and injustice inflicted upon us by the Medical Charities Bill, or rather by the mode in which its provisions have been carried out by the Commissioners and Boards of Guardians, has been regarded as evidence of assent on our parts to the acts of those parties. Be assured the contrary is the fact; and how could it be otherwise?

The salaries given in this union (confessedly one of the worst administered in Ireland) are disgraceful, and were at once sanctioned by the Commissioners; not a word of remonstrance about the matter! I am even worse off than your correspondent, "A Fellow of the College." To this district two medical officers have been appointed, the district being divided as nearly equal as may be; the population in each being, in round numbers, 8000, valuation £9000, extent in statute acres 10,000, including a densely populated town district. For the duties required here, and fairly stated by your correspondent, £50 per annum the Commissioners have sanctioned as sufficient remuneration. I am frequently called upon to go miles into the country, at all hours, even the most inconvenient. Is it any wonder that we should be treated with degradation by the local poor-law authorities when the Commissioners have estimated our services at so low a standard? It is no wonder; and we are treated with contumely accordingly on every occasion. Last week the following resolution was sent me:—

"The following was this day passed in reference to the Medical Charities Act, proposed by A. Browne, J.P., and seconded by Anthony Mathews, Esqrs.:

"Resolved—That previous to the payment of the medical officers, a certificate from the committee of the district to which such medical officer is attached shall be laid before the finance committee, stating that such officer has carefully and diligently attended to the duties of his situation, and that the district committee are perfectly satisfied with his conduct; and that a copy of this resolution be forthwith forwarded to each medical officer of dispensaries situate in this union. — Carried. (Signed) CASTLEMAINE, Chairman.

Athlone, August 30, 1852." "I find only one resolution to be passed, and that is, 'to do nothing' as it is expressed in the original. The board had clearly no right to pass such an insulting resolution; but it shows the animus of the body. As the cholera will, in all probability, visit us before very long, it would be well to inquire how the fearful increase of duty consequent upon its appearance is to be met, and our truly,

A FELLOW OF THE COLLEGE ALSO.

Athlone, September 10, 1852.

We cordially assent to the assertion of our correspondent that the Board had no right to pass such an insulting resolution. There is no use in fencing with these "Guardians" any longer. Their powers must be strictly defined; and the powers of the Dispensary Committee must be secured so as to put a stop to the conflicts already commenced between the parties. Above all things, the Surgeon must be protected against both; and he shall be protected.

### THE CHEMISTS AND DRUGGISTS OF GREAT BRITAIN.

OUR extensive correspondence and personal communication with the members of the pharmaceutical body during several years, have made us acquainted with their position, requirements, habits, and general sentiments. So far as these bear upon their future prospects, a few remarks may not be out of place. The most striking characteristic of the chemists and druggists prior to the formation of the Pharmaceutical Society, was the total absence of chemical affinity for each other. Nothing but actual persecution or bodily fear could bring them together. The cause being removed, the effect ceased; and until the recurrence of a similar source of attraction in the shape of a new peril, the repulsive force prevailed. No other communications of an official character ever took place between them; and in the meetings which were held, the science of the chemist was overlooked and forgotten in the defensive struggles of the tradesman. Even between individuals there was an unaccountable reserve in reference to chemical subjects and pharmaceutical qualification. It appeared to be forgotten that knowledge—like

money—produces interest by circulation, and that knowledge is the true source of power, position, and respectability. When the permanent union of the chemists for mutual improvement and advantage was proposed, the chief obstacle to be overcome was the incompatibility of the elements to be united; and the senior members of the trade, judging from past experience, considered the project chimerical. Upon a further discussion of the proposal, it was discovered that the shyness and reserve which had hitherto prevailed, was rather habitual and superficial than constitutional; and when the ice was broken the current began to flow in the right direction, and a disposition to go with the stream was manifested. Jealousy and distrust gradually gave place to more worthy sentiments, and although some of the old leaven still remains to be rooted out, the absence of chemical affinity for each other is no longer the characteristic feature of the chemists and druggists. When the detailed plan of the society was suggested and discussed, it was received in a manner symptomatic of the disjointed and unorganized condition of those to whom it was addressed. It met with an immediate response from some whose own experience had led them to similar conclusions, who were sensible of the evils, and rejoiced to see that others concurred with them in desiring to provide a remedy. Some granted the hypothesis, but denied the practicability of the deduction. They said nothing could be done without an act of parliament, which it would be impossible to obtain, and suiting the action to the word, they withheld their coöperation. A considerable number, however, although only partially convinced, followed the example of those in whose judgment they had confidence, and lent a helping hand. Others, again, shut their eyes against facts and their ears against arguments; denied the existence of abees on one side or danger on the other, and composed their minds in an artificial security, as the ostrich buries his head in the sand, and thinks himself safe because he can see nothing. Lastly, there were the systematic opponents of change, who think it "better to bear the ills we have than fly to others that we know not of;" and the advocates of peculiar crotchets, who view every subject through their own telescope. Such were the auspices under which the Pharmaceutical Society was introduced. It may be supposed, therefore, that it was no easy matter to smooth down asperities, and adapt its constitution and regulations to the sentiments and circumstances of the parties concerned. Some advocated a high subscription to ensure respectability, others, a moderate one to avoid exclusiveness; some thought the examination should be compulsory on all members from the commencement; others desired that not only the original members, but associates and apprentices should be exempted. On other questions conflicting opinions arose, and it was not easy to adjust the balance. These difficulties were gradually overcome, in consequence of the disposition which prevailed among the majority to waive minor prejudices for the sake of attaining the great object—unity; and although it was impossible to please all, an amicable arrangement was effected by mutual concessions, and the constitution of the society settled down to its present state. Similar influences prevail to a greater or less extent in the provinces and in the metropolis. In most towns, some of the most intelligent and respected inhabitants are chemists. We continually find them filling responsible offices, such as mayor, magistrate, guardian of the poor, &c.; and also connected with sanitary committees and local institutions of a scientific and useful description. They are not usually addicted to politics, but it will be generally found in any town where a chemist enters into such matters, he holds a prominent position in the committee of his party. We have observed rather a tendency to conservative principles on general subjects, and also in reference to sweeping reforms and changes in their own business or profession. The services of chemists on juries are held in estimation; they are considered, as a class, superior in intelligence and experience to the average of tradesmen, and this is urged as the principal argument against their exemption from serving on juries. The chemist and druggist, although not a professional man, is usually recognized as a link between the trade and the profession. His avocations, if faithfully and conscientiously performed, demand the exercise of the mental faculties, and the knowledge thus acquired lays the foundation of the influence and respect which he enjoys. This is the case with the *bona fide* chemist and druggist, who has voluntarily taken the means to establish a fair reputation in his business. While, however, the merits and character of some individuals reflect credit on the class, this is in some degree neutralized by the delinquencies of others, and the mixture of the business of the chemist and druggist

with other trades is carried to such an extent in many places, that it is quite impossible to draw the line with a view to classification. In one town with which we have communicated, a majority of the chemists and druggists are ladies, an occurrence not unfrequent in other places. In most towns there are some whose business consists chiefly in counter-practice, who are engaged from morning till night in prescribing for the poor at twopence or threepence per dose. These are the parties who bring down upon the entire body the indignation of the apothecaries, and are pointed out as illustrations of the encroachments of the chemists and druggists. It is, however, admitted on all hands that those who carry on and encourage this kind of business occupy an inferior position in the trade, and that in proportion as they rise as chemists, they avoid instead of courting the responsibility of irregular medical practice. Since the establishment of the Pharmaceutical Society, a considerable improvement is observable in the general character of the business; for although chemists and druggists cannot be driven, they may be led, and a society of this description, established on a sound basis, and inculcating certain principles, exerts an influence which spreads by imperceptible degrees, and the result is manifested by the increased desire for information, the adoption of improvements in the mode of conducting business, the encouragement of education in the junior members of the trade, and the desire to assist in the measures requisite for raising the status and qualifications of its members. These effects are most observable in places where a sociable and friendly disposition prevails among the chemists, and more especially where endeavours have been used to obtain an honourable understanding with the members of the medical profession, who have in some instances given their cordial assistance by delivering lectures, attending scientific meetings, and reading papers. Where the chemists will not be induced to come together or to observe what is passing around them, no progress can be expected. They adhere to the habits of their forefathers, adopt the ostrich as their model, shut their eyes and ears against evidence, and believe themselves to be secure. In a few years they will wake from their sleep, and on taking a bird's-eye view of the pharmaceutical chemists of Great Britain, they will find themselves, like Rip Van Winkle, a generation behind their brethren. *Phar. Jour.*

## A BULLET EXPELLED FROM THE BRONCHUS AFTER FORTY DAYS.

By Dr. BENEYS.

The patient, V., aged 21, had an attack of bronchitis. One day, a pistol-bullet, which he had in his mouth, passed, during a deep inspiration made after coughing, into the larynx; it descended along the trachea, and entered the right bronchus, stopping at the root of the lung. The symptoms produced were pain in the right side of the chest, hectic, marasmus, suffocative spasmodic cough, and other marks of advanced pulmonary consumption. While in this state, he was one day stooping forward, when he coughed up the bullet with about three tablespoonfuls of pus. In about two months, health was perfectly restored. Dr. B. thinks that this case points out the propriety of trying the effect of placing the patient, who may have allowed a foreign body to pass into the air-passages, in a favourable position for its expulsion. Notwithstanding the favourable termination of the case, we must not trust too much to the resources of Nature; for this man would have inevitably died if he had not fortunately, being accidentally in a favourable position, expelled the bullet. — *Lond. Jr. of Med.*

## ON AN EFFECT OF CONGENITAL PHYMOSIS.

In a young man, aged 20, the subject of congenital phymosis, Dr. Riecke found that the expulsive power of the urethra was lost, so that the urine, instead of being ejected, simply flowed out as from a tube. The canal had become so dilated, that it was wider than the neck of the bladder, and more than a quart of urine could be poured out in a few seconds. The ejection of semen would also probably be impossible. Dr. R. remarks, as an evidence of the state of surgery in the provinces (in Prussia) that, although the nature of the disease must have been evident, yet none of the surgeons whom the patient had consulted, had proposed an operation, while all had prescribed diuretics. — *Id.*

### CURIOUS CASE OF NEUROMA PERVADING ALL THE NERVES OF THE ECONOMY.

M. HOUEL has brought before the Surgical Society of Paris a remarkable case of neuroma, affecting all the nerves of the frame. Before entering into particulars, M. Houel stated that six analogous cases have been recorded. Two of these were noted by M. Serres, in 1847; he calls them, in the "Comptes Rendus" of the Academy of Sciences, "ganglionic transformations of animal and organic life." Two other cases were reported by Schiffener and Wurtzer; and Professor Smith of Dublin has cited two examples of the kind in his excellent work on "Neuroma."

The patient, in the present instance, was admitted into the clinical hospital of the faculty, March 16, 1851, for the removal of a tumour seated in the right groin. Other tumours were found on the abdominal walls, on the neck, the arms, and in the axilla; the patient, however, was not aware of having so many tumours upon him, as they never had given him much pain. The tumour in the groin made walking uncomfortable, and became somewhat painful with changes in the weather. This was removed by M. Giralès on the 1st of April, 1851, and the wound took three months to cicatrize. The patient was readmitted some time afterwards, and died on December 17, 1851, no further operation having been attempted; owing to the great number of the tumours. No pain in the neuromatous growths was ever complained of, and great emaciation preceded the patient's death.

On an inspection of the body, all the viscera were found healthy, and neither the brain, cerebellum, nor spinal cord contained any tumours. In the cauda equina, however, there were a great number, as many as twenty being found on one single filament. Bischoff has recorded an analogous fact; and he had even found neuromatous growths on the roots of the cerebral nerves, one of the tumours on the seventh pair, before it leaves the skull, being of the size of a small strawberry. M. Houel did not find the nerves affected at their intra-cranial origin, but further on they presented numerous neuromatous growths, with the exception of the olfactory and optic nerves. There were likewise tumours on the motor oculi, and on the fourth nerve; the fifth also presented several neuromatous growths on each of its three divisions; they were especially numerous on the lingual and infra-orbital nerves. The distribution of the tumours was pretty similar on both sides; the seventh pair presented many growths along its distribution on the face, but the pneumogastric had the greatest number of them, and looked like a coral necklace. There were also many such tumours on the œsophageal, pulmonary, and cardiac plexuses, and all the spinal nerves were the seat of neuromata immediately after their leaving the spinal foramina.

M. Houel found a great many tumours on the cervical plexus, both as to the superficial and deep branches; the brachial plexus had also a great many, and upon a nerve belonging to this plexus the largest neuroma was found, it being about the size of a hen's egg. All the terminal branches on the right and left were studded, and the dorsal nerves bore numerous traces of this fibrous diathesis, as M. Houel calls it. The ribs had, in several places, been affected by the growth, and portions of their substance were found here and there absorbed. The lesion seemed to be more complete as regards the lower limbs, for the lumbosacral plexus presented on either side more neuromatous tumours than the axillary; the sciatic nerve had a great many, and looked as if hypertrophied. M. Houel drew the attention of the society to the fact that the nerves had assumed a varicose aspect; they looked longer and somewhat twisted, and it was easy, during the dissection, to unroll them, when they were seen to resume their normal direction. The great sympathetic was much enlarged, but there were no growths upon it. Some of these were, however, found on the splanchnic nerves. On a microscopic examination, M. Robin found these tumours composed principally of fibrous tissue, and noticed in them very few fibro-plastic elements.—*Lancet*.

### A TREATISE ON CATARACT;

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F.R.C.S.,

Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5s.

### THE INFLAMMATIONS OF THE EYEBALL:

Being a Treatise on all the Species and Varieties of Inflammations.

Dublin: Fannin and Co., 41, Grafton-street, or the Office of the MEDICAL PRESS, 15, Molesworth-street. London: John Churchill, Princes-street, Soho.

G. OLDHAM and Co., Pharmaceutical Chemists, and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

### THE COMPOUNDING DEPARTMENT AT G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin, London: John Churchill, 46, Princes-street, Soho.

CASE OF EXTENSIVE CANCER OF THE LIP:  
OPERATION: RECOVERY: ADVANTAGES OF  
HAINSBY'S APPARATUS: APPLIED NOW FOR  
THE FIRST TIME AFTER THE OPERATION  
FOR CANCER.

By RICHARD G. H. BUTCHER, F.R.C.S.I.,

Surgeon to Mercer's Hospital,  
Examiner on Anatomy and Physiology in the Royal College  
of Surgeons in Ireland,  
&c. &c. &c.

I SHALL first detail briefly the history and nature of the case calling for the following observations, and then allude to the special points attended to in the treatment:—Thomas Henry, a coachman, aged 43, admitted into Mercer's Hospital, under my care, August 29, 1852. He states that seven months prior to admission, "a small welt," which he had noticed in the lower lip for many years, became exceedingly painful, so that his attention was constantly directed to it. He was in the habit of feeling the part, and was often compelled to compress it forcibly to deaden the stinging pain. After a short time, a little blister formed over the tubercle; the mucous membrane was detached, and there issued a constant moisture of thin fluid from the exposed surface. The abraded part was exceedingly sensitive, so that the patient kept it constantly covered with a piece of black plaster. During the following months it increased rapidly, seizing upon and including nearly two-thirds of the lower lip, and extending a little beyond the left commissure. The entire ulcerated surface was elevated, irregular at the margins, and quite hard; it had extended on the inside of the lip, nearly as low as the point of reflection of the mucous membrane, from the lip to the maxilla, and externally on a line somewhat below this part. The tumour was uneven on the surface, elevated in some places very considerably by the deposition of new structure, and as it were dug out in others, forming small pits, from which the abundantly secreted sanious discharge constantly trickled over the chin. Again, the disorganized part was peculiarly sensitive to the lightest touch, and yielded blood

VOL. XXVIII.

readily on being handled. On the most careful examination, I could detect only one lymphatic gland, either hardened or enlarged, about the neck; situated just near the angle of the jaw, corresponding to the lower and anterior edge of the parotid on the left side. This was not much increased beyond its normal size, and the patient assured me that it had been enlarged, and had remained so after an attack of mumps which he suffered from, many years before his lip got bad.

The operation being decided on, it was performed in the following way:—Standing in front of the patient, an incision was commenced at the prolabium, a quarter of an inch to the right side of the tumour, and the knife carried rapidly downwards and inwards to the middle line of the chin, and to its lowest margin. The tumour, though not involving the upper lip at the left commissure, incorporated itself with the lower for half an inch beyond this point. To remove effectually this portion, the second incision was complicated in the following way:—The knife was carried from about two lines above the commissure horizontally, but with a slight inclination downwards, through the left cheek, for three-quarters of an inch, and then directed beneath the projecting nodule of the tumour, downwards and inwards, to nearly the same extent: thus a small triangle was formed, the apex externally and the base, including the projecting part of the tumour, marked by a line let fall from the commissure. The knife from this point was carried very obliquely downwards to the lowest part of the mesial line of the chin to meet the first incision; the obliquity of this line was such that, when drawn up at the point from which it commenced, the base of the small triangle, to form a commissure, the remaining portion of its extent was as long as the first incision which had been executed more vertically. Owing to the transverse width of the part to be removed at the prolabium, it was essential that the lateral incisions should be carried as far down as specified; and still further to facilitate the approximation of the cut edges, it was imperative to detach freely, for a considerable extent, the lateral flaps from their attachments to the maxilla. These points being attended to, the

parts yielded to traction forwards, and the divided surfaces were readily retained *in situ* by one point of the interrupted and three of the twisted suture.

The needles which I used in this case were remarkable for their length and slender proportions, being rounded in the shaft, with a long tapering triangular point; while at the other end was a small head well adapted for the finger of the surgeon, so as to take any amount of pressure required for the transfixion of the parts. The first needle was introduced near the inferior angle of the wound, and a few turns of thick stay-silk well waxed passed round its extremities in the figure-of-eight. The second needle was introduced a little higher up, and the silk made to describe the same figure as in the first instance. The third stitch was of the interrupted suture, and made at the base of the small triangle already described: thus completing the left commissure. The third needle was introduced about three-quarters of an inch external to the commissure, and carried through the prolabium of the opposite flap to about the same distance from its cut edge. When the ligature was turned round the extremities of this needle, the apposition of the parts was perfect. There were two particulars carried out here not to be lost sight of—first, the extreme fineness and length of the needles (four inches) rendered their application most easy, for when one flap was struck the opposite could be pierced at any point with the greatest facility and precision—a circumstance not readily achieved in so widely gaping a wound with a short instrument; secondly, the extent of parts embraced by each suture was far wider than surgeons usually direct.

The foregoing case required a good deal of consideration before deciding on the exact operative interference most likely to be productive of benefit. The question was: How to remove so large a portion of the lip and afterwards unite the cut edges without performing a chloplastic operation, which so frequently fails, and which may reasonably be ascribed to the ascending course which the blood must take in the flap. But I was emboldened in the measure I adopted by the cases of complicated hare-lip recently published by Professor Fergusson and others, where the amount of parts, both by original deformity and increased by former unsuccessful and faulty operations, was very great; yet by the adaptation of mechanical contrivance to the intentions of the surgeon, cure was brought about most satisfactorily.

On the completion of the operation after the method which I have described, though every precaution feasible was put in practice to relieve the dragging on the needles and the strangulation of the included parts, I could not but feel apprehensive for the result—indeed beforehand, I had estimated pretty accurately how the case would stand, but was encouraged by the anticipation of a great auxiliary in the appliance of Hainsby's apparatus. So sensible was I of the advantages to be expected from this instrument, I immediately sent to London for it, but being disappointed in its arrival, I even deferred operating for some days until I could get one constructed, which was most efficiently done by Mr. Read of Parliament-street. Immediately after the operation, I applied this instrument, and was not disappointed in my expectations. By it the cheeks were pressed forward, so as to take all strain off of the needles. The only difference in its appliance in the present instance, and that, as represented by Mr. Fergusson in hare-lip, was, that the pads at the extremities of the spring lay a little lower, and were prevented from changing their position by a band of tape passed beneath the chin from one to the other.

The needles were withdrawn in fifty-six hours after the operation, and the entire wound healed by first intention—a result which I mainly attribute to the spring apparatus employed. Its use was persisted in for some days after the healing of the wound, to support the recently united parts, and now, though only a fortnight has elapsed since the operation, it is astonishing what little deformity exists.

The original of the spring used in the present instance was brought before the notice of the profession by Professor Fergusson in December, 1850, and its history published in

the *Medical Times*. He gives the case of a child who had been operated on for hare-lip on two occasions—once by the late Mr. Liston, a sufficient guarantee that everything was done that could be for curing the deformity; but from some cause which cannot be explained, union did not take place, and the affection still remained. Whatever was the cause, no benefit accrued to the little girl from either operation. The father of the child, a very ingenious person, reasoning upon the failure of the operations on his child's lip, thought that if some instrument could be applied which might keep the edges of the wound closer together, success would follow. He then invented the instrument which now goes by his name—"Hainsby's apparatus." It consists of a spring which encircles the head from behind, and the two ends, furnished each with a pad, rests upon the cheeks, which are thereby supported in the position given to them. All dragging or strain upon the sutures is thus prevented, and pressure upon the lip, whether from the bones behind or otherwise, is guarded against. Professor Fergusson operated on this case in the ordinary manner; he applied the apparatus, and desired it to be kept on; the result proved most satisfactory, for although on the two previous occasions failure had occurred, union was now complete in every point. Professor Fergusson concludes by saying—"I am of opinion that the cure in this instance was owing, in some measure, to the ingenuity of the patient's father, and I would recommend this case to your consideration; for there are instances of hare-lip in which a surgeon will not like to operate, in consequence of the great amount of tension which will be exerted upon the edges of the wound, which will almost with certainty burst open again."

An instrument very similar to this was recommended more than a century ago (1721). (See 'Verduc's Traité des Opérations de Chirurgie,' p. 218). The direction in this book is to place the spring upon the head with the ends resting upon the cheeks; but the instrument was objected to by several eminent surgeons, when it fell into disrepute. All the objections appear to have been merely theoretical. La Charrière considered that by means of a circle of steel which surrounded the head, and by graduated compresses which he placed upon the cheeks, success would be unavoidable. For the purpose of replacing his bandage, as modified since in various ways by Quesnay, Henkel, Koenig, Strickelberger, and Eckhold, Enaux and Valentin devised those which bear their name. The supporting spring of La Charrière approximates most closely of all to Hainsby's apparatus.

Mr. Quain, in commenting on an interesting case of complicated hare-lip, which he has published in the *Medical Times and Gazette* for July, 1852, states:—"Heretofore I myself, before I had seen Verduc's proposition, applied to more than one surgeons' instrument-maker to construct a spring, with a view to another difficult case; but they did not succeed in making a useful instrument."

There are two very excellent cases of hare-lip, with protrusion of the central part of the alveolar process of the upper jaw, detailed in the *Edinburgh Medical and Surgical Journal* for July, 1830, by Mr. Dewar, and in which he used a steel spring very analogous to the one about which I have been writing. I shall quote from the periodical referred to, the reasoning which led to such an invention:—"The chief obstacle in all such cases to the healing of the wound arises from the strain which is thrown upon the pins from the natural tendency which the cheeks have to retract, more especially on any motion of the mouth, as in eating, speaking, crying, &c."

Irritation and pain are thus produced, and the healing process is greatly interrupted. "In this instance (continues Mr. Dewar, speaking of the case which he had first operated upon, "the disposition to retraction was very considerable. This I endeavoured ineffectually to obviate by compresses and strips of adhesive plaster. Louis's bandage was likewise tried, but with no better effect—a contrivance which I have in every instance found equally troublesome and inefficient. It occurred to me that as a very slight degree of pressure on the cheek on each side

near to the corner of the mouth relaxes the upper lip, a narrow piece of steel having a spring might be so adapted as effectually to answer my purpose. I had accordingly a spring made, nearly resembling a pair of sugar-tongs, and so padded as to press on the cheek near the mouth. It was kept in its place by a narrow tape tied over the chin, and by three tapes which were fastened, one behind, and one on each side to a piece of leather placed on the crown of the head. This simple contrivance answered every purpose admirably. I could relax the lip by it to any degree I wished, and it could be worn without the smallest inconvenience. The strain was thus taken off the pins, and the process of healing advanced in the most favourable manner. One pin was withdrawn on the fourth, and the other on the fifth day. The spring was worn for a few days longer. On the ninth day the boy returned home so much changed in his appearance that it was scarcely possible to recognize him."

The second case given by Mr. Dewar goes still farther to confirm the benefit derived from the use of the instrument which he had invented.

There can be no doubt, however, that Hainsby's apparatus is far superior to all others, for in its adjustment no pressure whatever is exerted over the cicatrix; and I must repeat again, in the embarrassing case which I have used it, the vast superiority of this instrument was borne out, and my most sanguine expectations fully realized.

The microscopic examination of the part taken away in the case which I have given was conducted with great care, and exceedingly satisfactory in the result; for whilst the true carcinomatous nature of the product was clearly established pervading its entire structure, yet so largely removed was it—so far wide of induration and of the confines of the malignant and ulcerated margin were the incisions carried, that on the closest investigation of the cut surfaces no trace of the characteristic cancer-cells could be discovered. I repeat the term *characteristic cancer-cells*, for I am fully convinced of their identity and distinct existence, and that the practised eye can readily detect them. This I have given demonstrative exposition of in a paper which I recently published, "On the Cancerous Degeneration of Warty Excrescences, and their Treatment." (See DUBLIN MEDICAL PRESS for March 31, 1852; see also a paper, published a few years before, entitled "Observations on Cancer and Fungus Hematodes, with Practical Deductions," in DUBLIN MEDICAL PRESS for April, 1847.) The same conclusion is arrived at by the laboured and extensive researches of Lebert, the greatest living authority on the subject. (See "Traité Pratique des Malades Cancreuses et des Affections Curables Confondues avec le Cancer, 1851.")

## RECOVERY AFTER TAKING TWO OUNCES OF ARSENIC.

By T. BRYANT, M.R.C.S.

W. C—, aged 30, single, a butcher, and a notorious drunkard, after having received some act of apparent unkindness from an aunt from whom he had "expectations," was induced to poison himself; and on the evening of July 11th, at half-past nine p.m., I was called to see him. On my arrival I found him quite drunk, could not gain any information from the friends present, and only elicited from him that he had taken about three grains of arsenic a quarter of an hour previously. As there were no symptoms of poisoning present, I returned home and gave him, immediately, an emetic of a scruple of ipecacuanha with one grain and a half of tartarized antimony. On my visit to him at half-past eleven p.m., I learnt, from a friend who was absent when I first called, that he had certainly taken *at least two tablespoonfuls of arsenic*. The emetic had acted immediately, in some measure had sobered him, and had brought up a quantity of dark-brown flaky fluid, which, on analysis, contained abundant arsenic. The man was very drowsy; skin moist; pupils natural; complained of pain on pressure over the pit of the stomach; tongue foul, but not injected; bowels purged once of a very fluid, fetid

stool; pulse 100, full and strong. After hearing the true history of the case, and as there were no symptoms of vomiting, I applied the stomach-pump, injecting barley-water (the only thing at hand) till it returned almost clear. The fluid withdrawn was more opaque, contained some brown curdy material and some arsenic, but not more than ten grains. Not feeling satisfied with this result, I ordered one scruple of the sulphate of zinc every two hours until I saw him at half-past eight a.m. the following morning. I then found that he had taken four doses of the zinc, had vomited considerably after each dose, but not continually; the fluid rejected was clear, with brown curdy flakes suspended in it (containing arsenic), and on pouring off the supernatant fluid, the arsenic collected was about sufficient to cover a shilling. The man was bathed in sweat, experienced slight pain in the abdomen, increased on pressure, but at times very severe; there was but little dryness of the throat; tongue foul and slightly injected; bowels purged three times; the stools loose and of a dark colour; pulse 100, full, but weak; and the patient expressed himself as feeling "tolerably well." The hydrated oxide of iron was given in doses of two ounces every two hours, and a dose of castor oil exhibited. Nine p.m.: Nausea, but no vomiting since eleven a.m.; still slight abdominal pain; tongue foul, but very slightly injected; bowels have been open three times with pain; motions very offensive, of a dark colour, and one looked bloody; pulse 100, full, and of more power.

July 13th, twelve at noon: Passed a good night; has still pain over the abdomen, increased on pressure; tongue the same; bowels have acted twice, but the stools were thrown away; skin moist; no perceptible dryness or redness of the throat; pulse 96, full, and of good power; indeed, the man says he is "nearly well." Continue with medicine. 14th: Altogether improved; pain in abdomen less; skin moist; tongue cleaner and less injected; no nausea; bowels open twice, and motions loose, very offensive, and dark-coloured; pulse the same. Ordered spirit of nitrous ether, two drachms, tincture of henbane, one drachm and a half, water, six ounces; take one-fourth three times a day. 15th: Still improving; no tenderness of the abdomen; tongue cleaner; bowels have not been opened; pulse 96, and natural. Castor oil, one ounce at bed-time; repeat mixture. 16th: Bowels opened four times, and motions contained scybala and blood; there is no pain in the abdomen, not even on severe pressure; tongue foul, but not injected; skin cool; pulse natural. Repeat oil. 17th: Bowels opened twice, stools depositing a white powder, and contained blood; otherwise much improved. 18th: Stools natural, but loose. 21st: Has continued daily to improve; motions healthy and solid; and indeed may be considered well.

*Remarks.*—The questions which naturally arise in the mind of any one on the perusal of the above case, would be, first,—Did the patient take *arsenic*? and secondly, What *quantity* did he really take? Now, in answer to these natural queries, I must add, that a friend of the man had a few days previously given him a packet containing about *four ounces of arsenic*, for the purpose of destroying vermin; that this packet had been placed upon a certain shelf in the stable, and that the friend had seen it there unopened on the morning of the day of the attempted suicide. On the discovery of the attempt, this same paper containing the arsenic was found at the feet of the patient, he having dropped it on hearing some one enter his room, with only about *one tablespoonful* in it. This was immediately taken by the party who discovered it to a neighbouring chemist, who, unfortunately, after mixing it in water, and not knowing what it was, or its history, threw it away on some stones before his shop.

Now, here seems a tolerably clear account that the packet contained originally about *four ounces*; none had been used, as the patient afterwards informed me; that little had fallen in the room, as none had been noticed; and the small remainder leaves a deficit of between two or three ounces; and added to this, there is the firm assertion of the friend who had been with him, and gave him

originally the poison, that the quantity at least taken was two tablespoonfuls; and the man himself says that he took all that was in the packet originally, with the exception of what was found afterwards. The quantity which was left was specified to me by the chemist and the man who took it to him, on several different occasions, as certainly not more than one tablespoonful.

Not feeling satisfied with this account, I thought some mistake must have been made with respect to the strength of the powder taken. I therefore had the powder which the chemist had thrown away upon the flag-stones before his shop collected, and through the kindness of Dr. Odling, of Guy's Hospital, who analysed it for me, learnt that it contained 95 per cent. of arsenious acid, the remainder sand, which most probably was added by the scraping of the stones during the collection of the powder. Being, then, obliged to recognize the fact that at least two ounces of arsenious acid had been swallowed, the grand difficulty remains, to account for the mildness of the symptoms which a large dose of such an irritant poison would naturally be expected to occasion. Such a result I find quite unable to accomplish, and only suggest the question whether the man, from his habit of habitual drunkenness, could so have thickened, and therefore rendered less sensitive, the lining membrane of his stomach, and thus have given more time for the means which were employed to rid that organ of its poisonous contents? Still this will not account for the absence of some symptoms which would have been expected, nor for the mildness of all those present; and I can only assign this case, as we are obliged to many others of different characters, to that class which we call anomalous. — *Lancet*.

#### REMARKS ON PHTHISIS.

By Dr. C. A. WUNDERLICH, Tübingen.

THE influence of climate on the development of phthisis is a subject on which much has been written, but regarding which little has been satisfactorily demonstrated. Bennoiston de Chateaufort has calculated that of one thousand soldiers dying in the north of France, eighty-five were tuberculous; while of an equal number in the central parts and the south, seventy-three and eighty-two were thus affected. In Marseilles, one-fourth of the population is carried off by phthisis. It is common in the West Indian islands, in Madeira, in Rio Janeiro, in New Zealand, in Nice, Florence, Naples (where, according to Journé, three deaths in every seven result from phthisis), in Malta, Spain, Portugal, Calcutta, and Madras. Hence no climate appears to afford an exemption from this malady. Wunderlich seems to incline to the belief that there is an antagonism between intermittent fever and phthisis; and hence that marsh-lands do, to a certain degree, afford a protection against this disease.

The following are the local processes in the respiratory organs which may give rise to tubercular deposits:—Frequent attacks of acute bronchial catarrh seem to predispose towards phthisis, or at all events to hasten the eruption of its symptoms; so also do epidemic catarrh and pertussis; while on the other hand, chronic bronchial catarrhs seem to keep off pulmonary tuberculosis. Pulmonary congestion is very favourable to the development of tubercle, especially when it frequently recurs and affects the upper lobes. Hæmorrhage may give rise to the formation of tubercle in a secondary manner, by the retention of coagula. Pneumonia is a very frequent cause of tuberculosis, the remains of the non-absorbed pneumonic infiltration being readily metamorphosed into tubercular matter. Emphysema, on the other hand, has a tendency to exclude tuberculosis in the lungs, or at all events to check its extension. Pleuritis with adhesions predisposes to tuberculosis, the metamorphosis commencing in the plastic exudation, and from thence extending to the lung. Compression of the lung, to a certain degree, but not altogether, excludes the development of tubercle.

The forms of tuberculosis described by Wunderlich are—1, miliary granulations; 2, crude tubercles, or tubercular nodules; 3, tuberculous infiltration; 4, tuberculous exuda-

tion in the smaller bronchial tubes. The further metamorphoses of pulmonary tubercle, whether occurring as granulations, nodules, or infiltration, are—

1. *Softening*.—This sometimes commences at the centre, sometimes at some other point, and sometimes at several points at once. The mass which was previously firm and dry, and of an almost chalky white, or very slightly pale yellow tint, begins to change to a deeper yellow, and to become soft and pulpy, till it is finally converted into a fluid containing fragments of solid tubercle, and which on a microscopic examination is found to present the elements of tubercle and a few granular corpuscles (pus-corpuscles). Thus the tubercle is converted into an abscess, sometimes only at particular spots, as in infiltration, but sometimes over its whole extent.

Simultaneously with this softening process, there is generally a further extension of the tubercular deposit in the surrounding part; and as this additional tubercular matter also softens and becomes dissolved, the fluid contents unite with those in the first abscess, and the abscess thus enlarged finally opens (most commonly) into a bronchus, but occasionally (when the disease has been very widely extended) into the pleura, and thus discharges its contents. In this way abscesses become converted into open caverns. The tuberculous cavity varies in appearance, according as this process has been gradual or rapid. In the former case, the tubercular matter at the spot is usually completely fused, and the cavity, which can then thoroughly empty itself, has smooth and tolerably regular walls. The surrounding pulmonary tissue presents a bluish tint, is lax or callous (callöse), exhibits no cellular structure, and is strewed over with isolated tubercles. If, on the other hand, the progress of the abscess has been rapid, and it has opened very rapidly, we seldom find that the whole of the tubercular mass is dissolved. The cavity is then generally irregular, opening in various directions, and containing undissolved, jagged masses of tubercle. The adjacent tissue is in a state of infiltration. Many of these cavities sometimes communicate, and we may find a whole lung perforated with them. It is seldom that a large tuberculous cavity has a simple form; even when its walls are smooth, it is usually sinuous and presents compartments, partly because it is made up of the union of several cavities, and partly because some portions of tissue not thoroughly destroyed, run across or project into the cavity in the form of rafters, ledges, cords, and bridges. These are generally composed of an obliterated bloodvessel and some atrophied and compressed lung-substance, which in this state have resisted further destruction. It is rarely that any blood passes through such a vessel; and it is only when the disintegrating process has gone on very rapidly, that the walls of open vessels are destroyed, and that blood can in this manner escape. The contents of an abscess, previously to its opening, are usually yellow, greasy, and sometimes a little reddish. After an opening has ensued, but before the cavern has perfectly emptied itself, the contents sometimes present an external similarity to pus, or they may be more diluted and mixed with blood, and be either of a dirty red, a brown, a gray, or even a blackish tinge. In a cavern of this kind we not unfrequently find free and detached, but not perfectly destroyed, portions of lung. When the contents are completely discharged, the walls of the cavern remain the seat of an ichoro-purulent secretion, and are usually invested with a greasy pseudo-membrane; these walls may become the seat of gangrene.

If an abscess breaks into the pleural cavity, its fluid contents are effused into the pleural sac, unless impeded by the presence of strong adhesions; and as there is usually a communication between the cavern and a bronchial tube, air enters with each inspiratory movement into the pleural sac. Hence there is developed a severe inflammation of the pleura with a plastic, purulent, and often ichorous exudation; and we have bulging of the side of the chest, and compression of the lung, in consequence of the entrance of the air. Perforation of the pleura is, however, comparatively rare, because the firmest adhesions usually occur at

the spot where the tuberculous deposits make their way to the pleura.

2. *Atrophy* may occur among the miliary granulations, converting them into hard, very small, bluish-gray, or black nodules, which are incapable of any further development, and which finally gradually disappear. Whether the larger tubercular deposits can undergo a similar metamorphosis is problematical.

Various pathological peculiarities may be referred to the resorption and obsolescence of tubercle. Bonet regards the change which tubercles undergo into an oval or elliptic form, as the commencement of resorption. Fournet explains the transformation of the lungs at their apices into a black and often shrivelled mass, which is sometimes hard, and intersected by cellular and fibrous cords, and is covered by thickened and wrinkled pleura—a change of no rare occurrence, as any one with much experience in post-mortem examinations can testify—as representing the remains or cicatrices of old tubercles which have been resorbed in their crude state. In examining the bodies of persons who have died from other diseases (once in a case of cancer of the stomach, and on another occasion in an old drunkard, who died from pulmonary infarctus), I have sometimes found distinct chalky concretions in spots which have undergone this change, which seem to me to strengthen the view that these puckering and shrivellings may depend on old resorbed tubercles; but whether in other cases they may not originate in a different manner, as, for instance, from obliteration of the terminal portions of the bronchial tubes, from shrivelled pneumonic infiltration, or even from insidious atelectasis, is a point which I cannot decide.

3. *Cretification* is the ordinary mode in which crude tubercle and tuberculous infiltration are rendered innocuous to the organism. Cretification occurs in much the same manner as the atheromatous and chalky degeneration of plastic exudations. The conditions necessary for cretification are, doubtless, poverty of the blood, deficiency of the vital powers, and little motion of the surrounding parts; and it appears to begin to occur when softening commences. When the tubercle has become half-softened, the process stops, and there is a deposition of a preponderating quantity of salts, some of which are soluble, as the phosphate, hydrochlorate, and sulphate of soda, while others are insoluble, as the phosphate and carbonate of lime, and an abundance of crystals of cholesterol. The mass gradually dries, and there is left a chalky residue, which at first is triturable and sandy, but finally is studded with sharp spicula of the hardness of bone, and which neither exerts any disturbing influence on the adjacent lung substance, nor on the organism in general. It is very probable that even this fragment is at length disintegrated and disappears. This fortunate mode of termination is, however, often frustrated by the circumstances, that while some of the tubercular deposits which are favourably situated for this process are healing by cretification, the disease is advancing in other parts of the lungs.

4. In some very rare cases, the tubercle becomes *encysted* by a tough wall formed by the reaction that is established in the adjacent tissue. The tubercle is either in a state of crudity or is calcified.

5. *The cicatrization of caverns* can only occur when their contents are thoroughly discharged. The walls acquire firmness and toughness, and are invested either with a mucus-membrane-like coating, or with a partially ossified callus. One or more bronchial tubes open into the cavity. A cavern of this nature may remain for a long time without undergoing any apparent change, and may during this period secrete pus, either scantily or copiously; or its aperture may close, while the investing membrane gradually approximates to a serous coat, the contents become more aqueous, and the cavern itself becomes converted into a serous cyst; or finally, the cavern may gradually diminish till it at length disappears, and there remains in its place nothing but a cartilaginous, fibrous, or cellular cicatrix. All these modes of termination are comparatively rare, and only occur when the tubercles are few and scattered, and when the tuberculous dyscrasia has become extinct.—*Brit. and For. Med. Chir. Rev.*

## TREATMENT OF DENTAL CARIES—DESTRUCTION OF THE PULP BY ARSENIC.

By ROBERT ARTHUR, D.D.S.

THE dental pulp is endowed with a high degree of sensibility; when, from any cause it becomes inflamed, this natural sensibility is exalted to such a degree as to render the slightest touch of any foreign substance a cause of the most excruciating pain. This has rendered it exceedingly desirable that some means should be used first to destroy its vitality, and thus remove this extreme sensibility before attempting to cut it out. Arsenic has been found most effectual for this purpose, and at the present time is used to the exclusion of every other substance known generally to the profession. It has been strongly contended, however, that arsenic produces results more or less injurious in every case in which it is used, and it is regarded by some as always advisable to remove the pulp with instruments, regardless of the pain inflicted, rather than to use arsenic for the purpose of destroying the vitality of the pulp. This is the question which now divides the opinions of those who practise this operation.

It is not denied that the immediate effects of arsenic, applied for this purpose, are extremely satisfactory, but it is stated that the final good result of the operation is endangered by its use. The manner in which this occurs has never been clearly stated to my knowledge—certainly not in any publication which has come within my reach. But from what I can gather from various sources, it seems to be the impression that particles of arsenic are absorbed at once, and carried to the peridental membrane, producing irreparable injury to those important parts; or that after the lapse of some time, they, in some way, reach this membrane, and thus cause their injurious results. Now, I have stated, I have seen no account of the manner in which arsenic used for this purpose is supposed to be likely to produce injurious results. It has been stated by practitioners of high standing, it is true, that in their practice, it had not proved satisfactory, but had been more or less injurious. But what is their experience, when unsustained by argument, to me, when it conflicts with my own experience? and what is the value of their opinion in this regard, stated to be based simply upon their own experience, without further rational evidence, to the profession at large, when it comes into conflict with the experience of many others of equally high standing with themselves? It is not at this time sufficient to say, that in any one's opinion, a certain course is not a good course to be pursued. Let us therefore examine this question rationally on its own merits.

It has been vaguely stated, from time to time, as we have already intimated, that arsenic applied for the purpose of destroying the vitality of the pulp, would sooner or later bring about the destruction of the tooth so treated—1st, by being absorbed and carried through the root, and so attack the peridental membrane; 2nd, by passing laterally through the parietes of the roots; and 3rd, by remaining after the pulp is removed, and in course of time finding its way to the investing membrane. These are all the reasons I have ever heard of to account for the alleged injurious results of arsenic applied for this purpose. Let us examine these statements consecutively, for it is important that we should come to a right understanding of this matter.

1st. Can arsenic be absorbed, and by this means reach the investing membrane through the agency of the pulp? Arsenic, we are told by high authority (See "Liebig's Agricultural Chemistry, chap. xiv., on Poisons, Contagions, Miasms"), is not absorbed when brought into contact with living tissues. It combines with the surface of the organ to which it may be applied, destroys its vitality, and of course the power of absorption, which is a vital function. Where the quantity of arsenic applied is so small that every atom enters into combination with a corresponding number of atoms of the living tissue, if the organs have vigour enough, it is thrown off with the tissue which has been destroyed by its action. If there is an excess of

arsenic, it may reach the vital portion of the tissue below the surface, by imbibition or capillary attraction. If this authority is of any value—and even if it is not, the known action of arsenious acid upon the living tissues is sufficient to bring any reasoning mind to a similar conclusion—it must be plain that arsenic cannot reach the investing membrane of the root by absorption. It may, however, if it be applied in excess, and allowed to remain sufficiently long, gradually penetrate so far by passing through the destroyed portion in the way indicated to the vital portion, and so on till it has passed through the root. But although it must be granted, that injurious effects may occur in this way, it can easily be shown that arsenic, applied in the usual manner for destroying the vitality of the pulp, is not allowed to remain long enough to produce the effects indicated. It is generally allowed to remain twenty-four hours only. That this is not sufficiently long to enable it to make its way through the fang by way of the canal, is abundantly proved by this fact: a small portion only of the pulp, on the removal of the arsenic applied, will be found deprived of vitality; it is probable that the vitality of the body of the pulp will be destroyed, whilst the portion in the fang will be found to retain all its vitality, and to display an increased degree of sensibility. Now, this must be regarded as incontestible evidence, that the arsenic applied has not passed through the root, because its invariable effect is to destroy entirely the vitality of any portion of living tissue with which it comes into contact. It may be said, that the fact that the part alluded to retains its vitality is no evidence that some of the arsenic has not reached it, but only that it has not had time to effect its destruction; but this objection is shown to have no weight, because these parts retain their sensibility for many days, and even weeks, as all who have practised this operation must have found.

If the views and facts here presented be correct, it is clear to me that no injury can reasonably be supposed to follow the use of arsenic in the ordinary way for this purpose by absorption, and that when allowed to remain the usual time, no bad effects can follow. I should be glad to be shown it, if I am wrong in the position I have taken. I am sincerely in the search of truth, and am not anxious to establish any of my own opinions, unless they are founded upon this basis.

2nd. Do the particles of the arsenic applied, pass laterally through the parietes of the fang? 3rd. Do particles of arsenic remain after the pulp is removed, and ultimately reach the investing membrane, and thus, after a lapse of time, give rise to injurious consequences? These queries may be answered together.

The only way in which this is possible, after the pulp is carefully and entirely removed, will be by passing through the bony substance itself by capillary attraction. That this is possible when it is remembered that the dental bone is porous, and the arsenious acid is in a minute state of division, as it is when rubbed up with creosote, which, I believe, is capable of dissolving it, cannot be denied. But that it does not occur, is sufficiently evident from a little careful observation, and a little careful consideration of the phenomena which would present themselves if this did occur. The arsenious acid is generally applied in the same manner, dissolved in creosote, generally in the same quantity, and allowed to remain the same length of time. Making due allowance for the difference in density of the teeth of different individuals, we must look for some degree of uniformity in the results of arsenic used in this way. It would take a certain length of time for the arsenic to pass through the root, and we cannot suppose the difference of density usually found to exist in the teeth of different persons would make any very great difference in this respect. The time required to allow the arsenic to pass by this means through the bone, reasoning from the analogous case of the same substance applied to the bone of a living tooth near the pulp, could not be very long. A month, we should think, would be ample time; yet after many years have elapsed, we observe no consequence of the kind. And it must be remembered, that if arsenic found its way

through the root in this way, that its peculiar effect upon the investing membrane would with certainty display itself, and would with certainty result in the destruction of such parts of the investing membrane which it touched. I find it impossible, then, in this view of the case, not to conclude that none of the arsenic, after it is applied in the usual way, is left behind after the pulp has been removed and the pulp cavity and canal in the root washed out, or if any should remain, it is so inconsiderable as to do no harm.

I think I have shown that we have no reasonable ground to suppose from the nature of arsenic, and the manner in which it affects living tissues, that it can exert any injurious influence when applied for the purpose here indicated. I am anxious that this point should be established; for unless we can use arsenic, or some agent effectual for the purpose accomplished by it, our usefulness in this way will be extremely limited. The removal of the pulp, unless it is first deprived of vitality, is, in all cases, a painful operation; in most cases excruciatingly so. It is a painful operation to remove the pulp from the incisor and canine teeth, but it can be done with great rapidity, and although the pang of pain produced is, in most cases, exceedingly severe, it is so soon past, that many persons can be induced to bear it. But when the pulp is to be removed from the contracted fangs of the molar teeth, in which it is often exceedingly difficult to find even the openings of the fangs, the operation is so excruciatingly painful, that I am sure not one patient in fifty, who have passed through my hands, would be willing to submit to it. I have already endeavoured to show why it is important that the pulp should be effectually removed.

I am aware that gentlemen have declared that the pain attendant upon the operation is inconsiderable; but this is inconceivable, I must confess, to me, unless it is performed by some method with which I am unacquainted.

I have thus far been endeavouring to show that arsenious acid used in the manner in which it is usually and generally employed in the profession at the present day, cannot reasonably be expected to do the injury which has been attributed to its agency. It must be remembered that many, if not most, of those gentlemen who have opposed its use, have been extremely cautious how they have applied it, using a very small quantity (the twentieth part of a grain), and allowing it to remain a very short time (from twelve to twenty-four hours). This last point is strongly insisted upon, as also the importance of avoiding a second application to the same tooth.

Now, I am prepared to go further still, and to declare my belief from careful observation of the effects produced by it in my hands, that it may not only be applied more than once, but be allowed to remain much longer than this, not only without injury, but with great advantage. It is true that I do not use it in the form of arsenious acid, and this may make an important difference. Of this I will say more in the proper place.

Before proceeding further, I beg leave to offer in proof of these assertions, and the above reasoning, a record of some of the cases which have passed through my hands in the course of the past six years. I have not kept a record of all my cases. Those which I now present have not been selected. In almost every case here cited, the arsenious acid has been applied more than once, in some cases as often as five or six times. Since January, 1846, the time at which I began to record these cases, I find marked down the treatment of 77 teeth in this way. Of these, 19 were incisor, or canine teeth; 31 were bicuspidæ; 20 were first and second molar teeth; 7 were dentes sapientiæ. Of the incisor and canine teeth, 18 were of the upper, and 1 of the lower jaw; of the 31 bicuspid teeth, 22 were of the upper, and 9 of the lower jaw; of the 20 first and second molar teeth, 14 were of the upper, and 6 of the lower jaw; of the dentes sapientiæ, all were lower teeth.

Of these cases, I have, from time to time, covering several years, seen twenty-six. I have not been obliged to extract one of these. In one only, which has come under my observation, has alveolar abscess occurred, and this by no means an aggravated case. It formed in about

two years after the operation was performed. The tooth treated was an inferior dens sapientiæ, and an unfavourable case, because, from a variety of causes, it was impossible to perform the operation thoroughly. Another tooth, filled for the same lady at the same time, a second inferior molar, was in a perfectly healthy condition, presenting no trace of inflammation at the time I had an opportunity of examining the other one.

Of these cases I have seen six which had been treated in this manner, some considerably over two years, and all over eighteen months; these were in a perfectly healthy condition, no trace of peridental inflammation being apparent. In some of these twenty-six cases, seen several months after the operation, there had been occasional slight attacks of inflammation of the peridental membrane, evinced by more or less tenderness to pressure, but which always passed away without giving rise to serious consequences. I have not felt obliged, as I have stated, to extract a single tooth I have treated in this way, during the five years I have been in practice in Washington. I have treated more cases than I have recorded, and the patients are where I should be sure to hear from them, if trouble occurred. That not many of them have passed into the hands of other practitioners, I may safely conclude, because most of them still send their friends to me when they desire the services of a dentist.

It will be observed, from this statement, that I have seen, from time to time, one-third of the cases of this kind which have come under my treatment. Out of these, but one case can be said to have failed, and this was evidently traceable to an imperfect operation. But even this cannot be regarded as a failure, for many such cases of abscess occur, which are completely cured by the removal of the irritating cause; probably in this instance some portions of pulp remaining in the smaller parts of the canals of the roots, and they frequently heal spontaneously.

What I principally desire to establish, by the recorded cases offered here, is, that the bad effects attributed to the action of arsenic applied for the purpose of destroying vitality of the pulp, do not in reality follow its use. For if any portion of the arsenic applied were to reach the external membrane, which it could only do by passing laterally through the parietes of the root—for all ingress through the root must be prevented by the filling—it would certainly and surely and speedily produce effects which would make the extraction of the tooth necessary. The same would be the result if any portion, however small, were allowed to remain in the canal above the filling; its effects would, indeed, be more quickly displayed.

I know that such records of general results as I have presented here, are not very highly valued in the profession; for men, the most honest in their intentions, are so apt to see things in a favourable light when they wish to do so. After theories are formed, we are so apt, almost unconsciously, to make facts bend so as to establish their truth, and facts stated as having been seen in this light, are justly regarded with many grains of allowance. But the cases I have presented, if they are true, and I affirm that no bias or prejudice could lead me to make, knowingly, a single misstatement or exaggeration, even if they do not convince the sceptical of the permanent utility of the operation (for it may, with truth, be said that time enough has not yet elapsed to test its full value), it will at least make good the point for which I am now contending, and will show that the operation advised is productive of results sufficiently desirable to warrant its practice. In the course of the treatment of the cases of which I have here presented a mere meagre outline of general results, I have learned many instructive lessons. I have, in many of these cases, recorded a great deal that was interesting and useful to me at the time, and which has led me to conclusions which I hope I may be able to state in such a manner that they will be useful to others. I know well, now, that if I could have had the same directions to guide me in the course of my own practice, in this way, I should have been saved much trouble and my patients much pain.

—*Amer. Jour. of Dental Science.*

## A CASE OF SUB-LUXATION OF THE CERVICAL VERTEBRÆ.

By W. BRYAN, M.D., of Beverly, New Jersey, U.S.

I was called, October 22, 1851, in haste to see a daughter of A. S—, a girl about eight years of age, whom I found sitting on a table, her face turned towards the left shoulder, the head immoveably fixed, making fruitless efforts to bring it to a normal position, every effort producing excruciating pain. Upon inquiry, the parents informed me, that the day previous, she had accidentally fallen upon her dinner basket, on her way to school, had hurt her neck in the fall, and had lain in a by-path helpless, until found by her school-mates, who brought her home in that condition. Upon examination, I found on the right side of the neck, a depression, and on the left corresponding side, a prominence in the region of the *atlas*; showing conclusively a sub-luxation of the bone upon the *vertebra dentata*. So unusual an accident caused me to pause ere I attempted to reduce it. Having informed the parents of the nature of the operation necessary to reduce the luxation, and the danger of so doing, they soon concluded that the operation had better be performed at the risk of life, rather than that the patient should suffer permanent deformity. As the case was urgent, I concluded that I should waste too much time in calling a consultation; inasmuch as my medical friends were too far off, some four miles at least. I allowed the patient to sit upon the table where I first found her.

Having placed myself directly in front of her, I placed a palm of my hand over each ear, the rest of the hand embracing the mastoid process and as much of the base of the head as possible, taking firm hold and lifting the head gradually, until I found that the whole weight of the body was being lifted from the table; at the same time inclining the face to its normal position, the reduction took place with an audible snap, attended with a slight exclamation on the part of the patient, a little tremor and paleness, which soon subsided. Not much pain, but considerable soreness, remained next day in the neck, which was readily removed by a stimulating liniment. On the third day I called to see my patient and found her perfectly well; has had no unpleasant sensation since.

The above case is another to be added to the few well-authenticated cases of luxation of the cervical vertebræ, treated successfully. The *Boston Medical and Surgical Journal* in the last volume, has from a correspondent several cases reported. Dr. South, in his edition of "*Chelius*," mentions a few cases. The number reported this side of the Atlantic is now greater than that reported by the English journals.—*Phil. Med. and Sur. Jour.*

## NEW INSTRUMENT FOR DEPRESSING THE LENS IN CATARACT.

At La Charité, M. Gerdy has introduced a needle, which he uses, to divide the posterior surface of the capsule; and depress the lens; it opens in two portions, and is somewhat similar to one lately invented by Mr. Bowman, for the purpose of removing any portion of capsule left after extraction or depression. We confess we do not see the advantage of M. Gerdy's needle in depressing the lens; but for other purposes, such as the formation of artificial pupil, we think it may be rendered of great avail. M. Gerdy describes it as cutting like scissors, "*leurs lames font l'office de ciseaux*;" and if so, we should like much to find our instrument-makers following the example of Charrière, the maker—since we should despair of such a feat in London as the manufacture of a pair of scissors with the form and point necessary for their introduction through the sclerotic into the posterior chamber, or even through the cornea to the iris.—*Prov. Jour.*

Is there any difficulty whatever in depressing the lens with a needle? These hook-em-sniveys" are all mere cutlers' toys.

## VOMITING IN PREGNANCY.

By GEORGE ROSS, Esq.

AN important debate having been lately held in the French Academy upon the propriety of inducing premature labour in cases of severe vomiting during gestation, I am prompted to send you an account of a case, in the hope that it may prove interesting to your readers. It would occupy too much of your space to go over the changing details of a case that was four months under treatment; I shall, therefore, limit myself to a general statement of its leading symptoms and complications.

Mrs. B., aged 32, whom I had been engaged to attend in her accouchement, sent for me on the 19th of May, complaining of inability to retain her urine, which passed from her at least every five minutes. She was also troubled with diarrhoea and sickness, but the incontinence of urine was the most urgent symptom. There was no pyrexia, but there was cephalalgia, and strong hysterical symptoms, and she had wasted considerably since I last saw her. On the next day after my visit, the incontinence of urine appeared to be relieved, but the diarrhoea was increased. For the relief of this symptom, I ordered chalk mixture and opium, which seemed to have a partially beneficial effect, and on the third day the vomiting in its turn became most urgent.

In consequence of the hysterical state of my patient, I found some difficulty in getting an intelligible history of her case; but now that the vomiting had become excessively troublesome, she told me that for three or four days previous to her sending for me she had been unable to take the least portion of food, and even rejected the smallest draught of cold water. She had now been six days in this state, and I began to feel some anxiety lest my patient, under a continuance of her symptoms, should die of starvation. For a long time also, antecedent to this, she had been troubled with harassing vomiting, though not equally exhausting; and between two and three months before she had a slight attack of scarlatina, caught while nursing her little girl, who had suffered with severity. Her solicitude and watching at this time had, doubtless, impaired her health.

It was now a question whether the induction of abortion should not be had recourse to; and on examining per vaginam, I found some fissures on the anterior lip of the os uteri, but the organ itself *in situ*. I refrained, however, from resorting to an operation on account of the extreme anxiety of both the mother and father to have a living child, and because I considered that she had sufficient strength to permit of a further use of remedial means.

The history of her past condition was unfavourable. Seven years before she had been delivered of her first child by one of our most eminent accoucheurs with the use of instruments, as I was informed; the child was alive, but since that time the mother had had seven miscarriages, always occurring about the sixth month; and her health had been so much impaired that for the last three years, she had been scarcely able to leave her house. The fissures on the anterior lip of the os and cervix uteri were probably the result of lesions occurring in her first labour. As it was probable that if she could be helped on to her full period, and afterwards suckle her child, her health might be restored, I resolved to give her the chance.

It is unnecessary to detail the symptoms from the time I was called in to the time she was safely delivered on the 10th of August of a living child. The following observations, however, should be noted. For the first two months of my attendance she continued with greater or less severity to be troubled with the symptoms she laboured under when I first saw her; but I observed that the sickness was generally most urgent when the incontinence of urine and diarrhoea were least troublesome, and *vice versa*. She became able gradually to take very small quantities of light broths and farinaceous diet, with a prospect of retaining them for a sufficient time to yield support; but it was only during the last month that she could take small quantities of animal food. For many weeks it seemed that my pa-

tient was literally existing without food, so trifling was the amount her stomach would receive. Her diarrhoea assumed latterly the dysenteric form, and continued up to the last day of pregnancy; the incontinence of urine abated, but a call was made generally once in every hour.

During the labour, which lasted about six hours, there was no vomiting, and with the exception of treatment required for the dysentery, there was no trouble with her in the "getting-up." She nursed her child, and in three weeks from her confinement was able to walk in the open air, and two days ago left London for the country to re-establish her health.

I need hardly add, that a great variety of remedies were employed; those, however, which seemed to exercise the most benefit were distilled vinegar and acetate of morphia for the correction of the vomiting, and an infusion of pareira and calumba with morphia for the relief of the incontinence of urine. She kept her bed in the recumbent posture during the whole of the eighth month, to which I attribute much of the relief she experienced about this time. Suppositories of opium were occasionally employed. The report of this case would have seemed much more brilliant had an operation been performed; but the result amply compensates me for my anxiety and forbearance. The speakers in the French Academy were almost unanimous in favour of the induction of premature labour in cases so severe as the foregoing; and I am aware that I ran a great hazard in persevering with treatment; but in all cases of this kind much must be left to the discretion of the medical attendant. M. Dubois says that extreme sickness during pregnancy, though destroying life, is purely physiological, and that a necroscopic examination shows no signs of organic lesion. I believe this statement to be true; certainly in the foregoing case, which is the severest that has ever come under my observation, there did not appear to be any evidence of organic lesion, except the fissured state of the os uteri already referred to. I had intended to have entered on the physiological phenomena of vomiting, both antecedent to and during labour, but I have already transgressed on your space at too great length.—*The Medical Circular*.

## PUNCTURE OF THE ABDOMEN IN TYMPANITES.

A case in which tympanitic distension of the intestines complicated with obstruction, was beneficially treated by puncture, has been witnessed by M. Labric, who has made it the basis of a thesis, in which he has collated and commented upon all the instances of the kind which he could find on record. In tympanites the gas may accumulate either in the intestines, which is the most usual site, or in the peritoneal cavity, which is a much more exceptional occurrence. The operation of tapping the intestines under these circumstances, is frequently performed in the lower animals, more particularly bullocks and sheep, in which, after a large repast upon green food, great gaseous distension of the stomach not unfrequently occurs. The veterinary surgeons perform the operation with a common trocar and cannula, and the relief is often immediate and permanent. Much difference of opinion, however, exists as to the propriety of the operation in the human subject, peritonitis being dreaded as a likely result; but M. Labric very justly objects to this apprehension, as uncalculated for, as in nowise more likely to follow tapping for tympanites than for ascites, in which latter disease its occurrence is quite exceptional. For the performance of puncture the needle and the trocar have been respectively recommended: the author, however, prefers the latter, taking care that it is of a small size, such as is used as a means of exploring doubtful tumours. The only precautions required is to choose the most prominent and sonorous spot, at which it is known that the bowels are closely in contact with the abdominal walls. The author relates his own case and three others. In all the relief was most marked and grateful to the patient; but as they were instances of insurmountable intestinal obstruction, in which the tympanitic distension was but one symptom, the ultimate result was of course fatal.—*Prov. Jour.*

## TREATMENT OF ALBUGO BY GALVANISM.

HAVING seen in some journal that in Russia and Sweden albugo in the horse had been removed by the aid of galvanism, M. Turk adopted the method in the human subject with the effect, he assures us, of greatly diminishing the opacity of the cornea. The case was that of a young girl, aged 13, who had been the subject of scrofulous keratitis, which left albugo of each cornea. That on the left side was not central, so that the child was able to see imperfectly; on the other eye it was so universal as to render her perfectly blind. She was considered incurable and had abandoned all treatment, when she came under the author's care for another affection, and he then determined to experiment with the galvanic battery.

He, accordingly, having set in action a battery of appropriate power, placed the zinc probe in the mouth, while with the copper or negative pole he lightly touched the cornea. The immediate effects were vertigo, nausea, and violent arterial pulsations, but these were soon subdued by a counter application of electricity to the lower extremities. The treatment was persevered in for forty days, with the result of considerably diminishing the opacity in both eyes, so that she was able to read with that eye which had been blind for more than ten years, while the other, though not cured, was so far benefited that the patient was able to follow her occupation of sewing. M. Turk farther says, that he has seen albugo in the horse removed in this way in two minutes!—*Prov. Jour.*

Fudge. This so-called *albugo* was the diffused opacity of the cornea caused by *corneitis*. It was cured by "forty days," and not by any such far-fetched appliance.

## DISLOCATION OF THE ACROMIAL END OF THE CLAVICLE.

THOMAS JENKINS, aged 21, admitted August 3, 1852, under the care of Mr. Green. An hour before admission he was standing in a narrow way, when a coal cart passed by, the wheel coming in contact with the outer part of the left shoulder, and pressing him against the wall. On examination the nature of the injury was at once evident, for the acromial end of the clavicle was plainly seen resting against the spine of the scapula, and under cover of the trapezius muscle. The part of the spine of the scapula where the clavicle was resting on, was nearly two inches from that part of the acromial process of the scapula to which it is normally articulated. Shortening of the distance between the neck and the shoulder was well-marked. In consequence of the support of the clavicle being gone, the shoulder came forward, so as to give the impression that there was some displacement of the head of the humerus. There was some contusion of the soft parts at the outer and posterior aspect of the shoulder-joint. The clavicle was almost brought back to its normal position, by keeping the shoulders back, and raising the arm. A figure-of-eight bandage was therefore applied, in the same manner as for fractured clavicle; and the arm was raised by a bandage under the elbow, and carried over the opposite shoulder. This treatment was continued up to August 21st, when he was discharged. There was but little deformity when he left the infirmary. This was an extreme case of displacement, for in most instances the clavicle is dislocated upwards on the acromion. There was the following circumstance to be noticed in this man. On the other side, the clavicle and the acromion process were not on the same plane, so that on the application of great force, this condition of articulation would, I think, rather tend to dislocation; whereas if the two bones had been on the same plane, the clavicle would have been most likely fractured.—*Prov. Jour.*

## REVIEWS AND NOTICES OF BOOKS.

A COMPENDIOUS HISTORY OF SMALL-POX. By HENRY GEORGE, Surgeon, author of an Essay on Cholera. London: 1852. 8vo. pp. 134.

THIS is the second edition of an essay published several years since with the object of calling the attention of the profession to certain local measures which the author has found of use in preventing *pitting* in confluent small-pox; and by the use of which he considers the danger of the disease to be lessened.

Previous to Mr. George's first publication, local applications were forbidden in this disease; it was the established rule to leave the pustules to themselves, and to interfere in any way with the progress of the eruption was considered bad practice. Mr. George showed not only that these were mistaken views, but he brought forward cases in proof of the value of local applications; and he has been in a great measure instrumental in bringing about the change in opinion which has since taken place, though the credit of the improvement has not always been awarded to him.

The volume commences with a concise and well-written history of small-pox, which extends to forty-four pages. The remainder of the essay is entirely practical, and is devoted to the "constitutional and local treatment of the confluent form of the disease." "When we consider (the author observes) the intimate connexion which exists between the surface and the internal parts of the human body, and reflect how the vital functions are often impaired, and even destroyed, by comparatively slight injuries and diseases of the former, we cannot feel surprised that in cases of confluent small-pox the constitutional disturbance should very generally assume a most malignant and unmanageable character."

"The innumerable suppurating processes going on, the exposure of large portions of such a very important texture as the cutis, with the consequent pain and suffering, are circumstances which, on reflection, would rather lead us to feel surprise that any of its objects should escape, than that the mortality of the disease should be so inconsiderable. I am induced from observation to believe, that in the management of the local features of this complaint, in a great degree, depends the security and comfort of its victims. That the phenomena presented to us in the different stages of confluent small-pox, are such as exhausting processes, and continued bodily suffering, would, under any circumstances, uniformly produce, and consequently doubt whether this tumult, or, to use another phrase of Sydenham's, this ebullition in the constitution, is not referrible to the nervous rather than to the vascular system, and whether it bears the genuine stamp and character of fever."

Among the reasons which lead the author to suppose that in fatal cases of small-pox "the result is attributable to the incapability of the powers of the system to complete the various exhausting, and to endure the painful processes which are going on"—1st, and chiefly the experience that in these cases a mode of treatment may be adopted with the greatest advantage which would be found to be highly injurious in any of the forms of fever; and 2ndly, the absence of one of the most distinguishing characters of fever, the suppression of the different secretions."

The local treatment recommended by the author consists in covering the body as completely as possible with any absorbent powder; he generally employs calamine. The advantages which follow the use of this dressing in the early stage are, to moderate the violence of the local inflammation and to prevent the painful tumefaction of the common integuments. "After the calamine has been applied some hours, a very sensible difference is to be observed in the appearance of the parts so covered, the areola of each pustule being much less distinctly marked."

The following are some of the author's conclusions under this head:—

"That to cover the surface of the body, on the commence-

ment of the disease, is to prevent the painful tumefaction of the common integuments, and in no trifling degree to control the violence of the local inflammation; that when the pustules are fully ripened, you may, by partially destroying the cuticle of each, completely heal them, the attached cuticle shrivelling, and in a few days falling off, leaving the skin perfectly smooth; that unless the surface is again covered with the powder, an inrustation forms on the site of each pustule, which on being removed exposes a slight depression that I have strong reason to believe in time wears away; that where, from neglect of this practice at the commencement, large portions of exposed cutis are to be met with, they also may be healed in the space of a few hours, or at least completely deprived of their sensibility by this application; that the advantages attendant on this mode of local treatment are, 1st, it prevents those deformities occasioned by ulceration of the skin; 2nd, it rescues the patient from those sources of danger to which, from the eighth day, he is exposed; the consequences of the powers of the system being in a great degree exhausted, though distressing processes still require completion, and from being subjected to those agonizing sufferings which an exposed cutis uniformly produces."

The remainder of the volume is occupied with cases illustrative of the author's views and opinions, most of which have already appeared in print in the pages of the *London Medical Gazette*. We think the author's essay well timed, and likely to be of service by recalling attention to so simple a means of diminishing the suffering, and lessening the chance of deformity, in this loathsome disease.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, OCTOBER 13, 1852.

### OPENING THE SESSION IN LONDON.

OUR "London Correspondent" tells in another column of this day's publication how the decoys and nets for Michaelmas geese have been handled on the Thames this first week of the "season;" and be the success of sportsmen what it may, it is obvious that a keen relish for the game prevails, and a hearty resolution to turn every method of capture to account. There is something tempting for all, whether gander, goose, or gosling; chaff for the young birds, a whistle for last year's brood, and substantial grain in the shape of premiums, scholarships, and exhibitions for old and wary cacklers. The breeders, too, have their share of attention in the shape of "soirées" and "conversaziones," including the less substantial creature comforts of cakes and coffee. From a contemporary on the spot we learn additional particulars. At Bartholomew's, that "venerable institution," "the same crowds of anxious-looking first-year's men, more advanced and shrewd pupils, and former *alumni* of mature age," mustered "as friends and supporters," giving "enthusiastic reception to medical officers and lecturers," "terrific as fire-arms plied by explosive propensities;" and when "a popular name acting on the touchhole brought forth the volleys," amounting, doubtless, to a clamour which "rattled the welkin's ear and mocked the deep-mouthed thunder." Be all this, however, as it may, it appears that Dr. BLACK, who "delivered the Introductory," performed the duty to the satisfaction of all, and that after he had finished—

The company adjourned to the great hall of the hospital, where refreshments were served out. The *conversazione* was of a very animated kind, much attention being attracted by valuable specimens of materia medica, microscopes, and surgical instruments and appliances. The visitors who had not seen this hospital for some years, must have been greatly struck by the handsome appearance of the four structures

forming the quadrangle, which are now quite rebuilt, and look defying ages to come. Besides this outward appearance, many improvements have been introduced in the interior, in the shape of additional side rooms, kitchens, and the raising of the roof of the upper or veneval wards.

Shall we venture to say "*si foret in terris rideret Democritus*" at all this; or in other words, what would "glorious JOHN" say of it, if he was in the land of the living. As we write, the comical ABERNETHIAN sneer and shrug falls full upon the retina of our mind's eye and tickles our risibilities, as oft it did before; yet we must not be fastidious or hypercritical. The geese of '52 are not to be coaxed with blue-pill and biscuit: they must be made to gape before they are crammed. At Guy's—

The attendance of pupils and friends on the occasion of Dr. Taylor's introductory lecture was very numerous, equally so with former years,—and the theatre had a very animated appearance. The contrast between the beaming physiognomy of the alumni, and the much less fiery aspect of even the younger members of the profession, was very striking: with the former, all was liveliness, hope, and trust in the future; with the latter, who have already tasted some of the bitters of a medical career, there was an evident thoughtfulness, and a seeming melancholy glance at the past. A very cheering sight before entering the lecture-room was the handsome centre and southern wing of the new building, now almost completed. The pile is of a very commanding aspect, lofty, massive, and fully in keeping with its noble destination. Much good is expected from the lofty ventilator, which forms a conspicuous part of the building. The lecturers and medical officers of the hospital were warmly greeted as they entered the room. It must have been very gratifying to them to be thus received, not only by the pupils, but by a great proportion of former students.

But what means this sly hint?

We were sorry to find that two or three of the medical officers were absent. This non-attendance, it is hoped, was unavoidable, for on such an occasion the pupils should see *all* their guides and advisers before them, joining in the good work, and encouraging them at the outset, or in the progress of their studies.

Is it a rebuke administered to some colleague in sauk or pet who has not learned that "nobody's missed;" or being in ornithological vein, may we ask—Are there birds in London, too, who befool their own nests, or "sell" their household to the foxes for present ease and future comfort? Perhaps, however, we do but see a dagger in the air, and so let it pass. At George's—

No regular introductory lecture was given at this school, but, in accordance with the custom at this institution, the prizes awarded for the past session to the various successful candidates. In some remarks preliminary to the distribution of prizes, Mr. Cæsar Hawkins took occasion to comment upon the great advantages which students of the present day possessed over those who studied some years back. He alluded more particularly to the incentives to exertion which existed in that school in the shape of scholarships and prizes.

And then came the distribution of "the scholarship," Sir BENJAMIN'S prize, the Company's commission, and sundry *immortelles*, in the shape of premiums adjudged to Brown, Jones, and Robinson. Mr. HAWKINS, however, addressed some pertinent observations to his hearers, of which we regret our inability to give more than a brief summary:—

He impressed on them the absolute necessity of patient, careful, and industrious study, without which, success in their profession was hopeless; of cultivating gentlemanly habits, feelings of humanity and commiseration for their suffering fellow-mortals; good temper; and, above all, religious sentiments and practices. He pointed out as amongst the books which should be found in every medical student's library, Hippocrates, Celsus, Sydenham.

Translations we conclude are here meant, for until the doors at Lincoln's-inn-fields are closed against those re-

joining in "the vernacular" exclusively, the originals must prove but book furniture. At King's College—

Dr. Todd spoke of the improvements which had been effected in education since the College had been first established. Originally the student had had so many lectures to attend in a day, that he had scarcely time for study, and his mind was distracted by their multiplicity. Thanks, however, to the Society of Apothecaries, who had done much to improve education, the pupil now only required to attend three lectures a day, and these were so arranged as to afford him the greatest possible opportunity of deriving advantage from tutorial instruction—a mode of study which that College had endeavoured to foster and maintain. He spoke in high terms of the rewards for industry which the College authorities held out, not so much in respect to prizes, which had their drawbacks, but with regard to scholarships, the working of which they had found to be most beneficial. The fund for scholarship now amounted to £520 per annum. These scholarships were not intended for poor persons, but for those who had distinguished themselves, and had passed an examination. Religious instruction was essential to a student of that institution, and the College was founded on that ground.

"Thanks to the Society of Apothecaries!" What will the Greeks, erst of Warwick-lane, say to this? Tell it not in Pall-mall, let it be proclaimed not in the House of Somerset. The Blue-bottle Doctors of England and Wales presiding over the educational destinies of Royal Colleges, and elbowing from their chairs the heads of Universities and the Presidents of Emporiums of legal Licences!! What will the congratulating Doctor's reverend brother here in College-green say to it? We have often repeated the now accepted axiom, that there "is but one step from the sublime to the ridiculous," and here is another example. But a light breaks in upon us. Perhaps after all, there is not such a wide difference between HIPPOCRATES and GALEN. Here in Dublin, we know, that extremes sometimes meet, and it may be that in London a King's College may virtually become the educational subordinate of an Apothecaries' Hall. Our limits do not, however, permit us to complete this our sketch of the rival medical theatres of London; perhaps we may resume it: enough, however, is given to enable our readers to form some opinion on the subject. For ourselves, notwithstanding our bantering, we would not have it supposed that we wish to disparage our neighbours in this behalf; on the contrary, we see cause of congratulation in the scene before us. Competition there is, and necessarily the fruits of competition, good and bad, but none of the cheap and nasty competition, which formerly disgraced the modern Babylon. No monster certificate shops, no long credits, no "lumping" system, no substitution of grinding and cramming for proper instruction; nor yet, again, does it appear that *anser juvenilis* is worried by rival foxes, or that hospitals are troubled by earthstoppers and whippers-in. Moreover, we see cause of congratulation in the observance of a strict neutrality, where strict neutrality should be religiously observed, and the absence of ostentatious displays of intimacies, where no intimacies should exist. Above all things, we rejoice to see no resort to meretricious allurements in the shape of sham Diplomas or cooked Degrees; and best of all, we see an honest ambition to raise humble institutions to the rank of the more lofty, rather than to drag down high ones to the level of the lowest.

MEDICAL LIFE IN LONDON.

SCHOOLS AND COLLEGES.

London, October 8, 1852.

THE "Introductories" are off our spirits. The schools, according to immemorial fashion, hard at work for the season. What a feeling of joyousness should each returning spring-time of diplomas and "learning the bones" bring with it, if everything else in the profession went on with the same good understanding, if the practice of surgery and medicine, in fact, were what they ought to be, and what a little solicitude on the part of those in authority might easily make them—professional and respectable; with many changes in editorial ways here just now, and sundry improvements in Guy's, at the College of Surgeons, Paddington, and King's College, all impending. The cholera not yet arrived, as predicted to the day, and the government favourably inclined to assist all professions. Let us hope for a "good time coming," when, if not actually represented in parliament, we shall have our claims preferred, when we shall have, perhaps, more unanimity and less diplomas, more mutual good feeling while exposing what is wrong, from a mutual understanding as to what will benefit all branches of the profession, and set forward what is right—lead, in a word, to its consolidation, not to its crumbling to ruin: making medicine the same in the cloistered halls of Oxford and Cambridge as in their rival sister, Trinity College, Dublin; and surgery what it was left to us by John Hunter, not the sad jumble of all unearthly things our present arrangements have made of it. The "Introductories" have been fair average specimens of the dialectics usually displayed on such occasions; the men seemed full of their subject, and the benches of ardent and admiring hearers. Learning to the popular weakness of not being in two places at one and the same time, we shall not be expected to tell of all the riches displayed on the present occasion. Judging of Hercules from a single member or two, we would say the lectures at Guy's and Bartholomew's were very good. Dr. Black, at the latter school, at seven o'clock in the evening, read the pupils a most valuable essay—on their duties and privileges—as warden; after Mr. Paget, no one was, perhaps, so fitted for the occasion. Tea and half an hour's talk wound up the entertainment. At Guy's, as usual, everything was also *selon les regles*.

Dr. Taylor has lately succeeded from his able editing of the *Medical Gazette*. Our periodical literature here has lost two other able and accomplished writers, a fact a good deal discussed just now. Dr. Carpenter's sedulous and untiring industry in the arrangement of that most valuable journal, the *Medico-Chirurgical Review*, has long been a subject of wonder, taken in conjunction with his duties as lecturer and examiner, and the almost endless labours of re-writing his large work on "Physiology." The change in the editing of the *Medical Times* has been not without a little surprise, and we would say also not without a little concern that a successor may be found equal to the duties so ably fulfilled by the highly accomplished and brilliant writer who lately conducted this journal—one who himself has added not a little to the advancement of professional subjects, and now promoted to a larger sphere of practical usefulness, will not fail still to favour us with his *arundines eam*—his medical and physiological exercises, so replete with interesting facts and observations. We have the best reason for knowing the late editor of the *Medical Times* was an ardent admirer of the Dublin School, and did much to make it known in England. Your men, like Graves, Stokes, Crampton, Jacob, Churchill, Bellingham, the Kennedys, Marsh, Cusack, are here in London identified with specific subjects; and if in ophthalmic, surgical, obstetric, and general medical subjects, many prefer Dublin authorities, it is because the Dublin School has gone the right way about learning and teaching them.

The most disgraceful characters brought up before the

London police officers sometimes say they are surgeons, with the same equanimity they would say shoe-maker or paper-hanger. At a Dublin police office the same vinous gentleman might as well say he was Llaima of Thibet as Dublin surgeon attached to an infirmary. To one member of the college already, such exhibitions are regretful in the extreme. The cure for all such evils is sure to follow, however, on their being widely known. A wide-spread feeling exists in England at present to remodel all our seats of learning. The Report of the Oxford Commissioners, which the late much lamented Chancellor was engaged in reading a few days before his death, pretty clearly exhibits the changes necessary to place that Institution on a level with the requirements of the age. A new parliament, if it have none of the traditions a new broom, will be certain to do some permanent good, and amongst the most crying reform necessary is medical reform. It may be saying this for the hundredth time to state the fact, and it may be very useless to try and disturb old and firmly rooted evils, but the existence of medicine as a science would seem to depend, for the future, on mutual cooperation of colleges for the common good; not each college trying to sell its wares in the most cheap fashion it can. Without uniformity in the *curricula* of our surgical colleges, little advancement will be made. Two clauses in the Pharmacy Act to prevent chemists prescribing would save many lives, and add very considerably to the respectability of practising surgeons; while a properly recognized legal title, as on the Continent, of each faculty, so to speak, in one specific form, of surgeon, physician, general practice man, &c., and no other, would tend immeasurably to advance the material interests of the profession. Sooner or later the thing will be done, or chaos irrecoverably confound all professional distinctions.

An articulated pupil of the college, of course, every one is aware, may or may not, as he pleases, undergo a kind of classical examination, and serve a sort of apprenticeship to one of the "crack" men, in which the most exigent requirements will be to dance a good polka and tell sherry from buccellas. He may, under the special benison of excellent Mr. Lawrence at Bartholomew's, or with a sort of wierd attachment to Mr. Bransby Cooper at Guy's, amble through the wards for his two or three years; or again matriculate at King's College, and go through his dithyrambics and make Greek verses of poor Shakspeare, when he should be making colocynth pills, or learning the possible qualities of tartar emetic. But this is not what we want. He will tell you, when he writes incompatibles every hour in prescriptions (if he is able to write a prescription at all), that he does not pretend to know drugs or physic. This, however, is not what the profession now-a-days is in need of. We require the men entering the profession to feel the responsibility they are undertaking: it is to be the business of their lives. Venus, Paphos and Gridos, and prosody are excellent in their way; we require a classic examination for every man going up to the London College of Surgeons; and an apprenticeship as a *sine qua non* of at least four years.

We want no class or aristocrat "dressers" in hospitals, on the one hand—too many of them from sheer fashion good for nothing—or, on the other hand, do we much stand in need of the members of the college who fill the saddening and mournful list of railway porters, omnibus men, &c. We require, at present, if a man is to be a surgeon, he is to be a surgeon—no pinchbeck cameo out of the surgical intaglio in Trinity College, or in the staid pocket of Mr. Belfour; if he is to be a physician (a diploma curiously enough seldom thought of, though the majority of ailments are medical), he will, at least, know a little of medicine along with German town-life and legends of the north of Scotland.

It is an injustice to the Dublin College of Surgeons' diploma and our own University M.D.'s for things to continue as at present.

## PAYMENT OF MILITIA MEDICAL OFFICERS IN ENGLAND.

Among the regulations issued from the War-office, we were hardly prepared for those which show in how high estimation the authorities hold their Militia Medical Officers. Of this class, a large number hold their commissions without deriving one tittle of profit or advantage from them, except when called out on active service, and in the interim are engaged in the pursuit of a laborious and ill-paid profession, without any restriction to residence at headquarters. Under such circumstances, an unsophisticated mind would assume that the War-office had no claim on their services, except when enrolled, they being at other times neither more nor less than private practitioners; and moreover, that they were not liable to enrolment except simultaneously with all other officers of their regiments. This, however, is not the view taken by the Secretary-at-War. His regulations direct that the recruits shall be inspected by a militia or military medical officer if available; for the latter no remuneration is provided, obviously on the ground of his being on full pay *de die in diem*, and for this there is some show of right, extra though the labour be; but as regards the former, no such title exists; he is to receive 11s. 4d. per diem only on such days as he is engaged in inspections, but if the number in any day be fewer than five, he is allowed 2s. 6d. each; if fifty, no more than 11s. 4d. Nor does the monstrosity stop here; when two, or one private practitioner conducts the inspection, the circular grants him 2s. 6d. for each recruit submitted to him; however great the number be, so that supposing fifty men to be surgically examined in any given day, the regimental surgeon would receive 11s. 4d., or less than 3d. each; a private surgeon, £6 5s., or 2s. 6d. each; and the very clerk, who does the mere scribbling, £2 10s., or 1s. each! We distrust our own senses in contemplating these extraordinary facts; we torture our heads in vain for the species of ratiocination whereby to reconcile them with the rudest notions of honesty; the clue to the enigma is a spirit in the vasty deep that will not come when we call it. Our dull comprehension maintains that as regards this particular duty, and at this juncture of time, both those medical gentlemen are on precisely the same footing of private practitioners; and that if the remuneration of the one be not excessive, that of the other is a sheer robbery of an individual whose commission is made the substitute for a pitch-plaster. But when the mere scrivener is awarded nearly five times the remuneration of the man of science, on whose talent and education so important a duty devolves, we admire the boldness and ingenuity that could devise and execute such perfection of injury and insult. Nor does it end here. The regimental surgeons are required to accompany the adjutant on tours of inspection, to be absent all day from his private practice for the magnificent sum of 11s. 4d., besides travelling expenses, supposed to leave no profit. The Secretary-at-War cares not one jot how much the surgeon loses in his permanent business; he matters nothing to him how this gentleman lives and maintains, his family 344 days in the year, so that he may claim his service at any other time for a sum not exceeding 11s. 4d. per diem! This is the maximum a militia surgeon ought to earn in any single day, according to the estimate of the Secretary-at-War. The militia surgeon is urged to submission by another regulation, which doles out to him 7s. per week per 100 men for medicines during the period of enrolment and training; so that he is deeply interested in seeing that the men enlisted are not liable to more than an ordinary share of sickness. We wish we could hope that these provisions were an oversight in the pressure of official business, and not a refinement of the insult to an honourable profession, in consigning naval assistant-surgeons to the cockpit. *Lancet*.

### PAY OF MILITIA SURGEONS.

I will adduce, as an exemplification of your statement, that I have been engaged for three days as follows:—On the first day I examined more than fifty recruits, which occupied between four and five hours (the best part of the day); the second day I was engaged about three hours; and the third travelled forty miles by rail (the railway expenses only being allowed), which occupied seven hours, and for which, as you are aware, the pay is 11s. 4d. per day, with an allowance of 5s. for my expenses at the inn on the last day. Now, having a very fair private practice, you can easily imagine to what a sacrifice I am subjected for the paltry pay above mentioned. I really can only account for the above regulations of the War-office as having been hastily formed, without the slightest knowledge as to how a militia surgeon, entirely de-

pendent on his pay, could possibly exist even for so short a time, or how he could survive the remaining months of the year, after the enrolment and twenty-one days' training had concluded (the pay then ceasing), or how a private surgeon could afford to neglect his practice for so paltry an inducement. I do trust that through such able advocacy as your own, the Secretary-at-War may be induced to see the error of his way, and speedily remedy such injustice.—*Letter in Lancet.*

We feel more inclined to laugh than weep at the "grievances" of these sodgering doctors. If gentlemen "having a very fair private practice" will leave it to strut in scarlet they must take the consequences. If, as Ollapod says, "gallipots give way to gallant feelings, and Galen is gagged by Bellona," the Secretary-at-War does well to avail himself of it.

# IMPORTANT ANNOUNCEMENT RESPECTING FEES TO MEDICAL WITNESSES.

The following is a copy of a letter received from the Lords of the Treasury in reply to a memorial from the medical men of Wakefield, on the subject of fees to medical witnesses at assizes and sessions.

Treasury Chambers, July 5, 1852.

Sir,—The Lords Commissioners of Her Majesty's Treasury having had before them a memorial signed by you and several physicians and surgeons practising at Wakefield and in its vicinity, in which you complain of the inadequacy of the allowance made to medical witnesses, their Lordships desire me to state that the whole subject of the expenses of criminal prosecutions at the assizes and sessions, including the allowances to medical and other witnesses, is now under the consideration of Her Majesty's Government. Their Lordships would not, therefore, feel warranted in deciding upon the claims of any particular class of witnesses, until they shall be prepared to come to some general settlement of the whole matter.—I am, sir, your obedient servant,

GEORGE ELEMETH.

As this subject has often caused complaint amongst us here in Ireland, those interested in the matter should now attend to it. It gratifies us to find that such questions begin to receive the consideration they demand. Some months ago a memorial from Dr. Z. Johnson of Kilkenny, was forwarded to the Irish Government by the College of Surgeons, praying relief for inadequate payment for medical services to crown witnesses, which was promptly entertained by Mr. WYNN, the Under-Secretary, and better arrangements have in consequence been made. For ten years before complaints had been made on this score without the slightest relief.

## CORRESPONDENCE.

### BITTER BEER.

MESSRS. ALLSOPP AND SONS AND DR. GLOVER.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—I perceive in the *Medical Press* of September 29th, a letter from Dr. Glover of Newcastle to Dr. Robertson of Edinburgh, quoted from the *Monthly Journal of Medical Science*. I can have no fault to find with your insertion of that letter as an article of medical intelligence, nor should I venture to interfere with your unbiassed judgment on the matter, had I not some reason for supposing, by the peculiar heading, and other circumstances of the paragraph, that your respectable journal has been made the tool of a certain unworthy and jealous party, which has given a malicious and widespread circulation to every possible calumny against our firm. The enclosed letter, addressed to the editor of the *Monthly Journal of Medical Science*, which appears in that periodical for the present month, will afford every satisfaction on the matters touched upon by Dr. Glover that a candid mind can desire. I appeal to your respect for truth and sense of fair play for its insertion accompanied by this letter.

You will observe that delicacy towards Dr. Glover, and

consideration for his high position in the profession, prevented me from replying to his letter previous to communicating with that gentleman, and obtaining his permission to publish his communication entire, neither would it have been becoming to have made use of any other medium for reply than the one in which the charge had first appeared. Hence the delay of a month.

But no consideration of delicacy, no respect for professional character, no desire to come really at the truth, no sense of fair play has served to prevent those who thought it would answer their purpose of perversion and misrepresentation from sending round to all the medical press and the profession paragraphs putting a most offensive construction upon Dr. Glover's letter to Dr. Robertson, and the heading of which conveyed a direct charge against us, to which we are known not to have laid ourselves open.—I am, sir, your obedient servant,

HENRY ALLSOPP.

Brewery, Burton-on-Trent, October 9, 1852.

In an evil hour have we become, as the poet saith, "bemused in beer." It may prove as unlucky an affair as the "Sligo Controversy." But we can assure our correspondent here, that "the tender lamb that never nipped the grass is not more innocent" than we of complicity with the enemies of his ale. For beer of all kinds we entertain a strong partiality; convinced that amongst the "remedies for Ireland," there is not one more promising. The substitution of it for logwood and rhatany by one class, and for whiskey by the other, might do more for us than all the "religion and politics" in the newspapers. When we inadvertently used the "peculiar heading" complained of, it was not beer we were thinking of, but Baron LIEBIG; whose name, by some unlucky mischance, so often flits within the range of our editorial vision in dubious guise. "The enclosed letter," above alluded to, our printer tells us cannot, by any contrivance, be squeezed into our columns, already filled for press! We must therefore reserve it for our next.

## THE DISPENSARY ACT.

(Extract from a Letter of a Correspondent.)

We do not here complain of having to attend farmers with holdings of forty acres. In my locality, and I may add other districts in this union, the issue of tickets is rather too limited. It certainly is not an easy matter to draw a line of demarcation between the class entitled to relief and those whose circumstances disqualify them from receiving gratuitous aid. The position generally of the small farmer is any thing but comfortable; he may have a cow or two, and yet be little removed from actual want; in truth, he is a poor struggling man. It was a great mistake admitting an illiterate class upon their committees. Under the management of such men, a sufficiently extended relief will not be afforded. Sympathy for the sick poor does not concern them; economy is their sole guide. Cheap doctors and cheap physic! In this union, thanks to a few rational thinking men, a salary of £100 was fixed for the medical officer. Not so, I regret to say, in many other unions.

TO THE EDITOR OF THE MEDICAL PRESS.

Sir,—Having seen in your last number of the *Medical Press* a letter signed "A Constant Reader," commenting on the conduct of the Poor-law Commissioners, in sanctioning the appointment of one medical officer to two dispensaries, in reply to which I trust you will allow me, through the same channel, to offer a few remarks.

Previous to the passing of the Medical Charities Act, the salaries of the medical attendants of dispensaries varied from £80 to £100 a year; for this they had to attend to the

small farmers, the dependents, and servants of many of the subscribers, as well as the labouring class. However, from famine and emigration, it is well known that the population in Ireland is much reduced, consequently all private practice is in a great measure diminished; and if medical men previous to the passing of this act were able to attend efficiently to two dispensaries, why not do so now?

At the late meeting of medical attendants held in Dublin previous to the passing of this act, it was distinctly understood that existing rights should be preserved; and I have no hesitation in now stating, that had those who then held more than one dispensary, and were the principal agitators about this act, been aware that their rights would not have been preserved, *this bill would never become law*. The Commissioners I consider all highly honourable minded men, and am certain will carry out the spirit of the act in preserving the existing rights of all medical men, particularly when proved to them capable of doing their duty efficiently.—I am, sir, your very obedient servant,

ONE OF THE LATE COUNTY SECRETARIES.

October 9, 1852.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—I have read in your last publication the letter of "A Constant Reader." He appears so dissatisfied with all the parties concerned in the election (including even the Poor-law Commissioners), that I think he must be the beaten candidate. However, he states that he is willing to give the names and localities; and, in order that we may investigate the matter and come to the facts of the case, I shall feel obliged by your calling on him for them, and publishing them at your earliest convenience. Hoping you will find space for this in your next, I am, Mr. Editor, your obedient servant,

October 10, 1852.

M. W. HANLON, M.B.

**TANNIN IN HOOPING-COUGH.**—Dr. Brewning employs tannin, in the following combination, in cases of whooping-cough:—R Tannini, gr. 1-6th; acid. benzoic., extract. belladonnæ, utr., gr. 1-12th; pulv. rhei, gr. ij.; pulv. gum. acaciæ, gr. xij. M. Fiat pulv. The powder may be given three or four times a day. For a very young child, half the dose twice daily will be sufficient. In a few days the severity of the symptoms usually diminishes, and the character of the attack changes. If the primæ viæ require clearing, an emetic dose of antimonial wine should be first administered. If the disease does not yield in a few days, and the periodicity of the attack is well marked, one or two grains of hydrochlorate of quinine may be substituted for the rhubarb. He recommends, as a domestic remedy, the simultaneous use of a tea of the flowers of the common primrose, with equal parts of inspissated crab-juice and sugar-candy.—*Brewning in Deutsche Klin and Prov. Jour.*

#### OBITUARY.

At Ballymahon, on the 10th ult., George Coreoran, Esq., M.D., deeply regretted by a large circle of friends and acquaintances.

On the 3rd inst., at 32, Upper Mount-street, James Barlow, Esq., M.D., late Surgeon 5th Dragoon Guards.

On the 4th inst., at Markethill, J. T. Monypenny, Esq., M.D., for thirteen years Surgeon of the Newtownhamilton Dispensary.

A few days ago, Mr. John Stokoe, surgeon, late of Durham, who served in the British Fleet at the battle of Trafalgar, and was subsequently appointed surgeon to Napoleon at St. Helena, died suddenly at his hotel, just after he had ordered breakfast. Deceased had many souvenirs given him by the ex-emperor.

#### PATHOLOGICAL AND PRACTICAL OBSERVATIONS ON STRICTURES, AND SOME OTHER DISEASES OF THE URINARY ORGANS.

By FRANCIS RYND, A.M.,

Fellow of the Royal College of Surgeons in Ireland; Surgeon to the Meath Hospital and County of Dublin Infirmary; Consulting-Surgeon to the Coombe Lying-in Hospital; Her Majesty's Medical Superintendent of Convicts in Ireland; Member of the Royal Medical Society of Edinburgh, of the Pathological Society, &c. &c.

"In this treatise, the causes, nature, and symptoms of stricture are explained; and its consequences, including disease of the bladder, retention of urine, and abscesses in the perineum, described. The treatment, both local and constitutional, is laid down; and the management of the catheter and bougie fully detailed. Disease of the prostate gland is also investigated, and its treatment considered. It contains in brief space, and at a moderate price, much valuable and instructive matter touching a subject which no surgeon can overlook. To us it appears a useful addition to our stock of information on this subject, and creditable to Irish surgery."—*Medical Press*.

"No volume was ever more correctly named according to its contents than that which is now before us; the diseases of which it treats are described from Nature, the views which it propounds are based on pathological science, and the treatment recommended is derived from an extensive practical acquaintance with the almost endless forms under which diseases of the urinary organs present themselves to the surgeon. We know of no work that presents such comprehensive or such admirable rules on the subject of treatment."—*London Medical Gazette*.

"The book is very carefully written, and may be consulted with advantage by those who are desirous of refreshing their knowledge, as also by the student."—*London Journal of Medicine*.

"The subject of fistula in perineo and its complications are treated of in this book in a remarkably clear and judicious manner. The remarks, &c., may be read with profit by all reflecting surgeons. It is, without doubt, an able and thoughtful production, and has our cordial recommendation as one of the best of the modern contributions to this branch of surgery."—*British and Foreign Medico-Chirurgical Review*.

"There is much that is good, both as regards the matter contained, and the manner in which the work is written. The remarks upon forcibly penetrating an impermeable stricture in retention, are excellent. There is much sound and valuable matter in this book."—*Lancet*.

"The practical precepts with which it is replete will amply remunerate the reader for the time expended in its study. We again repeat it as our deliberate opinion, that these 'Pathological and Practical Observations on Stricture' reflect great credit upon the author."—*Dublin Quarterly Journal*.

"We have been much pleased with the perusal of this work: it is full of sound practical research, and contains much that will prove valuable to the surgeon."—*Medical Times*.

"It is eminently practical, which is the highest praise that, in my opinion, can be given to a surgical essay."—*Sir Philip Crampton's Letter to the Author*.

"Your book is an important addition to the series of Meath Hospital Works."—*Dr. Stokes's Letter to the Author*.

Longman, Brown, Green, and Longmans.

**ALLSOPP'S PALE ALE AND DR. GLOVER.**

THE wide circulation given to a statement of a London medical journal, tending to invalidate the expression of Dr. Glover's opinion in favour of Pale Ale, compels Messrs. ALLSOPP and SONS to connect this remarkable distribution of a calumny with other insidious attacks upon their firm, which they have reason to know proceed from an unworthy and unneighbourly jealousy.

Messrs. ALLSOPP and SONS, in reply, deem it their best course to adopt the same line of conduct as in the case of the similar perversion and mutilation of Baron Liebig's meaning, so indignantly repudiated by that eminent man himself. They publish, therefore, without abridgment, the letter they received from Dr. Glover (having his permission to do so); a letter the more valuable because it was not intended for publication, and an evidence of that learned chemist's just appreciation of Pale Ale, written, as Dr. Glover himself says, in an unguarded style, and not meant for publicity:—

*Dr. Glover to Mr. Allsopp.*

"Newcastle-on-Tyne, April 11.

SIR,—It was not my intention, in writing the hasty note to the *Lancet*, to cast any reflections upon, or to implicate, in any way, respectable brewers of Pale Ale.

When I first saw the statement about the alleged use of strychnine in bittering ale, I looked upon the assertion as incredible, both on account of the price of the drug and the symptoms it would create; but, on experiment, I found that strychnine possesses such wonderful bitterness that it might perhaps be used as an ADJUVANT, at least by UNPRINCIPLED PERSONS. In short, my object was simply to show that the thing was not altogether so impossible as it appeared at first sight to be.

My opinion is, that hops should not enjoy the exclusive privilege of being used for bittering beer; but I do not pretend to discuss the point with practical men.

I know there are bitters which might be used beneficially, in a medical point of view.

With regard to analysing your beer, my time is taken up, so far as analysing and chemistry are concerned, with two kinds of inquiries—1st, those which are purely scientific; and 2nd, those which are profitable. If you wish me, in the latter capacity, to analyse and report on your beer, I, of course, can have no objection.

I have to prepare for an absence of three or four days tomorrow, and so beg you to excuse me replying to the letter of Mr. Bottinger, for which I am much obliged.—Yours, &c.,

(Signed)

R. M. GLOVER.

H. Allsopp, Esq.

P.S.—I presume you will hardly expect me to write to the *Lancet*. However, I shall be at home on Thursday evening, and most assuredly I have no desire to say anything which could weaken the confidence of the public in your beer. But that I am not now in the habit of drinking Bitter Beer, I should be glad to show my confidence by drinking plenty of it."

MESSRS. ALLSOPP and SONS beg to refer to the letter of Mr. Henry Allsopp on this subject, in the *Monthly Journal of Medical Science* for October, in the concluding paragraph of which it is said—

"I inserted Dr. Glover's good-natured remark on my Bitter Beer as an 'incidental testimonial'—no more. I never called it 'a certificate,' nor did I apply to him, or any other medical gentleman, for one. I am not responsible that such a construction has been placed upon the off-hand expressions of good opinion which have been sent to me from all quarters."

Messrs. ALLSOPP and SONS, in conclusion, wish to draw the attention of the public and the trade to the fact, that, by this disingenuous system of attack, and the perversions of facts adopted against them, they are unwillingly drawn into that publicity the courting of which is made an accusation against them.

Burton-on-Trent, October 8, 1852.

**PROFESSOR LIEBIG'S OPINION OF ALLSOPP'S PALE ALE.**

"The specimens of your Pale Ale sent to me, afforded me another opportunity of confirming its valuable qualities. I am myself an admirer of this beverage, and my own experience enables me to recommend it, in accordance with the opinion of the most eminent English physicians, as a very agreeable and efficient tonic, and as a general beverage both for the invalid and the robust.

JUSTUS LIEBIG.

Giessen, May 6, 1852."

 Messrs. ALLSOPP'S Advertisement continued:

**ALLSOPP'S PALE ALES.—BARON LIEBIG ON CERTAIN RECENT ANONYMOUS ADVERTISEMENTS.**

MESSRS. ALLSOPP and SONS have great satisfaction in being enabled to publish the following extract of a Letter just received, dated Munich, 12th September, 1852, from Baron Liebig to Mr. Henry Allsopp, Brewery, Burton-on-Trent:—

"To my great astonishment and concern, my attention has lately been called to several anonymous articles and advertisements headed by my name, such as in the —, whose author altogether misrepresents the motives of my remarks, and even goes so far as to say, that I had never analysed your beer, nor perhaps ever tasted it in my life, and to allege a retraction on my part of the original statement.

I emphatically declare that I had not the slightest knowledge of these anonymous articles, the contents of which I entirely disapprove of; and that in every respect I adhere to the statement made in my letter to you, which certainly you were, and are at perfect liberty to publish.

JUSTUS LIEBIG.

Munich, 12th September, 1852."

Just published, 8vo, pp. 96, price 2s. 6d.,

**A TREATISE ON CATARACT;**

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F.R.C.S.,

Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5s.,

**THE INFLAMMATIONS OF THE EYEBALL:**  
Being a Treatise on all the Species and Varieties of Iritis.

Dublin: Fannin and Co., 41, Grafton-street, or the Office of the MEDICAL PRESS, 15, Molesworth-street. London: John Churchill, Princes-street, Soho.

**THE REVERSED AND DOUBLE-ACTIONED PATENT TRUSS.**

Invented by FRANCIS L'ESTRANGE, Esq., F.R.C.S.I.

WILLIAM DUFF, of 37, Molesworth-street, Dublin, calls the attention of the Medical Profession and the Public to this Truss. He can state with confidence it is the only instrument constructed on Scientific Principles, having for its object the Radical Cure of Rupture. It acts not merely as a palliative, but will produce a radical cure, as is attested by numerous certificates.

W. D. is the only Manufacturer of the Instrument. The trade and public institutions will be liberally dealt with.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Cozeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

**THE COMPOUNDING DEPARTMENT AT G. O. AND CO.'S MEDICAL ESTABLISHMENT**

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

**BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.**

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

 Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

**ROYAL COLLEGE OF SURGEONS IN IRELAND.****SCHOOL OF SURGERY.**

WINTER SESSION 1852-53.

The Dissecting-rooms opened on the 1st of October, and the Lectures will commence on the 25th.

Anatomy and Physiology—Dr. Jacob.  
 Descriptive Anatomy—Dr. Hart and Dr. Power.  
 Surgery—Mr. Porter and Mr. Hargrave.  
 Practice of Medicine—Dr. Benson.  
 Chemistry—Dr. Barker.  
 Midwifery—Dr. Beatty.  
 Comparative Anatomy—Dr. Jacob.  
 Dissections by the Professors of Anatomy and the Demonstrators—Dr. Leeson, Mr. T. D. Hargrave, Mr. Malcomson, and Mr. J. Morgan.

**SUMMER SESSION.**

Materia Medica—Mr. Williams.  
 Botany—Dr. A. Mitchell.  
 Medical Jurisprudence—Dr. Geoghegan.  
 Practical Chemistry—Dr. Barker.

The Fee for each of the above Courses is Two Guineas.

For further information apply to any of the Professors, or to the Registrar.

By order,

W. BOYLAN, Registrar.

**CITY OF DUBLIN HOSPITAL.**

The Winter Course of Practical, Medical, and Surgical Instruction commenced on the 1st of October.

The Clinical Lectures will be delivered by Dr. Jacob, Dr. Benson, Dr. Beatty, Mr. Hargrave, Mr. Williams, Dr. Geoghegan, and Mr. Tufnell.

Dr. Jacob will deliver a full Course of Lectures on Diseases of the Eye; Dr. Beatty, select Lectures on Diseases peculiar to Women and Children; and Mr. Tufnell on Military Surgery.

Sir Henry Marsh, Sir Philip Crampton, Professor Porter, Mr. Cusack, and Dr. Apjohn, give their assistance in cases requiring consultation.

Certificates of attendance are received as qualification by all the Colleges, Halls, and Boards.

**DISEASES OF THE EYE.**

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

**THE MIDLAND RETREAT,**

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY.)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System.

Under the direction of Dr. JACOB, Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

**QUEEN'S COLLEGE, BELFAST.**

SESSION 1852-53.

**FACULTY OF MEDICINE.**

The Session will commence on Tuesday, October 19, 1852. The Matriculation Examination will begin on Friday, the 22nd of October.

Six Scholarships, of the value of £20 each, will be awarded by Examination at the commencement of the Session. Scholars are exempted from payment of one-half of the class fees in their department.

Two Senior Scholarships, of the value of £40 each, will be awarded by Examination at the commencement of the Session to Students who shall have completed the course of study of the first, second, and third year prescribed to Candidates for the Degree of M.D.

For the times and subjects of the several examinations, the courses of study, and other particulars, including full information as to the method of proceeding to the Degree of M.D. in the Queen's University in Ireland, see "Belfast Queen's College Calendar" for 1852.

By order of the President,

W. J. C. ALLEN, Registrar.

Queen's College, Belfast, June, 1852.

**MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY.**

The Winter Session commenced on the 1st of October. The usual courses of Clinical Instruction will commence on the first Monday in November, and will be continued through the session by the Physicians and Surgeons of the Institution.

Arrangements have been made to prevent the hours of attendance and lectures from interfering with any other place of instruction in Dublin.

The Medical and Surgical Clinical Instruction will be carried on on the alternate days—Mondays, Wednesdays, and Fridays for SURGICAL; and Tuesdays, Thursdays, and Saturdays for MEDICAL Instruction.

Operations, unless in cases of emergency, will only be performed on the days of surgical instruction.

A Surgical Registry of all cases admitted into the hospital is carefully preserved, and is open to the inspection of the pupils. A dispensary is attached to the hospital, in which the pupils are allowed to perform all the minor operations in surgery, under the guidance of the attending surgeons. From 200 to 300 patients are prescribed for and relieved in the dispensary daily.

The following premiums are to be awarded, as usual, at the close of the session:—

1. The Clinical Medical Premiums.
2. The Clinical Surgical Premiums.

Of these there are two in each class to be awarded according to the order of merit.

The situation of Resident Pupil is open to pupils as well as apprentices of the hospital.

Special recommendatory certificates are given to such gentlemen as have filled the situation of Clinical Practising Assistants in the hospital for at least four months to the satisfaction of the medical officers.

Certificates of attendance on this hospital are acknowledged by all the Colleges, Halls, and Boards.

The Medical Clinical Instruction is given by Dr. Stokes, Regius Professor of the Theory and Practice of Physic, Trinity College, Dublin, &c.; and Dr. Lees, Fellow of the College of Physicians, Lecturer on the Practice of Physic, Examiner in Medicine to the Queen's University in Ireland, &c.

The Surgical, by Sir Philip Crampton; Mr. Porter, A.M., Professor of Surgery, Royal College of Surgeons, Ireland, &c.; Mr. Smyly, A.M., F.R.C.S.I., &c.; Mr. G. Porter, A.M., F.R.C.S.I., &c.; Mr. Collis, A.M., F.R.C.S.I., &c.; and Mr. Rynd, A.M., F.R.C.S.I., &c. &c.

For further particulars apply to Francis Rynd, Secretary, No. 19, Ely-place, or at the hospital.

**TERMS OF SUBSCRIPTION (PAYABLE IN ADVANCE).**

### DISLOCATION OF THE HUMERUS FORWARDS AND UPWARDS—MODE OF REDUCTION— AUTHORITIES AS TO THE POSITION OF THE LIMB.

By RICHARD G. H. BUTCHER, F.R.C.S.I.,  
Examiner on Anatomy and Physiology in the Royal College  
of Surgeons in Ireland,  
Surgeon to Mercer's Hospital,  
&c. &c. &c.

THE following well-marked case of dislocation of the hu-  
merus forwards recently came into hospital, presenting  
characters, striking and conclusive, on the disputed point,  
as to the shortening or lengthening of the limb in this dis-  
placement. I consider it stamped with sufficient import-  
ance to demand a few observations:—

Eliza McMahon, aged 35, a large muscular woman, was  
admitted into Mercer's Hospital at eight a.m. October 3,  
1852, under my care. On the evening previous to her  
admission, at eleven o'clock, she was disorderly in the  
street, and being taken up by the police, she offered great  
resistance against being taken to the station-house. In  
the struggle that ensued, she says she remembers having got  
a very violent twist in the right arm, which gave her the  
most excruciating pain. She was retained all night as a  
prisoner, and brought on the following morning, at the time  
specified, to the hospital, nine hours having elapsed from  
the period of the receipt of injury.

On stripping the chest and shoulders, the deviation from  
symmetry was marked and striking. Circumstances com-  
bined to render the outlines of the injury prominent—viz.,  
a few hours had only passed from the moment she sus-  
tained the accident; therefore, effusion had not time to  
set in and round off the irregularities created by the new  
position of parts. Again, the patient, though large and  
full, had the muscular system well developed, with scarcely  
any deposit of fat.

The most prominent features of the accident were the  
following:—There was flattening of the shoulder and pro-  
minence of the acromion far greater than in the dislocation

into the axilla. The deltoid was not only flattened and  
flaccid, but likewise twisted forwards, the fibres attached  
to the posterior edge of the acromion participating most in  
this puckering of the muscle. The head of the bone formed  
a remarkable tumour to the sternal side of the coracoid  
process, corresponding to the centre of the clavicle, and  
about half an inch below its inferior edge; so prominent  
was the swelling, that the coracoid process could very in-  
distinctly be felt as it lay buried external to it. The axis  
of the shaft of the humerus was directed from this point,  
about the centre of the clavicle, slightly backwards; at  
the same time, it lay close to the side—a position quite  
contrary to the descriptions given by writers on the sub-  
ject. In another instance where I was consulted very  
recently, the limb also hung close to the side, and its other  
characteristics were as marked as in the present instance.  
*The amount of shortening, measured with the greatest accu-  
racy, was more than half, and very nearly three-quarters of  
an inch.* Now, this fact was verified by the observation  
and measurement of others as well as myself. All the  
movements of the joint were greatly restrained. Any  
attempt at bringing the limb forwards was productive of  
great pain, and at once interrupted by the head of the bone  
being tilted against the coracoid process. Backward, mo-  
tion was restrained by the action of muscles, and the carry-  
ing of the limb outwards was prevented by the opposition  
of the clavicle to the head of the bone.

I readily reduced the dislocation in the following way:  
Having placed the patient on the side of the bed in which  
she had been lying, in the sitting posture, a folded sheet  
was passed round the chest, close under the injured part,  
and the ends given to an assistant who stood at the op-  
posite side of the bed; thus counter-extension was provided  
for. Standing on the right side of the patient, with my  
left foot resting on the edge of the bedstead, I brought the  
luxated arm over my knee, and made forcible extension  
downwards by means of a jack-towel previously fastened  
and secured by the clove hitch round the humerus at its  
lower end: thus, the head of the bone was moved down-  
wards below the coracoid process. The extending force

was then directed outwards, and a little forwards, by the aid of an assistant, and the head of the bone was quickly drawn up to the glenoid cavity, and restored with an audible snap. By placing the patient on the side of the bed, instead of on a low chair, as is usually done, I gained great additional power by bringing into acquisition the weight of my body and shoulder in forcing down the extending band in the manner described.

After the reduction was effected, the limb was bandaged to the side, and the elbow supported, by a sling tied over the opposite shoulder. Surgical authorities are somewhat divided as to whether the arm be shortened or lengthened in the dislocation of the humerus forwards. In the cases which I have seen, and as noticed in the one just mentioned, the shortening amounted to *more than half, and nearly three-quarters of an inch*. According to Sir Astley Cooper, too, the arm will be shortened, and though by a reference to the cases which he details in his work, there is no allusion to this symptom, yet it is clear that from what he observed in those cases, he arrived at the above conclusion. On the other hand, Desault and Malgaigne maintained there would be elongation; and Dupuytren, though at first discountencing this opinion, yet from some experiments which he instituted after dissecting the ligament in a recent joint, and producing dislocation, he found lengthening to half an inch. Now, I contend that a careful analysis of the experiments instituted by Dupuytren and Malgaigne on this point will prove them to be imperfect, faulty, and incapable of establishing the premises sought to be laid down. Dupuytren writes:—"It was my impression that, when lengthening existed, it could only be attributed to dislocation *downwards* beneath the glenoid cavity; but M. Malgaigne was of opinion that, as the head of the humerus occupied the concavity of an arch formed by the acromion, the coracoid process and the ligament which connects them, it should evidently be at a lower level when forced beneath either pier of this arch: we therefore determined on having recourse to an experiment to decide the question. In the dry bones, it was clear that dislocation under the acromion involved lengthening of the arm; but it remained doubtful whether this was the case in displacement beneath the coracoid process. The latter dislocation was produced in an arm recently prepared for the purpose with the ligaments attached; and by carefully comparing the measurements before and after the experiments, it was proved that elongation to the extent of about half an inch was the result." The fallacy of the foregoing observations in reference to the point under dispute is, I think, apparent for the following reasons. Having frequently tried myself to dislocate the head of the bone in the dead subject, I have failed to produce the displacement I desired. The force cannot be measured with that accuracy, or the same direction given to the bone as takes place by accident; and this very fact is proved by the experiments made by Dupuytren and Malgaigne, who write: "A further experiment was made on the ~~same~~ joint, having reference to the ~~downward~~ dislocation. When all the muscles were stripped off, it was still found impracticable to dislocate the bone in this direction, so long as the ligamentous fibres connecting the coracoid process and capsule (coraco-humeral ligament) retained their integrity; but when they were divided, it was easily accomplished." The next sentence which Dupuytren writes, shows that he, too, doubted the accuracy of these experiments as applicable to the living body, for he says:—"It may be naturally asked

are these results identical with those which are usually observed in the living?" He goes still further, for he absolutely invalidates the truth of the experiments altogether; for in speaking of the dislocation downwards, he writes: "The most remarkable point about the latter experiment is, that the amount of lengthening exceeds *an inch and a half*, which is far more than ever existed in any authenticated instance." I deny altogether the head of the bone in the dislocation forwards being in the position ascribed to it by Dupuytren and Malgaigne. No doubt if it rested "beneath the coracoid process," the internal pier of the arch, which they assert from their experiment, the limb must be slightly lengthened; but Dupuytren, when he writes, "are these results identical with those which are usually observed in the living?" likewise says, "the solution of this question can only be found in the dissection of suitable cases." Suitable cases have occurred of recent dislocation, and where dissection proved the inaccuracy of the experiments and the erroneous conclusions of these investigators.

In the third volume of the *Dublin Journal of Medical Science*, there is a case of undoubted primary dislocation, recorded by Sir Philip Crampton, which is interesting, not only as setting at rest the long-disputed question as to the possibility of its being primary, but also as being the first recorded dissection of the parts in an example of recent dislocation forwards. The head of the humerus was lodged on the inner side of the neck of the scapula to the *sternal side of the root of the coracoid process*, and extending up nearly as far as the notch in the superior costa. The capsular ligament was perfectly entire in the direction of the axilla, showing that the bone could not have been sent first to the axilla and afterwards to the situation here described. The opening in the capsular ligament was on its inner side, and was caused by its being torn from the glenoid cavity, the rent extending from the supra-spinatus muscle above to the under part of the subscapularis muscle below. The supra and infra-spinati were much on the stretch, but not lacerated, and the subscapular muscle was partly detached from the upper and the anterior parts of the subscapular fossa, and passed downwards, so that its fibres in a curved manner embraced the neck of the bone. The axis of the bone was scarcely a quarter of an inch above the centre of the glenoid cavity, and the vessels and nerves were on the sternal side of the tumour. Mr. Key made a dissection of a shoulder which had been long dislocated inwards. The glenoid cavity was completely filled up by ligamentous matter, and the head of the humerus was situated under the clavicle to the *sternal side of the root of the coracoid process*, in contact with the venter of the scapula, from which the subscapularis muscle at that part was torn off, and separated from the ribs by that muscle and the serratus magnus muscle.

In addition to these dissections, which establish the position of the head of the bone as being *internal to the coracoid process*, and the limb shortened, I may adduce the following authorities:—"In the luxation forwards, the limb appears somewhat shortened."—*Liston*.—"The arm has either its natural length, or is rather shorter."—*Chelius*.—"The head of the bone is displaced to the inside of the coracoid process, and is locked between that and the clavicle; the arm is somewhat shortened."—*Miller*.—"The limb is shortened." (See Plate in "Fergusson's Practical Surgery.")

It is strange that Mr. Bransby Cooper "never saw a dislocation where the head of the bone was thrown upon the inner side of the coracoid process." He states in the dislocation forwards, the head of the bone "is thrown *beneath* the coracoid process of the scapula." This certainly is not the position of it, and he contradicts himself, for he adds, "under common circumstances, the shortening of the limb is so slight as to be scarcely appreciable." Now, if the head of the bone be where he states, beneath the coracoid process, the limb must be lengthened, as proved by Malgaigne.

## OBSERVATIONS ON THE IMPULSE OF THE HEART.

By ROBERT CARTWRIGHT, Esq.

THE cause of the impulse and sounds of the heart still lies in the greatest obscurity; each successive writer brings forward, like an advocate defending a bad case, an ingenious and fine-spun theory, merely to be torn in pieces by his successor. This extraordinary discrepancy appears to the author to proceed from the fundamental error, that the impulse occurs during the systole; and the difficulty can, in his opinion, only be solved by returning to the theory formerly advocated by Drs. Corrigan and Stokes.

The theory that the impulse takes place during the contraction of the ventricles rests entirely on vivisections and experiments on dead hearts; Mr. Cartwright is not aware that a single physiological reason has been advanced in favour of it. All those experiments led to the following conclusion, "that the heart during its contraction is elongated, and strikes against the chest by raising the apex;" but latterly it is generally agreed, that the heart during its contraction is shortened (a fact the author knew twenty years ago), and that the appearances in those experiments were misunderstood and incorrectly explained; consequently, the author observes, if the conclusion drawn from those experiments is erroneous, the theory based on that erroneous conclusion naturally falls to the ground. The latest theory is Dr. Kiwisch's, "that the impulse is caused by the swelling of the muscular substance of the heart during its contraction;" but this explanation the author says is untenable, as the external layers of muscular fibres are spiral and not longitudinal; consequently, their contraction being concentric, simply diminishes the cavity of the heart without any swelling or external elevation, as in the muscles of the extremities. But granting that there is an external swelling, the diminution at the same time in the circumference will prevent any nearer approximation to the surface of the chest; and granting, again, that an impulse were produced by such a swelling of the muscular substance, it would occur in the third or fourth, and not in the fifth intercostal space.

In 1830, being then a student in Dublin, Mr. Cartwright heard of Dr. Corrigan's theory, that the impulse occurs during the diastole. On returning home, he opened a rabbit, and not wishing to cause the animal unnecessary pain, he gave it a gentle rap on the head, sufficient to cause a depression of the bone. On opening the chest, he saw the heart beating quietly and regularly; after about half a minute it became agitated, and during these agitated movements the heart appeared to be elongated, and its apex to be turned upwards, at the same time giving a kick, as it were, an expression much in favour with lecturers on anatomy some twenty years ago. After about a minute, the action of the heart became quieter, and the last movements resembled the first. A month ago he examined two rabbits under the influence of chloroform; no irregular or spasmodic action occurred in either case; the heart appeared to dilate and contract in its natural manner. During its contraction, the heart was evidently shortened and narrowed; that is, less in circumference; the apex was somewhat flattened, and appeared once to be actually drawn inwards; but during the diastole the apex shot out again with some force. These appearances are in perfect harmony with the anatomy of the muscular substance of the heart; the muscular substance of the left ventricle, for instance, may be to a considerable extent separated into two layers—an internal, consisting of longitudinal fibres, running from the apex towards the basis, and an external, consisting of a network of fibres, running principally in a spiral direction. The contraction of the longitudinal fibres shortens the heart, and their consequent swelling fills up the space previously occupied by the blood driven out by their contraction; at the same time the spiral or circular fibres, by their contraction, force out a certain quantity of blood, and press in relative proportion the internal surfaces towards one another, so that a contracted heart is shorter and less in circumference

than a heart dilated and full of blood; and as the heart lies in a sloping direction from above downwards and forwards, and with a part of its surface in close apposition to the inner surface of the chest, the author concludes that the impulse occurs during the diastole, when the heart is increased not only in length, but also in circumference, and consequently presses closer to the inner surface of the chest than it does during the systole.

The following case, about a child a few days old, and in which the sternum was deficient, is reported by Dr. Skoda: "By applying the hand, one could easily perceive that the heart was vertically placed, and moved with each systole downwards and forwards, with each diastole upwards and backwards. The impulse was felt with each systole of the heart, immediately above the insertion of the diaphragm; with each diastole, on the contrary, as high as the second rib, if the fingers were sunk sufficiently deep towards the spinal column. The impulse of the diastole was just as strong as the impulse of the systole. On placing two fingers in such a manner, so that with the systole the lower, with the diastole the upper, finger felt the impulse, it was found that the heart, during each systole, glided about an inch downwards." There can be no doubt that Dr. Skoda has here made a slight mistake between systole and diastole. It is quite past the author's comprehension how a heart during its contraction could move downwards and forwards, and during its dilatation, upwards and backwards; and how the impulse of the heart, shortened by its contraction, could be felt immediately above the insertion of the diaphragm; and during its dilatation, when it is not only increased in circumference but also in length, an impulse should be felt nearly under the second rib, and then only by sinking the finger sufficiently deep towards the spinal column. It would almost seem that Dr. Skoda had recorded this case in anticipation, as a refutation of Dr. Riviset's theory, and as a proof of the diastolic theory. Dr. Albers, in his work, principally compiled from Davies's Lectures, states that the heart must elongate itself several lines, so as to produce the impulse in the fifth intercostal space. Mr. Cartwright believes that the ventricle acts as a sucking-pump, and sucks the blood in; its dilatation being quite independent of the contraction of the auricle, which is proved by the following experiment:—He cut the auricle through, the blood flowed into the chest, and the ventricle dilated several times afterwards. The heart also pulsates after it is cut out and placed on the table. This active dilatation of the ventricle is caused by the elasticity or tone of the muscular fibres. What he understands by the elasticity or tone of the muscular fibres is the power by which they return to their natural position; thus if a muscle is stretched by an abscess underneath it, or by any other cause, on removing the cause the muscle immediately returns to its natural position. This act is not contraction in its usual meaning. Also when a muscle, be it a voluntary or involuntary one, contracts, this occurs through the agency of a higher power; and when this power ceases to act, the fibres of the muscle do not remain relaxed in the same identical position, but return with a certain degree of force to their natural position. This is apparent in the biceps humeri, but still more so in the vastus internus and the gastrocnemii. This action—namely, the muscle returning to its natural position from a state of contraction or extension—depends on a principle resident in the fibres themselves, call it elasticity, tone, or by any other name; and it is through this principle that the dilatation of the heart takes place.

The semilunar valves are never pressed against the sides of the artery, otherwise they would be retained in that position by the continuous stream of blood; and it also appears to the author, from observations on the hearts of animals in a state of spasmodic contraction after death, that certainly not more than half of its blood is expelled out of the left ventricle during each systole. With reference to the sounds of the heart, he states that the first is heard most distinctly at the apex; it appears to come towards the ear; whilst the second is acknowledged to arise at the semilunar valves, and to be carried along the

aorta. This harmonises completely with the diastolic theory; while the first sound is caused by the passage of the blood through the auriculo-ventricular opening and the valve towards the apex; and the second sound is caused by the forcible pulsation of the blood through the semilunar valves. The bruits in diseases of the heart are also more naturally and correctly explained by this theory, as may be proved by an analysis of the various treatises on auscultation, especially the admirable treatise by Dr. Skoda (4th edition, 1850, Vienna), a work to one can read without feeling the highest esteem for the candour and logical acumen of the learned professor. But it is not necessary to make vivisections or experiments on dead hearts; every man carries in his own breast evidence sufficient to prove that the impulse occurs during the diastole. The author has himself made the following experiment several times:—If a person lies in bed, on the left side, and listens attentively, he can hear the second sound most distinctly; should his heart palpitate, or beat somewhat violently, he will feel at the same time, synchronous with the second sound, a shock or concussion in the chest, extending even to the carotid arteries.

Mr. Cartwright remarks further, that each contraction of the ventricles causes one pulsation throughout the arterial system, before another contraction takes place; and as the arteries are elastic tubes, a certain interval or space of time, be it more or less, elapses before the pulsatory wave, caused by the contraction of the left ventricle, reaches the extremities of the arterial system. The carotid artery, just before its bifurcation, may be considered as a middle point between the heart and the capillaries in the brain; consequently the pulse at that point ought to be intermediate between two contractions of the ventricle; and if the impulse of the heart is caused by its dilatation, it ought also to occur in the interval between two contractions of the ventricle; now the impulse of the heart and the pulse of the carotid are synchronous. This explanation also accounts for the impulse not being synchronous with, but immediately preceding, the pulse at the ankle. Mr. Cartwright concludes, therefore, that the impulse of the heart takes place during the diastole.—*Ranking's Abstract.*

### CHLOROFORM AS AN EMMENAGOGUE.

By Dr. Gibson, of Fort Towson, Choctaw Nation, U.S. HAVING nowhere seen, in the course of my professional reading, any allusions made to the use of chloroform as an emmenagogue, I am induced to submit the following facts, partly from a desire that relief may be afforded to the suffering, and partly from a sense of professional duty.

Cases 1 and 2, occurring in the same person. In October last, Mrs. W., having a violent headache, to obtain relief resorted to the inhalation of chloroform. Within an hour after the inhalation (which was but for a few seconds) she was flowing freely, and continued thus for four days. There was no irregularity of the function of menstruation in the succeeding month (November), but another attack of headache supervening, she again had recourse to the chloroform, and in a half hour the menstrual secretion made its appearance, the discharge continuing for five days. In both instances, the chloroform was inhaled about ten days after the subsidence of her regular periods. Since the last inhalation, she has menstruated at her usual period. Mrs. W. is slightly inclined to plethora, general health usually good, aged 35.

Case 3. In the absence of Mrs. W. from home, her servant girl, having gotten hold of the chloroform, imitated Mrs. W.'s example. A like result was produced upon the girl, who menstruated for four days. The girl is very healthy, and about thirty years of age. The inhalation was never renewed by her. In this case, the chloroform was inhaled two weeks prior to her usual period, at which time she again menstruated, and has since continued regular.

Case 4. Miss —, aged 19, general health excellent, no deviation having ever taken place since her first menstrual period, was, during a visit to Mrs. —, induced to inhale chloroform, through curiosity, to experience the sensations produced by it. In a half hour the menstrual fluid

made its appearance, and the flow continued for four days. The inhalation in this instance was ten days antecedent to the regular period, with which it did not interfere. Mrs. W., my informant in regard to the foregoing cases, is an intelligent and reliable lady.

Case 5 came under my immediate observation. Was called to see Mrs. H., found her suffering much from suppressed menstruation. To relieve urgent pain, ordered hot hip-bath, from which the patient experienced much relief. Waited three hours after the use of the bath, without recourse to any other means, having decided, as this was an opportune case, to exhibit the chloroform, which was done for thirty seconds. In twenty minutes after its administration, the patient was flowing freely, and continued to do so for three days. Patient is of a weakly constitution, the result of much hardship. Age of the patient, about 40. This case is the more remarkable from the fact that the patient has not menstruated for more than eight months.

The suppression was induced by causes not deemed necessary to relate at present. Prior to the suppression, she had been very regular for many years. Pregnancy has nothing to do with the case, as the patient is not at this time, nor for many years past, has she been in that condition.

I regret that I have not a greater number of cases to submit for the consideration of the profession. Being but a young practitioner, I am desirous that more experienced physicians should give the chloroform a trial, in order more fully, than my position will allow, to test its value as an emmenagogue; and diffident of my ability to account correctly for the *modus operandi* of the chloroform in the above cases, I shall without comment submit them to those who have better opportunities for investigation.

Before closing, however, I will present the following case. Miss —, aged 18, had an acute suppression of the menses, upon the first recurrence of the monthly period, subsequent to the age of puberty. Epileptic spasms quickly succeeded the suppression. Three years have elapsed since, and she is yet subject to these spasms, at longer or shorter intervals. Within the last eight months, she was placed under my care. At one time she will menstruate healthily—at another, there will not be the slightest appearance of menstruation—again, a leucorrhœa will take the place of the proper menstrual fluid. Sometimes, the leucorrhœa, as also the menstrual discharge, whichever it may be, will appear a week, sometimes two weeks antecedent to the regular period. Without entering into detail, as regards the treatment adopted in this case, I will submit the subjoined query. Upon the hypothesis, that the chloroform did act as an emmenagogue in the cases already related, how far would it comport with the safety of this epileptic patient to administer the chloroform? This question is predicated upon the belief, that, if the menstrual function were regularly performed, recovery from the epilepsy might take place. It is intended that the question shall refer more particularly to the epileptic condition, than to the irregularity of the menstrual function. I have no reason to suppose the existence of organic disease, either of the brain or uterus, in this patient.—*Phil. Med. Examiner.*

### RUPTURE OF THE TENDO-ACHILLIS.

J. H.—, labourer, aged 48, of intemperate habits, while walking, in November last, across a bridge, stepped upon the edge of a hole with his right foot, letting the heel drop into it, and making a sudden effort to recover himself, he felt a sharp pain extending from the heel up the leg, accompanied by an audible snap. In attempting to go a few steps farther he felt the same again, which rendered him unable to walk. He was brought home, and on examination the tendo-Achillis was found entirely separated about two inches above its insertion. The divided extremities were nearly an inch apart, as plainly to be felt as after a subcutaneous section for club-foot. He has been unable to walk without a crutch or cane until within the last month, but at the date of this the union seems to be pretty firm, and he walks pretty well by favouring it a little.—*Dr. Barrett in Buffalo Med. Jour.*

## TREATMENT OF THE DUKE.

A very old gentleman, somewhat beyond four-score years, feels unwell very early in the morning, and sends for his surgeon-apothecary, who on his arrival prescribes tea and toast, and leaves his aged patient to his fate. Soon after, the surgeon-apothecary is recalled, when, on his return, he finds his patient alarmingly ill, with incipient epilepsy, and for the first time considers his case; when he fixes, as its cause, on some venison eaten the day before. Now, query, if the patient's then condition proceeded from undigested venison, was the further cramming with tea and toast judicious, or a common-sense proceeding?

Again, was an emetic at all admissible in a subject of such an extended age? A mustard emetic, it is true, was only administered, which is considered (because generally at hand) an "innocent dose;" but let some of those who are so fond of prescribing the innocent dose, make a trial of one, and they will understand its powerful effects. Innocent, indeed! How many unhappy children have I seen sent flying to a premature grave by this domestic and innocent dose.

In very old people it is a very common circumstance for irritating gas to be secreted and to be pent up in the stomach and bowels, frequently exploding on the sensorium, and causing what are called fits, with sometimes intolerable pain and anguish; but which may be easily remedied by some of the various carminative doses in general use. I recollect having been once hurriedly sent for to visit an old lady of 72, suffering from great agony, and which the two "cognoscenti" medicos, whom I found in attendance, considered to be pleuro-peritonitis, and had the old lady's arm tucked up, ready for bleeding. I recommended a carminative draught, in which there was ol. ruta. The effect was, apparently, miraculous; an explosion equal to the cannonading of a ten-gun battery was the consequence of the draught, with immediate relief, and a total disappearance of the pleuro-peritonitis. Further, is it usual to place a person in the erect position, bolt upright, with fits of any kind? I am aware that slight elevation of the head is usual.

I notice, in the periodicals of the day, comparisons made between the career of Napoleon and the late Duke, which I think may not be irrelevant to my queries, but that some similarity, by some of your numerous correspondents, may be discovered as to the exit from this sublunary sphere of the two heroes in question, although neither were killed on the battle field. A word at parting, as a last query.—Should not much caution be exercised as respects vomiting, even with mustard, and bleeding octogenarians?—*Med. Circular.*

## INSTRUMENT FOR CAUTERIZING THE URETHRA.

By Dr. COOPER of Peoria, Illinois, U.S.

An instrument for cauterizing the urethra has been invented by Dr. Cooper of this place; which, for facility of application and certainty of results, is superior to all other means hitherto used combined.

It consists of a copper catheter, with the end for half an inch a little smaller than the body, and perforated with several holes. This is introduced down to the stricture, and then filled with dilute nitric acid, which, acting on the copper, soon produces the nitrate, which, coming in contact with the urethra through the holes, produces cauterization to the extent desired.

The strength of the solution and the length of time the instrument is permitted to remain, regulates the degree of cauterization completely. Dr. Cooper generally uses one-third of nitric acid, and two of water, and permits the instrument to remain for one and a half minutes, though a much shorter time will often answer.

The shape of the instrument may be varied to suit the case; thus, when several strictures exist in the strait part of the urethra, a strait catheter might be used, with holes at several places to correspond to their number and location.

Though great contrariety of opinion exists among medical

men in regard to the degree of cauterization most valuable, this instrument commends itself alike to all; for whether it is believed that caustics should be applied boldly, so as to cause the detachment of a slough, and thus physically enlarge the canal, or by a slighter application modify the action of the lining, the variations are easily made with it. —*Phil. Med. Examiner.*

## DISLOCATION OF FEMUR LEFT UNREDUCED.

It is probably no very uncommon event for a dislocated hip to be left unreduced, even where the case has been under the hands of a clever surgeon, but it is certainly not often that such cases obtain a public record. We are not over-zealous generally to publish our own failures, and it is hardly generous to advertise the failures of others; so that between our selfishness and our unselfishness many of the shortcomings of our art are hidden. Fortunately, Mr. Chelius, the author of a most excellent "System of Surgery," has sufficient reputation the world over to enable him to bear a portion of these failures, without injury to himself or the profession, which he so eminently illustrates. I shall therefore make no apology for requesting you to record this unsuccessful attempt to reduce a dislocated hip, in which he was himself the operator. June 11, 1851: J. Maurer, a German, aged 19, called upon me, and related as follows: "When ten years old I fell from a tree, a height of six feet, and dislocated my left hip. I was then living twelve miles from Heidelberg, and was immediately taken there, but I did not see Mr. Chelius until the next day. He took me to the University, and, before the medical students, attempted to reduce it, but he could not. During several weeks following he tried six times, using pulleys, &c., but he never could succeed." I find the limb shortened two inches; the knee is turned in, and the toes out. The dislocation is upward and backward upon the dorsum ilii. He walks rapidly and without pain or discomfort, but with a manifest halt.—*Mr. F. H. Hamilton in Buffalo Med. Jr.*

## REVIEWS AND NOTICES OF BOOKS.

NEURALGIA, its Various Forms, Pathology, and Treatment. Being the Jacksonian Prize Essay of the Royal College of Surgeons for 1850, with some Additions. By C. T. DOWNING, M.D., M.R.C.S. London. 8vo. pp. 375.

We have had this book, with others, on our table for some time waiting for notice, but not forgotten. We often, perhaps, postpone such duty until authors begin to think that we have neglected them altogether; but we are of opinion that a review comes in very good time when the novelty of the publication has a little worn off, and when our contemporaries have exhausted all their critical powers on them.

As the title states, this is an amplification of a prize essay, embracing some points not previously noticed, and suggesting a new plan of treatment in certain cases. The subject is one of the highest importance to the practitioner, not merely as affording information respecting the nature and treatment of a most distressing disease, but as furnishing materials for the elucidation of obscure symptoms often considered inflammatory. We cannot better explain to our readers the object of the work than by selecting a few extracts, comprising some of the most important inquiries and suggestions. On the remedies for neuralgia we have the following chapter:—

"One of the most prominent of the internal remedies, generally employed in the treatment of neuralgia, is the sesquicarbonate, or carbonate of iron. This medicine was introduced to notice by Mr. Hutchinson of Southwell. In the second edition of his work, published in 1822,\* many cases are recorded of its successful administration; but, as has been acutely remarked, those of failure are not alluded to. At first, the greatest hopes were entertained that this preparation of steel was a real specific for the tic douloureux. Experience has shown, however, that it cannot be depended on,

\* Hutchinson on Tic Douloureux.

Sometimes it has been eminently successful; at others, quite useless.

Dr. Elliotson, who is a great advocate of this mineral, says of it:—"Although it is the best medicine at present known under these circumstances (neuralgia), it frequently fails altogether; and still more frequently the disease returns, but perhaps yields again and again to it." The cases which this gentleman has detailed in the *Medico-Chirurgical Transactions*, afford, perhaps, the most direct and decided evidence of the power of iron over this disease. They are much better than those of the original discoverer, for in several instances Mr. Hutchinson employed active agents at the same time. *Levi Vallerius* has shrewdly remarked this, for he says, "But in estimating the value of the remedy, there is another point that deserves consideration. Was the subcarbonate of iron the only agent employed? In five of the cases that I have taken from Hutchinson, the treatment was complicated; and the remedies employed with the salt of iron were by no means powerless agents, as we shall see. Two patients were rubbed with tartar-emetic ointment, until a crop of pustules arose on the surface; two others took the datuara stramonium with great regularity during a considerable period of their affliction; with the fifth, pills of calomel, antimony and opium, were given night and morning, in addition to belladonna and other narcotics; in a sixth case, it is not stated whether the iron was used alone or combined with other remedies. It is therefore very difficult to determine what effects were produced by the subcarbonate. In one case only could the cure be distinctly traced to its employment. In this instance all the other remedies which had been tried and found useless were suspended, and the amelioration commenced directly the steel was administered by itself. Mr. Hutchinson himself, in his postscript, candidly admits that he never trusted to his favourite preparation alone."

That the sesquicarbonate of iron will not always cure neuralgia the most ample testimony is afforded. I will venture to assert, that in every one of the chronic, reported-incurable cases now existing in this country, this favourite remedy has been repeatedly tried. Many of my patients have told me that they have swallowed very great quantities of 'rust-iron,' as they call it, sometimes with a little, often with no benefit. Sir H. Hallford mentions the case of a lady, who took, during the course of her illness, twenty-seven pounds of the carbonate, and yet died the victim of neuralgia.

Notwithstanding these drawbacks, I consider it a valuable remedy. When the patient is not plethoric, and has no tendency to determination of blood to the head, it should always be tried. It is most likely to be serviceable when the disease is associated with debility and anæmia. If the patient have a weak small pulse, with coldness and paleness of the surface, the happiest effects may be expected from its employment. In moderate doses it tends to improve the general health; in larger quantities it is a tonic to the nervous system, allaying, in a specific manner, that excitability on which the neuralgic paroxysm depends. If it disagrees with the stomach, or produces restlessness and fever, it should be discontinued, as itself a sufficient exciting cause of the malady.

Great care should be taken in the selection of the medicine, as there is a great difference in the quality of various samples. The best preparation is the precipitated sesquicarbonate, and it should be newly made, otherwise it may have passed into the comparatively inert oxide. That manufactured by Howard I believe to be the best.

It may be given in large and frequently-repeated doses. Mr. Hutchinson gave, it appears, about ninety grains in the twenty-four hours. Dr. Elliotson has since most satisfactorily shown that it may be taken with safety in much larger quantities. In fact, as much may be swallowed as can be borne on the stomach. It will rarely constipate when taken in twice its weight of treacle; and this is therefore the usual vehicle in which it is administered. A smart aperient should be given now and then, to obviate the ill effects that would arise from accumulation of so bulky a material. It should be persevered with for some time.

Other ferruginous compounds may be employed when the carbonate disagrees; the sulphate in full doses, for instance, or the muriated tincture. For persons of delicate stomach, the elegant preparation called citrate of iron may be prescribed. The magnetic oxide has been lately introduced. Where steel is decidedly indicated, I have found it advisable to change the form frequently, in order to ensure its full and permanent effect on the system.

Previous to the trial of this and other tonic remedies, great care should be taken that the cases are suitable—otherwise more harm than good will follow their administration. It is

assumed by most people, that neuralgia is a disease of debility, and that the nerves require strengthening, or bracing as it is called. It was the opinion of Sir Astley Cooper, that they were rather below par than otherwise in this complaint; and therefore required to be brought up to the healthy standard. Yet it cannot be denied that, occasionally, neuralgia is associated with a plethoric condition of the system, and a tendency to determination of blood to the head. Dr. Copland has cited one or two remarkable cases, where the disease seemed to depend upon such congestion, and was cured by general and local bloodletting. Hence it will always be advisable to take precautionary measures, and preface the iron by the application of a few leeches to the head if necessary, or the administration of a brisk purgative. As a general rule, it will be found that these tonic remedies are only serviceable when the tongue is clean, and the mucous membranes in a healthy condition.

*Bark, Quinine, and Arsenic.*—These are medicines that should be classed together, as they act in a similar manner upon the system. They are tonic and antiperiodic. Their power in ague and other intermittent diseases probably suggested their employment in neuralgia, which we know is characterized occasionally by some aguish phenomena. Their value in the treatment of the douloureux is in proportion to its periodicity. When the paroxysms recur at stated fixed intervals—say six o'clock every evening for instance, with an entire absence of pain at other times—they are especially serviceable. They should be tried also whenever the pains are transient, or fly about from one point to another.

With respect to the comparative qualities of these drugs something should be said. The quinine is an elegant preparation, and is well borne by the stomach. It should be given in large doses; two, three, or four grains three times a day. Ten grains administered just before the anticipated accession of a paroxysm, will sometimes cut it short altogether, as it does in ague. It has, I believe, more power over the douloureux in the liquid than in the solid form. In deference, however, to the opinion of Dr. Elliotson, the powder should be tried if the solution fail.

A combination of this drug with a salt of iron will often be found to act most beneficially. A physician of large practice in this metropolis is in the habit, I understand, of prescribing for his neuralgic patients very large quantities of these medicines—ten grains of quinine and five of the sulphate of iron every fourth hour. As such very heroic doses are rarely well borne, I have generally adopted some such formula as the following, in cases of neuralgia attended with debility and an anæmic condition of the system:—

*R Quininae disulphatis, gr. xxiij.*  
*Ferrisulphatis, gr. iij.*  
*Tinct. cinnam. co. ss.*  
*Infus. rosæ, ℥viij.*  
*Misce, fiat mistura.*

The citrate of iron and quinine is an admirable preparation, well adapted to young and delicate females. Sometimes, when quinine has failed altogether, a cure has been effected by the Peruvian bark itself. We know that all the virtues of the latter do not reside in its alkaloid. Some of the best qualities and the full effect of the cinchona are only to be obtained by having recourse to the original drug. It will be well, therefore, in certain cases, to try the powder or decoction. The liquor cinchonæ flavæ of Mr. Battley is a very efficient preparation. In the hands of Mr. Roberts it appears to have been very serviceable. It is useless, however, to persevere in the administration of this or any other form of cinchona beyond a week or ten days together, as the beneficial influence, if at all, is evinced in a very short time.

When the bark and its alkaloid are found to disagree, or fail to relieve the symptoms, a trial may be made of arsenic. Of course great care must be taken that the system be in a fit state for its exhibition.

Some gentlemen have great faith in the virtues of this mineral in neuralgia, as it was the sheet-anchor of Dr. Macculloch. It is said to be especially beneficial in cases arising from malaria, as well as where the disease is very chronic and irregular. A modern writer (Dr. Hunt), who advocates strongly its employment, thus describes its qualities and the cases in which it should be administered:—

"Arsenic operates most favourably on persons who are of lax fibre, accompanied by a languid state of the circulation, and whose secretions are rather profuse than otherwise; the urine pale and plentiful; and more especially on those whose skin is cold and moist. In persons of this description, while arsenic, to an extent far beyond any other medicine, relieves

the neuralgic pain, it improves the general health, and gives firmness and vigour to the constitution. Dr. Hunt recommends that it should be given in full doses, and continued until its effects are felt on the system. As soon as symptoms of poisoning appear it should be discontinued, but not before; as it is then only that its specific effect is manifested. A case that came under my own care a while back will serve to illustrate the mode of administration, and the effects of this powerful auxiliary.

#### Case of Neuralgia treated with Arsenic.

A. H., aged 35, a lumber in the East India Docks, living in the Isle of Dogs, complained, September 13, 1848, of violent pain in the right temple, shooting from thence up to the top of the head, down the neck and to the back of the ear. This had seized him suddenly upon returning home from work one afternoon about a fortnight before. Obligated to give up his employment; could not sleep at night; appetite gone altogether.

Upon inquiry, found that the pain was remittent. It never left him entirely, but came on with increased severity at times about four in the morning, and from six to seven in the evening. The paroxysms returned also at uncertain intervals during the night; the pain not increased by warmth or pressure; teeth sound; tongue clean, but rather white.

Concluded that the *tic douloureux* originated in malaria. so, after regulating the secretions, I prescribed—

September 14th. B Liq. potassæ arsenitis, ʒss.  
Tinct. zingib., ʒj. Misce.

Of this medicine the patient took ten drops, gradually increased to twenty, three times a day, after meals.

21st. The pains have considerably abated, but still are troublesome. Increased the dose to thirty drops.

28th: Patient reports himself perfectly free from pain in the head and face, but complains of a burning sensation at the pit of the stomach, with feverishness; urine scanty and high coloured. As these symptoms were considered to be indicative of the full action of the arsenic, that medicine was discontinued, and ordered to be resumed upon their subsidence.

October 5th: The pains in the head have returned with some severity; they vanished, however, as before, as soon as the system was affected by the mineral.

Two other attacks were similarly treated. By using great care not to push the action of the remedy too far, and by steady perseverance in its use, all symptoms of the disease yielded before the expiration of the month, and did not return.

This is perhaps a favourable instance of the remedial power of arsenic in neuralgia. The effect is by no means always so perfect or permanent. The disease generally returns after the symptoms of poisoning have passed off. An inspection of the recorded cases will show this. Very often it exercises no influence whatever on the neuralgic symptoms. A good illustration of this was furnished a short time since in the case of a baronet, a patient of Mr. E. Wilson, who was suffering severely from frontal *tic douloureux*, although fully under the influence of Fowler's solution for the cure of a skin affection. Arsenic, like quinine, will in some rare cases be found to answer better in the solid than in the liquid form. Care should, of course, be taken that it be properly divided. Dr. Macculloch employed it rubbed up with sugar. The following is a good formula for pills:—

B Arsenici albi, gr. j. Pulv. capsici, gr. v. Ext. gentianæ, gr. v. Misce ut fiant pil. xx.

Of these, one, afterwards two, should be taken three times a day after meals.

Zinc.—A French practitioner named Meglin, some time since published an account of several cases of neuralgia that he had cured by this mineral. I believe that the pills of Meglin still constitute a favourite remedy on the Continent. They are prepared as follows:—

B Ext. hyoscy. nig. Oxydi zinci sublimati an., gr. j. Fiat pil. Sometimes to this is added a grain of extract of valerian.

Meglin began with one pill night and morning, and doubled the dose each day, until there was a sensible amelioration of the symptoms or a derangement of the stomach. In this compound-interest way the Frenchman administered, they say without inconvenience, as many as from thirty-six to forty-eight of his pills in the twenty-four hours, and these large doses were continued for some considerable time. In

this country they find little favour, on account of the supposed inactive nature of one, at least of the ingredients. The oxide is generally superseded by the sulphate of zinc. It is rarely given alone however, but combined with belladonna in the following proportions:—

B Ziñci sulphatis, gr. iss.  
Ext. belladonnæ, gr. ss.  
Ext. anthemidis, gr. ij. Fiat pilula.

This is taken three times a day, and the doses carefully augmented, until either the stomach is affected by the mineral, or the head by the vegetable preparation. It is, I am given to understand, a favourite remedy with some medical men. For my own part, I must confess that I have never succeeded in curing a case of true neuralgia with it alone, although I have found it alleviate the symptoms of several.

The sulphate of zinc is tonic and antiperiodic in its action, and should thus be classed with the preparations of iron and bark. In addition, it is supposed to exert a peculiar sedative influence upon the nervous system, and is hence employed largely in the treatment of epilepsy and chorea. The stomach becomes very irritable, however, during its use; and it may therefore be questioned whether we act altogether wisely in rejecting the continental medicine, which, although mild in its operation, may be persisted in for a much longer period, and thus has a more permanent influence in allaying the nervous irritability.

Nux-Vomica and Strychnine.—These should be enumerated among the favourite remedies in neuralgia, and classed with the tonics, as they act by invigorating the system, and thus checking the tendency to periodicity. They are said to be especially serviceable when the disorder is of a remittent or intermittent character. Strychnia may be given internally, in doses of a twelfth or an eighth of a grain, two or three times a day, to persons of a leuco-phlegmatic temperament. The alcoholic extract of nux-vomica is, however, a much safer and more manageable preparation. It may be given in the form of pill two or three times a day, in doses of from a quarter of a grain to a grain.

Croton Oil.—Those who hold the opinion that neuralgia of the head and other parts of the body is dependent on disorders of the stomach and bowels, put their chief trust in the use of purgatives for its cure, and for this purpose croton oil is by them especially recommended. Undoubtedly, it has been at times most serviceable. Sir Charles Bell, its chief advocate, details several instances of its successful employment. Dr. Allnatt and other writers have added to the list. But it appears to me that the virtues of croton oil, and aperients in general, have been too much overrated. I have tried them repeatedly, and in the exact manner recommended by the above gentlemen, without benefit. Still I can well imagine cases obviously depending upon derangement of the *primæ viæ*, where their administration is plainly indicated. As previously suggested, it would be well to begin the treatment, in all instances, by a course of alterative aperients, as a suitable prelude to the exhibition of more potent remedies. They do good in various ways. They remove possible sources of irritation, restore the secretions to a healthy standard, improve the general health, and determine from the head and chest. The form of medicine employed by Sir C. Bell was the following:—

B Ol. tigllii crotonis, gutt. j.  
Mas. pil. colocynth. co., ʒj.  
Misce et fiant pilulæ xij.  
Mitte pil. galbani comp., xij.

One of the purgative and two of the gum pills to be taken on going to bed. By perseverance in their use, as often as the strength of the patient would admit, Sir Charles says he cured five patients in succession; but, singular enough, he was not so successful in subsequent trials. In some cases they appeared only to relieve a little; in others, to be quite useless. In this great surgeon's hands, therefore, this medicine was by no means a specific. Other practitioners give the croton oil in small divided doses, combined with stomachic aperients, as in the following formula:—

B Ol. crotonis, m. j.  
Pil. rhei co., ʒj. Fiant pilulæ xij.

This is, perhaps, as good a method of administration as any. One or two of the pills should be taken each night at bedtime. Sometimes I have combined the oil with syrup of ginger or orange-peel, so that a teaspoonful contained a dose.

These are the general, internal, or systemic, remedies recommended by Dr. Downing.

## MEDICAL TRIALS.

## BATH COUNTY COURT.

*Action for Malicious Arrest.*

Bourn v. Cox.

THIS was an action brought by Mrs. Bourn of Kingsmead-terrace, as the next friend of her son, Francis Bourn, a minor, who has recently emigrated to Australia, against W. A. Cox, Esq., surgeon of this city, for a malicious arrest. Females were ordered out of court.

Mr. Saunders opened the case to the jury, and proceeded to detail the facts of the case. The plaintiff was a young man, named Francis Bourn. His father died some years ago, and he had since, and till very recently, resided with his mother, on Kingsmead-terrace. The mother had an independency, and the son was an apprentice to Mr. Hooper, upholsterer and appraiser. He was aged nineteen, and on becoming of age, would be entitled to considerable property by his father's will. Mr. Cox, the defendant, was a surgeon, residing in this city, who, among his fellow-citizens, enjoyed a very high character. In July last, the young man, Mr. Bourn, was unfortunate enough to incur the venereal disease. Mr. Field was the ordinary medical attendant of the family; but the young man, probably from feelings of delicacy, instead of consulting him, went to Mr. Cox, and for the space of five weeks received that gentleman's assistance. Feeling, however, dissatisfied that he did not get better sooner, and meeting an assistant of Mr. Harries, surgeon, at Sydney Gardens, he told him of his case. The assistant advised him to apply to Mr. Harries, and the young man subsequently did so. The last time he went to Mr. Cox's house he did not see that gentleman, but he saw Mr. Lawrence, his assistant who gave him a bill for the assistance he had received, the amount of which was £2 3s. 6d. He did not pay the amount, but said he would have another bottle of medicine, which, at 2s. 6d., would make Mr. Cox's claim upon him £2 6s. Mr. Bourn went to Mr. Harries, who found that the disorder was of so light a kind as would almost cure itself, and he took the young man in hand and completely cured him, his charge for which was 6s. Mr. Bourn, like many others, was taken with the gold mania, and, with others, resolved to go to Australia. It was not his intention, however, to remain there long, because at twenty-one he would become entitled to his property, so that in about two years, in all probability, he would be back again. During Mr. Cox's attendance upon him, he frequently mentioned his intention of emigrating. The vessel, the *Winchester*, was lying at Bristol, and on Saturday, 7th of August, Mr. Bourn was at Bristol, superintending the arrangements for his voyage, the vessel being expected to sail on the following Tuesday. Mr. Cox heard of this, he got into a great fever about his trilling bill of £2 6s., and instead of going to Mrs. Bourn, the mother, who would have paid the amount twenty times over rather than her son should fall under reproach, or to his half brother, Mr. James Bourn, who was a respectable tradesman, and who would have paid the bill twenty, aye, fifty times over rather than his brother should be so treated,—Mr. Cox, however, instead of applying to the young man's friends, immediately resorted to the power given by the Absconding Debtors' Act, to arrest a person whose debt was above £20. In order to avail himself of this power, Mr. Cox, by some process which he (Mr. Saunders) could not understand, screwed up his conscience, and made his bill of £2 6s. into one of £21 5s. Upon his making an affidavit that his bill amounted to the sum, his Honour granted him a warrant, and thereupon Mr. Cox, his solicitor's clerk, and an officer of the court, at once proceeded to Bristol, and found Mr. Bourn on board the vessel superintending his arrangements. He was called out of the ship, and told he was arrested for a bill of £21 5s., which he owed Mr. Cox. He expressed his great surprise at this, and said that the bill of that gentleman only amounted to £2 6s. Mr. Cox thereupon made some remarks about that being no matter, and that he could charge what he chose. The young man said he had no means of paying,

and the officer asked him if he could find bail. He said he had an uncle residing there; but Mr. Cox, it appeared, refused to accept bail, the consequence of which would have been that if the young man had not settled the claim, he would have been detained, his passage be forfeited, and the company of his friends with whom he was going lost to him. The poor young fellow, then, having £15 in his possession, gave the whole to Mr. Cox, and he having an eye to the money, said he would take less than his claim, and he (the defendant) accordingly took the sum of £15 in full discharge of his bill and costs. He (Mr. Saunders) had no hesitation in describing this as a gross perversion of the power of the court. Mr. Bourn was obliged to come back to Bath and tell his mother what had occurred. Up to the time she had never heard of her son being so afflicted, and this was a point he should refer to by-and-by. She was naturally very indignant with the treatment her son had received, and in company with him and a friend named Mr. Wiggins, she had an interview with Mr. Cox. The conversation he would not detail now, as that would be given in evidence, but Mr. Cox on that occasion seemed to have considered that he had a right to charge what he chose. Now if he ran away with that idea it was a very fallacious one. Any man might charge what he liked—a grocer might charge £100 for a pound of tea, but he couldn't recover it. The law required that the charge should be a reasonable one. In this instance, however, the case did not depend upon the question whether the charge was fair or unfair, reasonable or unreasonable; but the complaint was that for vicious purposes Mr. Cox had trumped up a charge in order to be able to arrest the young man. They said that he had trumped up what he knew he had no right to, and had raised up his charges for the vicious purpose of obtaining a warrant against Mr. Bourn. If the warrant was obtained by these means, Mr. Cox was liable to compensation by damages to the person injured. The plaintiff, having a great interest at stake, it did not suit his purpose to remain in this country, and he therefore left on Thursday, the 11th of August, and they were consequently deprived of his evidence; but he (Mr. S.) believed that, after hearing the testimony of the witnesses, the jury would have no doubt left upon their mind as to what ought to be their verdict. Mr. Cox had not given any bill except the one given by Mr. Lawrence, and which he subsequently repudiated; but if this bill was not a genuine one, it followed that all his subsequent proceedings against the young man were taken without any application for payment being made to him. When his friends, however, subsequently, with a view to these proceedings, made an application to him for the particulars of the charges, he had sent a bill which more than anything else showed Mr. Cox's folly and irregularity for a more monstrous concoction he had never heard of. To say that such a disease existed, and without the mother discovering any symptom, was absurd, and proved that the bill was a trumped up one. He should call upon Mr. Harries who attended the young man after Mr. Cox, and he would tell them that the disease was in the mildest form, and he would gladly undertake a hundred such cases at 10s. each. What, then, could be their conclusion but that this was a trumped up charge. If the difference in the two bills had been small, say from £18 to £21, nothing would have been thought of it, but an increase from £2 to £21, showed that such a course could only have been taken to enable Mr. Cox to obtain a warrant. If he proved that Mr. Cox had grossly misconducted himself, then he must be content to suffer the consequences. The Absconding Debtors' Act was passed for a good purpose, but it was a powerful engine in the hands of those who used it improperly. It had been used, he believed, improperly in this instance, and if he proved this, it was a case which would bring down upon Mr. Cox a vast amount of censure. In this court the highest damages they could award was the sum of £50, and that amount he thought they would consider a very low estimate of the injury sustained by the plaintiff. This was a very aggravated case, and, as he had said before, he much regretted that it should ever have occurred. If

their verdict was against Mr. Cox, it would, no doubt, bring the odium of his fellow-citizens upon him ; but they had a public duty to perform, and if Mr. Cox chose to act as he had, he must bear the consequences.

Mr. Saunders then put the affidavit made by Mr. Cox in order to obtain the warrant of arrest, in which he swore that the debt due to him from Francis Bourn amounted to £21 5s.

George Wilcox, one of the officers of the court, arrested Francis Bourn on board the *Winchester* ; he told him he was arrested for a bill of £21 5s. ; Bourn said in surprise, £21 5s., why your bill is only £2 6s. ; Mr. Cox said how do you know it is only £2 6s. ? he replied, I had the bill. We then went out, and going along I asked Bourn if he had any money ; he said he had he thought about £12 ; Mr. Cox and he began talking ; Mr. Cox still persisted that his bill was £21 5s. ; Bourn said how can that be ? Mr. Cox said never mind, I can charge you what I like ; he said he did not want to hurt Bourn, or prevent his going abroad ; Bourn then said he had £15 ; Mr. Cox said he would take that ; I asked him if he would give a discharge in full for that ; he said he would, and did so.

Mrs. Betty Bourn, mother of the young man, deposed that she always assisted in making Francis Bourn's bed whilst he lived with her, but she never saw any symptoms of her son been afflicted with disease ; after her son came from Bristol, she went with him and Mr. Wiggins to Mr. Cox's house ; I asked Mr. Cox why he had arrested my son ? he said he would give no explanation ; I replied that as a mother, and as my son was a minor, I should ask for a bill ; he said I shall give no bill ; but as the affair is settled I shall say no more about it ; then I said, Mr. Cox how could you suppose that a young man not of age could have £20 to pay in so short a time ? Mr. Wiggins before that asked Mr. Cox how long he had been attending my son, and he said about two months ; to which my son replied, "No, not above five weeks ;" Mr. Cox said if he had been paid at the time the thing would have been waived ; I then said you mean that if paid at the time it would not have been £20 ; he said if it had been paid at the time it would have been a very different thing ; I said I suppose you have been obliged to make it more than £20 in order to take out the warrant ; he replied yes ; then I said, Mr. Cox you have taken a false oath : you know you have ; if ever a false oath was taken in a court of justice, you have taken it against my son ; he made no reply ; I then said, the name of man ought to be taken from your shoulders. Mr. Cox then seemed irritated ; I said how could you make £2 6s. into £21 5s. ? he said it is for medical advice, and I can charge what I like ; I replied, then I wonder you did not make it £100 ; he replied, and so I could if I chose ; I then said if you have given medical advice I will have legal advice. My son asked for the assistant, and said he had given him a bill for £2 6s. ; Mr. Cox said it was done without his knowledge ; since the bill has been given by Mr. Cox, my son James, with my consent, has had it printed and circulated.

Mr. George Wiggins deposed that he was related to Mrs. Bourn, and that he accompanied her and her son to Mr. Cox's ; he said to Mr. Cox he understood he had tendered a bill for £23s. 6d., and arrested him for £21 5s. ; Mr. Cox said the bill was tendered without his knowledge ; I remarked upon the amount, and asked Mr. Cox how long he had been attending the young man ; he replied about two months ; I said I could not make it more than six weeks ; Mr. Bourn said no not five ; Mrs. Bourn asked him if he had any right to make such a charge, and he replied that he had for medical attendance ; then you might have made it £100 ; Mr. Cox made an observation that Bourn had often evaded seeing him, and that he asked him who his medical attendant was ; and that he said Mr. Field, when he told him he had better see Mr. Field ; Mrs. Bourn asked for a bill of particulars, but Mr. Cox said he had got his money and he should not give any.

Cross-examined : Mr. Cox did not say why he advised Bourn to apply to Mr. Field ; he did not say that he told him.

George Lawrence, assistant to Mr. Cox : Recollects Mr. Bourn, jun., coming for advice on one occasion, 24th July ; had not made out a little bill to Mr. Bourn, nor any bill to my knowledge ; nothing was said to me about a charge of £2 3s. 6d.

Mr. Slack, in cross-examining, was objected to by Mr. Saunders in point of form ; witness was aware in reference to disease to which the plaintiff was subject, that a new medicated bougie had been introduced ; the application of the instrument was of such consequence as to require Mr. Cox's direction ; he has frequently charged a guinea for such an operation ; recollected a case in which Mr. Bourn attended two or three times a-day ; had known Mr. Bourn sometimes in consultation with Mr. Cox half an hour ; had known him to be there before ten o'clock, and to have kept him afterwards while his carriage has been waiting to take him to his daily visits. Mr. Bourn appeared to be very ill ; in cases such as his, the operation required was anything but pleasant.

George Topp examined, assistant to Mr. Harries, surgeon : Has known Mr. Bourn from a child ; met him in July and found him labouring under disease ; he called on Mr. Harries, and told him he had been under Mr. Cox ; am used to such cases, and am of opinion that his case was common gonorrhœa ; Mr. Harries examined him in my presence. [The witness described the stage of the disease under which Mr. Bourn was suffering, which was not such as to require the extreme treatment, nor any difficulty in the application of the instrument used ; the instrument might have been frequently used, but if so it was likely to be injurious.] Mr. Harries supplied him with medicine, for which he charged him 6s., and he became quite cured ; had a patient been under a surgeon six weeks for the disease, no such sum as £21 could have been incurred as a fair charge ; I think the bill is not a fair one, but a manufactured one.

Cross-examined : I am a surgeon's assistant, but have not passed a medical examination at Apothecaries' Hall, or the College of Surgeons ; thirty passes of this instrument in five days would have been bad practice ; have some respect for the late Sir Astley Cooper. [Mr. Slack read an extract from that surgeon's work, in which he recommended its use twice a day, asking the witness if he did not agree with him.] The witness said, I differ from Sir Astley Cooper on that point ; the cross-examination in detail extended to much technical explanation, which was checked by his Honour as exceeding the due latitude of the rules of evidence.

Re-examined : Was twenty years resident apothecary at the Bath United Hospital, since which I have been with Mr. Harries five years ; the different symptoms described in the bill could not have co-existed in the same patient, but one must have preceded the other ; saw Mr. Bourn dance at the Odd Fellows ball as others did.

Mr. Alexander Harries, surgeon, deposed that, on the 25th July, Mr. Bourn was examined by him, and was suffering from simple gonorrhœa, describing the symptoms and appearances as of a very light character ; had never during his practice observed the two diseases described co-existing in the same patient ; gave him three bottles of medicine, and he was soon well ; would be very happy to undertake the cure of a 100 people in a similar way for 10s. ; the bill produced is such a one as he never saw in such a case before ; the treatment said in the bill to be adopted was totally different from his.

By the Judge : Poulting and fomenting did not belong to surgical attendance ; the case professed to have been created in the bill would not in his judgment be cured in the time stated ; the external appearances of the patient when I saw him were not consistent with the description given in the bill.

Cross-examined : Such a case was very remarkable if a real one ; such a patient would receive attention on board a ship from the ship surgeon, as at home ; had never seen the two diseases exist, and the best writers agree in the opinion that they do not ; Sir Astley Cooper was out of fashion now ; Sir Astley Cooper would have said aye to

this question, but Mr. Hunter and the surgeons of the present day would say nay.

Mr. Skeate, surgeon, heard that Mr. Cox had arrested Mr. Bourn, and that his friends were annoyed and were about to take legal proceedings; might have said to him that the bill was an overcharge; but do not recollect the particulars of the conversation; Mr. Cox said the bill was a genuine one, and he should charge full fees; the public had been talking about the overcharges; I told him he had better go and make it up with them.

By the Judge: He told me he should charge half a guinea, and a guinea, where it was not usual.

By Mr. Saunders: I told Mr. Cox that I would rather give a £100 than not settle it.

By the Judge: The treatment described in the bill produced is inconsistent with the case, and would increase the disease.

Mr. Field, surgeon, examined: The bill is a very exorbitant bill, and one which I could not have made conscientiously for the same case; had everything been done which is set down, the charges would have been excessive.

By the Judge: Never saw a case with the same symptoms coexisting; it is possible the two diseases may be contemporaneous, but in all my experience I never witnessed it; some use of the instrument twice a day was highly improper.

Cross-examined: Supposing the bill to be a correct bill, had I been in such a case, I should see no objection to an explanatory appendix like that in the bill produced.

Mr. Bartrum was called, and on examining the bill said, it was the most unsatisfactory one on such a case he ever saw, and that the treatment for the disease described was improper.

By the Judge: The particulars which the bill described of medicine and treatment to me appear to be, with respect to the latter, very extraordinary, and some of the former would be considered *infra dig.*, and only belongs to nurses; in other points of the case, Mr. Bartrum agreed with the other medical witnesses.

Mr. Bagshawe, surgeon, examined, spoke of the bill and the treatment to the same effect as Mr. Bartrum.

Mr. Slack said that if Mr. Saunders chose to call Mr. Cox as a witness, he was ready to tender his books for that purpose.

His Honour said, he should throw the onus of rejecting such evidence upon Mr. Cox himself.

This closed the case for the plaintiff.

Mr. Slack offered some legal objections which he supported by several cases; but after a lengthened discussion, they were overruled. Mr. Slack then addressed the jury. This was an action for malicious arrest; but he entertained a very strong view of the case, and he said without hesitation that the tables ought to be turned, and instead of an action being brought against Mr. Cox for malicious arrest, it ought to have been brought against those who were maliciously persecuting him. Never in the course of his (Mr. Slack's) professional career had he known a professional man so unfairly dealt with and so ungenerously treated. What were the facts? Here they had Mr. Bourn afflicted with a most serious and odious disease, they had him resorting to Mr. Cox, and that gentleman devoted to him the most assiduous attention, seeing him twice a day for some weeks, and doing everything which his professional skill suggested to rid his patient of the disease from which he was suffering. It was not open, therefore, he thought, to the learned counsel to take parts out of the bill of particulars given, and throw dirt on the rest; the bill ought to be taken as a whole, and then it would show the great diligence Mr. Cox had shown in allaying the sufferings of Mr. Bourn. It had been said that the bill was trumped up; but he had asked all the witnesses against Mr. Cox what was that gentleman's character, and they had all concurred in saying he was an honest man. Now an honest man could not put down charges for attendance which he did not give, and therefore the bill could not be trumped up. The question then arose as to the necessity for so much attention. The fact was, that Mr. Bourn's was an

extraordinary complication of diseases when he was attended by Mr. Cox. Mr. Harries said, it was slight gonorrhoea when he saw him; and that he only gave him three bottles of medicine, but he did not venture to say that the young man was cured by these three bottles. The fact was, that the man was cured before he went to Mr. Harries of the disease, and there were some slight remains left for which Mr. Harries' medicine was sufficient. It was patent that the cure was effected by Mr. Cox. It was said by the medical witnesses that the two formidable diseases described had not existed in one individual at the same time within their experience; but they did not venture to say that such a state was impossible. He maintained that this case upset that doctrine, and that such doctrine must now be exploded. Mr. Slack then referred to the state of the law which does not give the power of arrest, unless the debt amounts to £20, but the spirit of the law was no doubt to prevent absconding debtors from cheating their creditors, and he did not think there was a person who could believe that it was Mr. Bourn's intention to pay Mr. Cox before he left England. One little circumstance was remarkable. His mother had received from him a list of debts, but Mr. Cox's name did not appear in it. It was clear that after all the attention bestowed upon him, this was a debt he intended to evade. But supposing he did intend to pay, was that a fact of which Mr. Cox could be cognizant? They judged men by their actions, and all the acts of this young fellow went to show that he had no intention of paying. On the day before he was expected to sail, Mr. Cox called at his house, and hears from the servant that he is gone to Bristol, and that his mother was gone to see him off. His conviction was immediately that it was intended to deceive and cheat him, and he therefore adopted the only course left open to him of seeking a warrant for his apprehension. His bill, he maintained, was a fair one, and when the young man expressed his surprise at the amount, Mr. Cox told him he could satisfy him that his claim was a just one. If Mr. Bourn did not think so, his remedy was open—he could have had the matter settled in court. He was not bound to compromise, but when the offer was made he at once saw that his interest lay in that direction, and he paid £15. He (Mr. Slack) on the part of Mr. Cox said that his charges were perfectly fair and honourable, and that the amount could not be judged of by parties who had not seen the case, because they were ignorant of the amount of skill and attention it required. After pointing out some extraordinary features in the present case, Mr. Slack said the responsibility of a medical man ought also to be borne in mind in judging of his claim. It was said that some of the charges were for nurse's work. The fact was, that Mr. Cox under the circumstances (the young man being particularly anxious for secrecy) had done that for him which he did not usually do in such cases. Was it to be held, then, that because a gentleman descended to such drudgery, he was not to be paid for it? Every one must see that his claims were the greater on that account. Mr. Slack then contended that these proceedings were very ungracious, and that Mr. Cox, after succeeding in detaining Bourn, had shown that he had no malicious feeling towards him, or he would not have consented to take £15 in discharge of his claim. But having been obliged to pay the £15, the plaintiff now turned round and said Mr. Cox should pay £50 for endeavouring to obtain his own. Would the jury encourage such a proceeding? What had been the damage sustained by Mr. Francis Bourn? He was not detained; but had gone on his voyage. Mr. Cox, however, having succeeded in obtaining the £15, Mr. Bourn's friends were traducing him in every way. Why when the bill of particulars was sent in, and be it remembered Mr. Cox was not obliged to send it, the next step was that Mr. Bourn got the bill printed and distributed all over Bath, with the view of prejudicing his client. This showed that it had been attempted to run Mr. Cox down, and ruin him. The learned counsel asked him if he was ashamed of the bill? He was not. The bill arose in this way. Being asked for the particulars, Mr. Cox had departed from his usual custom, and that of

the profession, and gave minute particulars of all he had done to the patient. It was dragged out of him, and he expressed his repugnance by the following note which he appended to it: "The above is an explanatory bill of the charges in my ledger. I make it out thus that the parties may have some idea of the nature of the case, and of the services rendered. Each attendance occupied a very considerable time. I regret in self-defence to set out my charges so minutely." He said it was creditable to Mr. Cox that he had given these particulars, and that if he had not done so he would be blamed. Mr. Slack then referred to the fact that Mr. Cox had discovered a new mode of treating this disease, and said he deserved consideration in consequence, and that plaintiff had derived the advantage of that discovery. He then repudiated the idea that Mr. Cox entertained malice against the plaintiff, and dwelt upon the important fact that the other side had totally failed to prove that any bill for £2 6s., as alleged, had ever been sent in by Mr. Cox or his assistant. In fact it was positively denied. He maintained that Mr. Cox had been much maligned upon this point, and that he was an injured man. He had looked through the bill and found that £5 10s. out of it was for medicine, and the rest for attendance. Mr. Cox, however, only got £15, and out of that he had to pay £6. 6s. for expenses. Deducting this and the medicine, it left the trumpery sum of £2 for each attendance. He put it to any reasonable man if that was too much? The learned gentleman then adverted to the refusal of Mr. Saunders to call Mr. Cox as a witness, and stated that although it would lay him open to a reply from the learned counsel, he should himself put Mr. Cox into the witness-box and produce his books to the court. He then concluded by contending that there was no case for damages, and by appealing to the jury to preserve the reputation of his client, which by these proceedings was so assailed.

Mr. Cox was then examined. He said the patient entreated him to use every means to cure him quickly, as he was going abroad; he also told him that he had been under a chemist for two months, and witness found his system saturated with copaiba; the state of the young man (according to witness's description) was exceedingly bad, and required extraordinary attention and treatment; the treatment was successful, and the patient was cured of the diseases for which he consulted him; on the Friday previous to the Saturday the warrant was issued, he went to the patient's house and inquired if Mr. Bourn was at home; the servant replied that he was gone to Bristol to depart for Australia, by a ship that was to sail at twelve o'clock on the following day; he then asked if Mrs. Bourn was at home, and the servant stated that she was gone with him; he asked if she was going to remain there to see him off, and the servant said she did not know; he believed then that Bourn intended to cheat him, and went home and made out the bill immediately from his ledger. The ledger and day-book were here produced. He then made an affidavit of the amount of the bill and procured a warrant for his arrest; he sent the officer to the vessel to call Mr. Bourn out, because he was desirous of respecting his feelings and the feelings of his mother if she was there; witness took the bill in his hand, and told Bourn the amount, and said he had not taken these proceedings without looking to the end, and with a view to its being settled in a court of justice; he pleaded poverty, and named his brother as security for the amount, but not as bail; he knew very well that it did not require his (witness's) sanction to his finding bail; witness refused to accept the brother as security; they then went into a private room, and witness told him, "Now you have tried to cheat me, but have not succeeded; I have no wish however to hurt you, and if you pay me £15 I will give you a discharge in full;" he then paid him £15, and he gave him a receipt; witness afterwards offered him a seat in his conveyance to go to Bath, which he accepted; on their way Bourn began talking about his having no intention to cheat witness, when witness asked him "how it was that he and

[another patient who has gone off in the same vessel without paying him], came to be sitting down and talking over the matter; were you not laughing to think how nicely you had done the doctor?" To this question Mr. Bourn made no denial; the witness then described the interview between himself, Mrs. Bourn, Mr. Bourn, and Mr. Wiggins. He denied that he had said he purposely made his bill above £20, and said when he stated the disease, Mrs. Bourn said she thought so from stains on him; he never met with such a complexity of bad disorders in one person as in this.

Cross-examined: I should call the cure of this extraordinary case a good one. I think any properly educated man with proper attention might have effected the cure; it never occurred to him to apply to Mr. James Bourn for the money; he was the last man in the world he should have thought of applying to.

His Honour, after examining the books produced by Mr. Cox, drew attention to the fact, that the charges for attendance daily were interlined on each occasion between the charges for medicine, which he considered a very suspicious circumstance.

Mr. W. Bush, surgeon, deposed, that he attended between 2,000 and 3,000 patients yearly; he was senior surgeon to the Eastern Dispensary, senior surgeon to the Bath Eye and Ear Infirmary, and had a large medical district under the board of guardians; he had practised in Bath for thirteen years; he believed syphilis and gonorrhoea might exist at the same time in one individual; he also considered Mr. Cox justified under the extraordinary circumstances in which he was placed in the treatment he had adopted; he had not come into court as a witness, but gave evidence from a sense of justice between both parties.

By the Judge: He thought Mr. Cox was justified in making the charges he had if he thought proper to do so; the sum was higher than in usual cases, and he should have thought it exorbitant had he not heard Mr. Cox's evidence of the time and attention required.

Mr. John Barrett, surgeon, deposed that in early life he had had great experience at the Lock Hospital, London, which was particularly devoted to venereal cases; he was induced to give evidence by hearing the evidence of Mr. Cox; he was of opinion that the two diseases described by Mr. Cox as existing in this case might exist together; he came into court deeply interested in the case, and with a strong prejudice in consequence of what he had heard out of doors against Mr. Cox; since hearing Mr. Cox's evidence his opinion of the case had been quite changed.

Both these gentlemen were cross-examined, but nothing of interest was elicited.

Mr. Saunders then addressed the jury in reply. His Honour summed up very impartially, and the jury, after a consultation of ten minutes, returned a verdict for the plaintiff. Damages, £15.

**IODIZED CIGARS.**—It has been suggested by Kletzinsky that the iodized cigars introduced by Chartronne and Bertson might be advantageously used more generally in medicine. He finds, 1st, that a sufficient quantity of iodine may be found in a cigar which, after being iodized, has been lying exposed for four days in a warm room (we may observe that the process of iodizing consists in lightly washing a cigar with an alcoholic solution of iodine, or in exposing it for a few minutes, in a closed box or vessel, to the simultaneous action of iodine vapour and steam); 2nd, the greater part of the iodine which has been taken up is found in the ash as iodide of potassium, calcium, and magnesium; 3rd, the smoke, after being passed through cotton wool to retain any particles of ash, and then conducted through a neutral solution of starch, did not give rise to the slightest blue colouration, even after the neutralization of the carbonate of ammonia contained in the smoke, with acetic acid. On the addition, however, of chlorine water or nitric acid, a blue tint was evolved, showing that there was a little iodide of ammonium, although no free iodine, in the smoke; 4th, after a few puffs, the saliva and buccal mucus gave distinct, although slight, traces of combined iodine; 5th, after smoking an iodized cigar, iodine could generally be detected in half an hour, and often earlier, in the urine. —Kletzinsky in *Wein. Med. Wochen. and Prov. Jour.*

DUBLIN: WEDNESDAY, OCTOBER 20, 1852.

## PAYMENT IN PRIVATE PRACTICE.

WE this day devote more space than we can well spare for such a purpose, to a report of a trial between Surgeon and Patient which has attracted a good deal of attention in England amongst "medical men." We have no personal knowledge whatever of the parties, and only direct attention to the matter in order to make our readers acquainted with the method of "doing business" in England. At the present moment much difference of opinion prevails in Ireland as to the course to be pursued in future with respect to persons unable to pay the guinea *honorarium*; and it is well to exhibit the working of the plan adopted elsewhere in such cases. Not that we feel inclined to recommend it, especially as thus carried into practice; but that we would warn our brethren against the dangers to be apprehended from any fictitious substitution of one charge for another. It is evident that when the General Practitioner supplies medicine and charges for it, he must have adequate remuneration for this part of his service; but he is inevitably tempted to increase his profits in this way by an excessive administration of remedies, until in the sequel this becomes the only means by which he can obtain payment for his labours. He finds, as he proceeds, that many object to charges for attendance as well as for medicines, and these he is compelled to wheedle into a quiet acquiescence in the law which inculcates that the labourer is worthy of his hire; but in doing so he embarks in a trade which requires the practice of arts which conscientious men would gladly avoid. In the case before us this is well exemplified; for although the Surgeon-Apothecary in question claimed adequate remuneration in the shape of fees, he demanded additional payment under pretence of medicinal remedies, which, from the "bill of particulars" before us, were obviously unnecessary. How far he is blameable for this, or how far exonerated by the plea of custom and usage, we cannot well tell; but of this we are quite sure, he has had his character placed in jeopardy by the proceeding. As to the individual delinquency, if any, we do not care to express an opinion; all we want is to elicit an explanation which will inform us as to the prevalence of this practice in England. We wish to know whether the Surgeon-Apothecaries or General Practitioners in this part of the world are in the habit of supplying excessive quantities of medicine to their patients, in order to obtain remuneration for their services, which they could not obtain by direct means? If such a habit, usage, or custom prevails, we cannot but consider it a dangerous one for application in Ireland; and therefore do we dwell upon the subject, in order to bring our brethren embarking in a new career to consider well whether the safest course may not be a reliance on fees, however small. We are fully aware that there are practitioners, both in England and Ireland, who derive a livelihood from small fees in the shape of payment for pills, powders, and bottles; who must cajole the customer by giving him something tangible for his money: but this, after all, entails a vast amount of trouble and expense, as well as a very serious diminution of a man's self-respect. In the common routine practice of the Apothecary "over the counter," the method does not seem so open to objection; it is when, as in the case

before us, a man in extensive and lucrative practice adopts it, that the risk of reproach is incurred. Be the consequences, however, what they may in England, here in Ireland, or in the metropolis at least, they are of the most deplorable nature. If an English General Practitioner drugs his patient to swell his bill, we can leave the gentleman to settle the matter as his conscience suggests; but when the Apothecary employs a Physician or Surgeon to effect this object for him, it is then high time for us to complain. That this sometimes happens, we believe is notorious; but we venture to hope that the practice is rather decreasing than otherwise, and that it is more adopted by particular individuals than by the profession at large. That some men, without disguise, habitually write prescriptions to benefit the Apothecaries, and thereby to secure their "good word," is well known; but as patients have learned that such tactics are practised, the plan does not always succeed, and the "drugging doctor" loses as much as he gains by his speculation. It is also well known that particular Practitioners are "called in" by certain Apothecaries, who have ascertained their powers of adaptation; but as this leads to a system somewhat analogous to exclusive dealing, it is not found in the sequel so safe a course to pursue. Of the case in which the Surgeon, or whatever else he may be, becomes the confederate of an Apothecary of the same stamp as himself, "hunting in couples," we need not say much: such cases are exceptional ones, although they do really occur. But we cannot help expressing our abhorrence of the one man who writes prescriptions for the sole purpose of rewarding as an agent, and of the other who acts as his touter in return. Such persons are co-partners or confederates, and their proceedings are in fact little less than downright swindling. Notwithstanding all this, it is cause of congratulation that cases like this now before us have seldom met the public eye in Ireland. It is also cause of congratulation that in the case before us, the reproach, whatever it may be, rests on the shoulders of the principal party. There was no consultation, no "calling in," to "cover him"; all was done boldly on his own responsibility. We have a communication before us on this subject, but so much of our space is occupied by it already, that we must postpone its insertion.

## FISHING LETTERS OF INSURANCE COMPANIES.

IF we had not become familiar with the practice, should we not view with amazement the cool impudence of a trading firm, which, without the slightest claim to any such service, demands a certificate from a Surgeon without any intention to pay for it. Yet such is the state of the case with regard to Insurance Companies, which have the audacity to persevere in this most unjustifiable proceeding. It is abundantly evident that these "gents" avail themselves of a hitch in the Surgeons' affairs to extort this gratuitous service. They knew that he will be unwilling to disoblige a patient by refusing such a certificate, or by charging him for it after he has paid for attendance on him, and meanly go behind him to execute this manoeuvre. Now, when we find a body of traders playing such a trick as this, the conclusion appears to us inevitable that they are prepared to play similar tricks in other directions; and our firm belief is, that they do play them, having first effectually muzzled the press by advertisement bribery. Dr. O'Rourke is entitled to the thanks of our profession for his resistance to the imposition, as explained under the head of correspondence.

## CORRESPONDENCE.

## THE MEDICAL CHARITIES ACT.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—I perceive the attention of "One of the late County Secretaries" has been directed to my communication of the 6th instant in the Press, with respect to holding two dispensaries by one medical officer, and that in doing so "existing rights" were only preserved.

Now, may I beg to ask him, are there no rights of the poor to be preserved—are they to be thrown overboard as a class not to be looked after? How was it that the Poor-law Commissioners so often refused, in the first instance, their sanction in holding two dispensary districts? What new light came over them to sanction it afterwards? Surely it was not the large extent of districts, the number of townlands that were added, actuated them. It is in proof that officers who were sanctioned to hold two dispensaries were peremptorily called on by the Commissioners to give up one of them. Can it be contended for that two extensive districts, the waiting on two boards of guardians, the attending four days in each week, and the keeping of two sets of the most intricate and elaborate set of books, independent of being exposed to travel to the extreme ends of the districts, some forty miles back and forward daily, could be efficiently done by any one officer without neglecting his duty to some.

I would say remunerate the medical officer, but do not impose on him duties he cannot efficiently perform, by pluralities of dispensaries. Let there be one uniform mode of acting; let one principle guide all transactions in the different appointments by the Poor-law Commissioners. I feel an anxiety for the welfare of the profession as well as the "Secretary," but I will not allow the violation of principle by men without remonstrating.

With regard to the desire of your other correspondent, A Subscriber, wishing for the "names and localities." If he be an independent member of parliament that would bring the proceedings I alluded to in my communication before the House of Commons, I could have no objection to put myself in communication with him; or if he be a person in authority who could explain the inconsistency of the Poor-law Commissioners, I shall feel much pleasure in giving every information in my power, both as to "names and localities;" but otherwise, I would say, "cui bono," as I cannot see how we could investigate the matter and come to the facts of the case, except he is in some way connected with the Poor-law Commissioners. Your "Subscriber" is mistaken that I am dissatisfied with all parties concerned. The parties I find fault with are the Commissioners, who could in the first instance prevent much ill-feeling by appointing the medical officer at once, if they had sufficient grounds to do so; if not, why did they do it afterwards. A CONSTANT READER.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—Having seen in your number of the Press of the 6th inst., a letter signed "A Constant Reader," on the subject of pluralities of dispensary districts being held by one physician, I beg leave to observe, that in my opinion it is not a question for the consideration of the profession in general, but clearly and distinctly concerns the individual himself and the ratepayers of the district; they are and should be the best judges as to whether the duties could be properly performed; consequently, I submit that if the same medical man be elected by the committees of the two districts, and his election be confirmed by the authorities, the profession should no more interfere with him than they do with the fortunate man who holds a county infirmary, jail, fever hospital, &c., and receives a distinct salary for each.

If a district be very large, and the remuneration very small, then the profession should exert itself to procure justice for the hardworked and illpaid members; but it is fallacious to confound the two questions.

Now, sir, I happen to know the particulars of the very case which the "Constant Reader" had in view when he penned his rather intelligible communication. The successful man held for years two dispensaries, with districts almost as large as the new ones, and nearly coincident, and he fulfilled the duties to the satisfaction of every one—rich and poor; and knowing that not one-half the number of persons are qualified to receive medical aid under the new system, as under the old, still I may safely conclude, though his duties be more extensive, that he is quite equal to the work—he lives in the centre of them—he is young and active, and confines himself solely to professional avocations. On the other hand, the non-elected (I would not call him for the world the disappointed) candidate lives in a town away from the district, say, fully fourteen miles from parts of it. He, no doubt, is fully qualified for a dispensary, keeps a medical establishment, retails drugs, and I know not what else; and surely your readers will appreciate the wisdom of the Commissioners in preferring the man they did, who only professes to be physician and surgeon. I cannot say how far they were influenced in their decision by the fact, that the non-elected came forward in the teeth of a pledge, that he would not oppose the other candidate. I think that under those circumstances it would have evinced more prudence to allow the matter to rest in peace; but when the virus of disappointment gets into the judgment, it naturally impairs its functions.

I have, sir, a love and esteem for our profession. Its position, however, will depend in a great measure on the position of its members with regard to honour and respectability, and I believe that to perform the duties of even a dispensary district faithfully, sedulously, and satisfactorily, will conduce more to the exaltation of our profession than the breaking of a pledge, even were the doing so to secure his election. I am your obedient servant, MEDICUS.

October 16, 1852.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—In all the late numbers of the Press, I read various letters about the Medical Charities Bill. How it is working, some saying, well, others ill; but if all the committees are like mine, I do not hesitate to say it is the best act that could be passed, both for the poor and for the profession. It is a little laborious, no doubt; but when one's hands are not tied up, by being not allowed a proper supply of necessities, it is a pleasure to be worked, and to do good. The bill has only one fault, the salaries are too small. I would think for the work done £100 a year should be the minimum, but as the country is too poor at present to increase them, I would suggest that a meeting should take place, composed of the heads and professors of the College of Physicians and College of Surgeons, when the matter might be brought under consideration, and a draft of a bill to parliament drawn up, demanding one-half of our salaries to be paid out of the consolidated fund, and the other half as it is at present; and that every medical man connected with a charity should sign a petition to that effect; also they should make it a point to have a certain sum per cent. stopped out of all salaries to make up a fund which would enable a medical man (incapacitated from bad health) to receive a compensation, if only a short time in harness, and a pension after twenty years service, should he then be unable to perform his duties. Such a fund is in the constabulary and revenue police. It would be no tax on the country, as it would be from our own incomes the fund would be derived. I have no doubt if the

matter was brought properly before parliament, and that we all united, instead of growling over things we cannot help, we might succeed.

"Unity is strength," and medical men ought to have some interest with members of parliament, and the representatives of the people must be aware that we are as well entitled to be pensioned (in the way I show) as either constabulary or revenue officers. For surely fever, dysentery, and other infectious diseases, are as dangerous opponents as a cabbage-garden rebellion at Balingarry, a row in a fair, or the storming a set of smugglers over a private still. Now, sir, let us set to work at once: the government seems inclined to acknowledge our claims, let us use all our local interest, and victory is certain. Then shall we be able to insure our lives and carry out the motion brought forward by Dr. Neligan in the 10th report of the Medical Benevolent Fund Society; but the way we are at present situated, what is the use of doing so, as we may lose all by missing one payment, and I fear that good society will never be able to pay for all that would require it (however well inclined). As you are always willing to work for the good of the profession, and from your high standing in it must command attention, if you take it up it must succeed. Let there be no provincial or county meetings, let you (if you approve of these suggestions) take it up, both as a journalist and in the College of Surgeons, for surely the College has a right to exert itself in a matter so vital to the welfare of so many of its fellows, members, and licentiates. I have the honour to remain, sir, your obedient servant.

A SUBSCRIBER AND DISPENSARY MEDICAL OFFICER.

October 15, 1852.

#### INSURANCE OFFICES.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—As it is the imperative duty of all medical men to uphold their profession against an unpaid service which the insurance officer would impose on them, I beg to forward you the enclosed correspondence, to show at least that I have done my duty. I would not give the required information without a fee. Another office was applied to: from whom I got one guinea; the first losing the insurance (if it were an object) for not paying the requisite remuneration.—Yours truly,

P. O'ROURKE, M.D.

Enniscorthy, October 14, 1852.

Provident Life Office, 50, Regent-street, London.

SIR,—Being desirous of assuring my life in the Provident Life Office, I am required to produce certificates from the medical gentlemen who are best acquainted with my general health and habits, and also with the nature and extent of any particular illness from which I may have suffered. I therefore request the favour of you to answer the queries as under, and send the paper as directed per post in the accompanying envelope. Your answers, I am informed, will be held confidential by the directors.—I am your very obedient servant.

Dr. O'Rourke, Enniscorthy.

P.S. The inquiries were annexed. I omit the name of applicant.

Enniscorthy, April 30, 1852.

SIR,—Having received from your Dublin agency this morning, some queries respecting the health and constitution of Mr. —, to be answered by me, and which would be held confidentially by your directors, may I beg to say that the fee usually sent on these occasions was not enclosed, whether by neglect or otherwise. Please say it is intended to be forwarded; if not, I must decline giving the required information, for I consider it for the benefit of your society that it should be paid for. Waiting your reply, I am your very obedient servant,

P. O'ROURKE, M.D.

John A. Beaumont, Esq.,

Provident Office, 50, Regent-street, London.

P.S.—There was no reply.

#### BITTER BEER.

To the Editor of the Monthly Journal of Medical Science.

SIR,—I had much pleasure in reading the amusing dialogue, in your August number, on the late attacks on pale ale, and the means I had adopted of self-defence against such attacks. So far from feeling offended at the strictures you therein pass upon the course adopted, I, on the contrary, recognize in them a very proper susceptibility of the dignity of the medical profession, and am grateful that they give occasion for what I value especially—a high testimonial in favour of our ale—spontaneous, unsolicited, and, I might almost say, unintentional. This, sir, I have instructed my agents to insert in their advertisements throughout the public press; and I trust the proprietors of the *Edinburgh Monthly Journal* will find no objections to its appearance in their advertising columns.

Any attempt on my part towards a defence of those eminent medical gentlemen who have honoured me with their testimonials against the charge of interested motives implied in your columns, would be at once impertinent and unnecessary. Such a thought never entered my head; and you, sir, have yourself suggested their full acquittal. But I find in your number for the present month, a letter from Dr. Glover of Newcastle, which calls for some notice on my part.

The circumstance that gave rise to my application to Dr. Glover, was his writing a letter to the Editor of the *Lancet*, in which he seemed, unnecessarily, to add the weight of his professional opinion to the prejudice against bitter beer, so unexpectedly raised in the public mind, by the suggestion of the use of strychnine in its manufacture. Many distinguished members of the medical profession pronounced such an adulteration impossible. Dr. Glover, however, volunteered his opinion, that it was not only possible, but probable; and the Editor of the *Lancet* had given insertion to this letter, though certainly with a strong remark of his own on the absurdity of the supposition. Copies of these I submit.

(From the *Lancet* of April 3, 1852.)

#### "ALLEGED IMPORTATION OF STRYCHNINE."

To the Editor.

SIR,—I beg to state that I have found by experiment that one grain of strychnine will give a strong bitter taste to three or four bottles of ale, and will be efficient to even a greater extent. The wholesale price of a grain of strychnine is about a halfpenny. Probably this poison can be manufactured even more cheaply in France. There is therefore every inducement for an unprincipled brewer to adulterate his ale with this substance. Of the injurious effects of the long continued use of such a beverage, there cannot, I think, be a doubt. There is only one remedy for such adulterations—viz, for the legislature to repeal the absurd protection which now enjoys, and to levy no tax on hops, and to allow any wholesome bitter to be employed. Then I have no doubt that many vegetable bitters would be openly, cheaply, and beneficially employed.

—Yours, &c.,

R. M. GLOVER, M.D.

Newcastle-upon-Tyne, March, 1852.

[Dr. Glover and the public may feel perfectly confident that the odious allegation made by the French writer, that strychnine is commonly used in this country in the manufacture of bitter beer, is as foul a calumny as was ever invented. It is just possible that a few unprincipled and needy speculators may have resorted to the use of that poisonous drug; but that houses of established reputation and wealth should have employed it in their manufacture, is a supposition far too preposterous to be entertained.—*Ed. L.*]

Upon this, courting inquiry as I wish to do, I wrote to Dr. Glover, offering him an inspection of our brewery and stores, in any way he thought proper; and also (adopting a suggestion of the late Lord Tenterden, in the case of the *Burton Brewers v. the Society for the Diffusion of Knowledge*, in 1830), I put my head brewer in communication with him. The answer I received from Dr. Glover was, I must say, not quite so satisfactory as I could have wished, inasmuch as I considered that, as he had lent himself to fan the prejudice,

it was but fair he should assist in putting the matter right as publicly as he had aided the mischief.

Dr. Glover appears to be dissatisfied with my publication of a portion of his letter, of which, by-the-bye, I have made no exclusive use, giving it as a testimony in favour of all pale ales, as well as my own. But Dr. Glover, though expressing to me a modification—which rendered it harmless—appeared unwilling to give the same publicity to the explanation as he had volunteered to the charge. I could, therefore, regard him only in the light of a public accuser, to be defeated by the weapons with which he had himself supplied me; and the public, I thought, might be the better convinced by seeing how the doctors, whose curious learning was frightening them from drinking pale ale, could find no objection to enjoying it themselves.

If, however, there were any impropriety in the publication of Dr. Glover's good opinion in the first instance, it is now quite removed, by the permission he has now given me to that effect, with the explanation, that he had not originally meant it for publication, and that the sentence quoted is not such as he would have written in a letter intended for publicity. That you, sir, and the public may form an opinion how far I have compromised Dr. Glover, I beg (with his permission) to enclose you the letter, the publication of which, *in extenso*, will, I trust, do full justice both to Dr. Glover and myself.

Dr. Glover to Mr. Allsopp.

"Newcastle-on-Tyne, April 11.

Sir,—It was not my intention, in writing the hasty note to the *Lancet*, to cast any reflections upon, or to implicate, in any way, respectable brewers of pale ale.

When I first saw the statement about the alleged use of strychnine in bittering ale, I looked upon the assertion as incredible, both on account of the price of the drug and the symptoms it would create; but, on experiment, I found that strychnine possesses such wonderful bitterness, that it might perhaps be used as an adjuvant, at least by UNPRINCIPLED PERSONS. In short, my object was simply to show that the thing was not altogether so impossible as it appeared at first sight to be.

My own opinion is, that hops should not enjoy the exclusive privilege of being used for bittering beer; but I do not pretend to discuss the point with practical men.

I know there are bitters which might be used beneficially, in a medical point of view.

With regard to analysing your beer, my time is taken up, so far as analysing and chemistry are concerned, with two kinds of inquiries—1st, those which are purely scientific; and 2nd, those which are profitable. If you wish me, in the latter capacity, to analyse and report on your beer, I, of course, can have no objection.

I have to prepare for an absence of three or four days to-morrow, and so beg you to excuse me replying to the letter of Mr. Bottinger, for which I am much obliged.

Yours, &c.,

(Signed) H. M. GLOVER.

H. Allsopp, Esq.

P.S.—I presume you will hardly expect me to write to the *Lancet*. However, I shall be at home on Thursday evening, and most assuredly I have no desire to say anything which could weaken the confidence of the public in your beer. But that I am not now in the habit of drinking bitter beer, I should be glad to show my confidence by drinking plenty of it.

I consider any further observation unnecessary, save that I inserted Dr. Glover's good-natured remark on my bitter beer as an "incidental testimonial," and no more. I never called it "a certificate;" nor did I apply to him, or any other medical gentleman, for one. I am not responsible that such a construction has been placed upon the off-hand expressions of good opinion which have been sent to me from all quarters; and I have only to express my regret to Dr. Glover, that he has been exposed to an imputation so unfounded.

I am, &c.,

HENRY ALLSOPP.

Brewery, Burton-on-Trent, Sept. 22, 1852.

## RECOVERY OF FEES FROM DECEASED PATIENTS' FRIENDS.

AN action of great importance to the medical profession was lately brought in the Brompton County Court, whereby the practicability of recovering their fees after the decease of patients was shown, and also the necessity of their fairly understanding to whom they are to look for payment in the event of death. The plaintiff, Mr. Ince, is a surgeon residing in Pimlico, and the defendant is an elderly lady named Spencer, sued in her capacity of executrix to her deceased mother, who was indebted to plaintiff the sum of £13 2s. 6d. An objection was taken to the summons by defendant's solicitor, on the ground that Miss Spencer was not an executrix, her mother leaving nothing to administer to. Mr. Ince said the defendant called upon him, and asked him to visit her mother, who was lying dangerously ill. He attended her, and about twelve months afterwards he was requested to send in his bill instantly by Miss Spencer. Knowing them to be respectable people, he did not do so until Christmas, the usual time for medical men to send in their accounts. After this he waited some time, and sent a note. No notice being taken of this, he sent a person for the account, who brought word back that defendant's mother had previously paid witness £10 of the account. Mr. Ince then called, and Miss Spencer told him the same tale, and said she would not pay twice over. He asked her to produce some receipt or evidence of his having been paid. This defendant could not do, and offered to pay the balance of £10 if he would give a receipt in full. Defendant also denied that her mother had left any property. He pointed out several pieces of furniture to Miss Spencer, and remarked to her that they were surely her mother's property. Can positively swear he never received one penny from the deceased or defendant. The furniture in defendant's house is worth £300 or £400.

Miss Spencer examined by Mr. Roberts. I am perfectly convinced that the plaintiff's account has been partly paid; I searched the house for the receipt, but in consequence of having burned all my mother's papers, it could not be found; my mother did not leave a vestige of property, and I have not taken out letters of administration; the expenses of the funeral were paid by me partly out of an annuity of my mother's; it was not by my wish Mr. Ince attended my mother, and I merely acted up to my mother's instructions in telling him my mother wished to see him.

By Mr. Jones. My mother left about ten sovereigns; she had no other property; the furniture in the house was all mine; I purchased it out of the produce of my school; I purchased the house for about £400 out of my savings; my mother told me she was going out to pay Mr. Ince, and I am certain she paid him £10.

The Judge said: There is no evidence as to defendant being executrix. But that I will amend. As to plaintiff having been paid, there is not a title of evidence, and I believe his statement to be true. I consider plaintiff is entitled to a verdict, on the ground of defendant having herself employed him. Verdict for plaintiff, and costs.

M. W. HANLON, M.B.

OBITUARY.—October 10th, at Roseborough, near Naas, in the 67th year of his age, Samuel Hall, M.D.

**STUDENTS' NUMBER OF THE MEDICAL PRESS.**

THE STUDENTS' NUMBER will be published on WEDNESDAY, the 27th of October. Regulations of Colleges and other Institutions for Medical and Surgical Education, properly authenticated, should be transmitted to our Office *without delay*, in order to secure a careful analysis of them. Advertisements of Lectures and Hospitals, Books, Surgical Instruments, and Medicines, not later than the 23rd.

**CITY OF DUBLIN HOSPITAL.**

UPPER BAGGOT-STREET.

The Winter Session will commence on Monday, the 25th of October.

The arrangements of this hospital are such as to afford the student an opportunity of studying disease in all its forms—medical and surgical. The morning visit commences daily at half-past eight o'clock, when the nature, treatment, and progress of each case are explained at the bedside of the patient, and ample opportunity afforded to every pupil of becoming practically acquainted with the uses of the stethoscope. Clinical lectures are also delivered after the hospital visit.

Connected with the hospital is an extensive dispensary, at which the pupils are allowed to perform the minor operations, under the guidance of the surgeons, and are rendered familiar with the details of dispensary management.

Every facility is given to students desirous of acting as dressers and clinical assistants, subsequent to which all pupils of the hospital are eligible to the situation of house-surgeon, according to merit.

A distinct course of Lectures upon Diseases of the Eye is delivered by Dr. Jacob, which the pupils are privileged to attend without additional fee, and special wards are appropriated for the reception of eye cases. Extended opportunities are thus afforded thus afforded for acquiring a thoroughly practical knowledge of this important subject.

A ward is appropriated to the Diseases of Females, and clinical instruction is given upon all forms of uterine affection by Dr. Beatty.

Mr. Tufnell's course of Lectures upon Military Surgery is also open to the pupils of the hospital. This course is recognized as equivalent to six months' surgery in the professional qualification of candidates for admission into the army, navy, and ordnance medical departments, and is required to be attended by all gentlemen entering the Hon. East India Company's Service.

A lending library of well chosen books has been provided for the use of the pupils; and a correct registry of the cases in hospital is kept by the house-surgeon, to which they have free access.

Certificates of attendance on this hospital are recognized by all the colleges, universities, and halls, and by the army and navy medical boards.

Fee for	Winter six months	...	...	Six guineas.
"	Summer six months	...	...	Four guineas.
"	Nine months	...	...	Eight guineas.

*Medical Attendants.*

- A. Jacob, M.D., Fellow and Professor of Anatomy and Physiology, Royal College of Surgeons, 23, Ely-place.
- T. E. Beatty, M.D., Fellow and Professor of Midwifery, Royal College of Surgeons, 18, Merrion-square, North.
- C. Benson, M.D., Fellow and Professor of the Practice of Medicine, Royal College of Surgeons, 34, York-street.
- W. Hargrave, M.D., Fellow and Professor of Surgery, Royal College of Surgeons, 37, York-street.
- R. C. Williams, M.D., Fellow and Professor of Materia Medica, Royal College of Surgeons, 14, Lower Fitzwilliam-street.
- T. G. Geoghegan, M.D., Fellow and Professor of Forensic Medicine, Royal College of Surgeons, 52, York-street.
- J. Tufnell, Esq., Fellow of the Royal College of Surgeons, 58, Lower Mount-street.

*Consulting Physicians*

Sir Henry Marsh, Bart., and Professor Apjohn.

*Consulting Surgeons.*

Sir Philip Crampton, Bart., Professor Porter, and J. W. Cusack, M.D.

\* \* For further particulars apply to Dr. Benson, 34, York-street.

**ROYAL COLLEGE OF SURGEONS IN IRELAND.****SCHOOL OF SURGERY.**

WINTER SESSION 1852-53.

THE Dissecting-rooms opened on the 1st of October, and the Lectures will commence on the 25th.

Anatomy and Physiology—Dr. Jacob.  
 Descriptive Anatomy—Dr. Hart and Dr. Power.  
 Surgery—Mr. Porter and Mr. Hargrave.  
 Practice of Medicine—Dr. Benson.  
 Chemistry—Dr. Barker.  
 Midwifery—Dr. Beatty.  
 Comparative Anatomy—Dr. Jacob.  
 Dissections by the Professors of Anatomy and the Demonstrators—Dr. Leeson, Mr. T. D. Hargrave, Mr. Malcomson, and Mr. J. Morgan.

**SUMMER SESSION.**

Materia Medica—Mr. Williams.  
 Botany—Dr. A. Mitchell.  
 Medical Jurisprudence—Dr. Geoghegan.  
 Practical Chemistry—Dr. Barker.

*The Fee for each of the above Courses is Two Guineas.*

For further information apply to any of the Professors, or to the Registrar.

By order,

W. BOYLAN, Registrar.

**DETAILS OF THE EYE.**

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

**NEW EDITION OF ELLIS'S ANATOMY.**

This day, Third Edition, small 8vo, 12s. 6d., cloth, DEMONSTRATIONS OF ANATOMY: a Guide to the Knowledge of the Human Body by Dissection.

By GEORGE VINER ELLIS,

Professor of Anatomy in University College, London.

London: Taylor, Walton, and Maberly, 28, Upper Gower-street, and 27, Ivy-lane.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

*Superior Dissecting Instruments well worth the inspection of the Student.*

**THE COMPOUNDING DEPARTMENT AT G. O. AND CO.'S MEDICAL ESTABLISHMENT**

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

**BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.**

G. O. and Co. continue to be supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

The Royal College of Surgeons in Ireland grants two different Diplomas—one conferring the rank of Fellow, and the other that of Licentiate. The Fellow is a member of the corporation, and entitled to vote at all elections for president, vice-president, and councillors, and also to be elected president, vice-president, or member of council. The Letters Testimonial granted to the Licentiate enables him "to exercise and enjoy all rights of practice in the art or science of surgery, or otherwise, which are commonly enjoyed by the Fellows, and to have free access to the library and museum of the College, and makes him eligible to the rank of Fellow, subject to specified regulations." Both Fellows and Licentiates are obliged to make and subscribe a formal declaration legally binding them "to observe and be obedient to the statutes, by-laws, and ordinances of the College, and to the utmost of their power to promote its honour, reputation, and dignity." Fellows,

in addition, declare that they "do not practise the business or profession of an apothecary or druggist, or indirectly sell drugs or medicines, and that they will not, while Fellows, practise such business or profession."

A student who proposes to become a Fellow or Licentiate of the College must first become a Registered Pupil, for which he pays a fee of five guineas; but he is permitted to postpone such entry as Registered Pupil, and such payment, until the period of his final examination.

The fees for the Diplomas are as follows:—For Fellowship, twenty-five guineas, in addition to the registration fee of five guineas; thirty guineas in all. But if the candidate has already passed as a Licentiate, and paid the registration fee of five guineas, and twenty guineas, the fee for Letters Testimonial—twenty-five in all; he is required to pay a Fellowship fee of ten guineas only, should he propose to become a Fellow. If a person becomes a Fellow at once, he pays thirty guineas; but if he commences as Licentiate and afterwards passes as Fellow, he pays thirty-five guineas in all—viz., five guineas registration fee, twenty guineas for Letters Testimonial, and ten guineas for Fellowship. For the Licence or Letters Testimonial alone, the candidate pays five guineas registration fee, and twenty guineas for the final examination—twenty-five in all. The student who becomes a Registered Pupil as soon as he commences his studies in Dublin, is thereby matriculated in the College, and entitled to its protection, aid, and guidance. Fellows of the College who settle to practise in Dublin, are required to pay ten guineas in addition to their other fees.

*Fellowship.*—The candidate for the Fellowship must be twenty-five years of age, and if not a Graduate in Arts of some university, must be prepared to answer a classical examination, which is generally confined to the principal books read for entrance into Dublin University. He must have been six years engaged in professional study, three of which must have been in Dublin; and he must also have been a house-surgeon or dresser in an hospital. He is required to attend lectures on anatomy and physiology, and on surgery with dissections during three seasons, che-

mistry during two, and practice of medicine, materia medica, midwifery, medical jurisprudence, comparative anatomy, natural philosophy, and botany, for one course each. His hospital attendance must be three years at least. Bachelors of Arts, after five years' study, are admitted to examination on compliance with the above regulations; and Licentiates of the College of ten years' standing are also admitted, although they may not have been educated in strict conformity with them.

*Letters Testimonial.*—The candidate for Letters Testimonial is required, as has been already stated, to become a Registered Pupil, and to pass a classical examination. He is also required to prove that he has studied for three years in the metropolitan schools (nine months in each year), and for a fourth year either there or anywhere else, where he might have obtained professional information. His hospital attendance is by the by-law declared to be three years "where clinical instruction is given," and all the Dublin hospitals are recognized. Credit is given for attendance on provincial hospitals, but it is expected that while the pupil is in attendance on lectures in Dublin, he shall, at the same time, attend an hospital there. Candidates for Letters Testimonial are also required to prove that they have attended three courses of lectures on anatomy and physiology, surgery, and practical anatomy (being demonstrations with dissections), two courses on chemistry, and one course on the practice of medicine, materia medica, midwifery, and medical jurisprudence.

Candidates both for the Fellowship and Letters Testimonial are examined on the *practice of medicine and pharmacy* as well as on surgery. The Diploma is a full qualification as General Practitioner, entitling the holder of it to be appointed to county infirmaries, fever hospitals, dispensaries, poorhouses, and all other medical charities. They can also practise medicine as fully and freely as Doctors of Medicine, or Fellows or Licentiates of Colleges of Physicians; and *Licentiates* of the College can dispense medicines to their own patients; but they cannot keep open shops, or retail drugs, or compound the prescriptions of other practitioners without the licence of the Apothecaries' Company. Both Fellows and Licentiates are authorized by law, and permitted by the charter, to compound and dispense medicines for their patients in the hospitals, dispensaries, and poorhouses to which they are attached. None but Fellows and Licentiates of this College are eligible to be appointed Surgeons of County Infirmaries in Ireland.

The College of Surgeons of Ireland is empowered by charter to grant a diploma in midwifery to its own Fellows and Licentiates only; and does not recognize any of them as midwifery practitioners, or mark them as such in the printed lists of the College, unless they have had that diploma granted to them.

Certificates granted by Professors in universities which do not receive the certificates granted by the Professors in the College of Surgeons, are not recognized as qualifications from candidates for either of the diplomas.

Returns of the names of those who have entered to attend lectures, are required to be forwarded to the College, by Professors and Lecturers, on the 25th of November, and at such other periods during the session as the Council may think fit; which returns must certify that the students named therein are then attending regularly; and no certificate is received from any candidate for either of the diplomas unless his name appears in the returns corresponding to the date of such certificate. Professors or Lecturers neglecting or refusing to make such returns, or who grant certificates to any student whose name has not been inserted in such returns, are not recognized.

Students are admitted to the classical examination required by the by-laws without being required to become Registered Pupils, or to pay the registration fee of five guineas; it being considered desirable that pupils on their

first arrival in Dublin, and as soon as they can conveniently do so after leaving school, should pass this preliminary trial, and not postpone it until the period of their final examination for Letters Testimonial. They have only to present themselves at the College, and to pay a fee of five shillings to enable them to offer themselves; and if approved, the certificate required by the by-laws to be produced by candidates for Letters Testimonial is granted to them. On payment of five guineas at any subsequent period, they are enrolled as Registered Pupils, and become entitled to study in the museum and library, and to attend the lectures on comparative anatomy. They are examined in the Gospel of St. John in the Greek Testament, and in the first five books of the *Æneid* of Virgil. The following Ordinance of Council was made April 9, 1851:—

"To enable surgical students to devote more time to hospital attendance and dissection during the winter session, the lectures on materia medica, medical jurisprudence, practical chemistry, and botany, shall be delivered during the summer session in the School of the College, and in the Schools recognized by the College. To secure due attendance on hospital practice by the student for the full term required by the by-laws, certificates of such attendance during the summer session shall be granted separately from those granted for the winter session. Certificates granted subsequent to the 30th of April, 1851, shall not be received as qualification for Letters Testimonial unless issued in conformity with these regulations."

On the 4th of December, 1850, the Council of the College adopted the following resolution with reference to the by-law which enjoins that "certificates shall not be received from teachers or professors in colleges or other institutions which refuse to receive the certificates of Professors in the College of Surgeons":—

"The Council being anxious to encourage liberal education among candidates for Fellowships and Letters Testimonial, in future all *Graduates in Arts* of the University of Dublin, being Registered Pupils of the College of Surgeons, shall be admitted to the examinations for Fellowship and Letters Testimonial, provided they produce the certificates of surgical education required by the by-laws, and of such course of education the several certificates of the School of Physic, now required by the 'Regulations of the University to be produced by candidates for the degree of Bachelor of Medicine, shall be received as part.'"

The Board of Trinity College not having reciprocated to this resolution in accordance with the terms of the by-law (notwithstanding its adoption at their suggestion), Bachelors of Arts, being Licentiates of the College of Surgeons, may be disabled from availing themselves of the advantages it offers, when seeking the degree of Bachelor of Medicine.

The following are the educational by-laws in detail:—

#### 1. *Registration of Pupils.*

Every person requiring to be registered as a pupil on the College books, shall, if the Council think fit, be so registered, if he shall have laid before the Council a receipt, showing that he has lodged, to the credit of the College, in the Bank of Ireland, a registry fee of five guineas. Registered Pupils are admitted to the classical examination at the time of registry, or at any time previous to the final examination for Letters Testimonial. Students, not being Registered Pupils, are admitted to the same examination on payment of five shillings.

#### 2. *Qualifications of Candidates for Letters Testimonial.*

Every Registered Pupil shall be admitted to an examination for Letters Testimonial, if he shall have laid before the Council the following documents:—*a.* A receipt, showing that he has lodged a sum of twenty guineas in the Bank of Ireland, to the credit of the President, and for the use of the College. *b.* A certificate from the examiners of the College that he has passed an examination as to his acquaint-

ance with the Greek and Latin languages. *c.* Certificates showing that he has been engaged in the study of his profession for not less than *four years*; *three* of which shall have been passed in attendance on lectures or hospitals in Dublin, London, Edinburgh, or Glasgow. *d.* Certificates of attendance on a hospital recognized by the Council, where clinical instruction is given, during three years. [An attendance of nine months in each year is accepted.] *e.* Certificates of attendance on *three* courses of lectures on anatomy and physiology, *three* courses of lectures on the theory and practice of surgery, and of the performance of *three* courses of dissections, accompanied by demonstrations; also certificates of attendance on *two* courses of lectures on chemistry; or one course of lectures on general, and one on practical chemistry; one course of lectures on *materia medica*; one course of lectures on the practice of medicine; one course of lectures on midwifery; and one course of lectures on medical jurisprudence.

### 3. Examination of Candidates for Letters Testimonial.

The examinations of candidates for Letters Testimonial shall be held from time to time, as the Council may direct. Five examiners at least shall be present at each examination. Each candidate shall be examined upon anatomy, physiology, the theory and practice of medicine and surgery, *materia medica*, and the form of prescription; and shall perform such surgical operations or dissections, or explain such anatomical and pathological preparations as the examiners may require. Candidates whose answering shall be found insufficient will not be allowed to present themselves a second time until after the expiration of six months from their first examination.

### 4. Qualifications of Candidates for the Fellowship.

Every Registered Pupil or Licentiate shall be admitted to examination for the Fellowship if he shall have laid before the Council the following documents:—*a.* A receipt, showing that he has lodged in the Bank of Ireland, for the use of the College, the sum of *ten guineas*, in case he is a Licentiate, or of *twenty-five guineas*, in case he is a Registered Pupil; provided, in either case, he intends to reside beyond ten miles from Dublin. [Should the candidate intend to reside in Dublin, or within ten miles thereof, he shall lodge, if he is a Licentiate, twenty guineas; or if he is a Registered Pupil, thirty-five guineas. Fellows entering on the country list, who may subsequently settle as practitioners in Dublin, or within ten miles thereof, shall pay ten guineas to the College.] *b.* A certificate that he is twenty-five years of age. *c.* A certificate that he is a Bachelor of Arts of some university, or that he has been examined in such manner as the Council may, from time to time, direct, with a view to ascertain that he has obtained a liberal preliminary education. *d.* A certificate, signed by two or more Fellows of the College, of good general conduct during his professional education. *e.* Certificates that he has been engaged in the acquisition of professional knowledge for a period of not less than *six* years, during three of which he must have studied in one or more of the schools and hospitals of Dublin recognized by the Council. He may have studied for the other three years in any school or schools of the united kingdom, which shall be approved by the Council, or in any foreign school of repute. It is also required that the candidate shall have had opportunities of practical instruction, as house-surgeon or dresser, in a recognized hospital. *f.* Certificates of attendance on the several courses of lectures required to be attended by candidates for Letters Testimonial, together with one course of lectures on comparative anatomy, one course of lectures on botany, and one on natural philosophy. *g.* A thesis on some medical subject; or clinical reports, with observations of six or more medical or surgical cases taken by himself. *h.* Candidates of the required age, who shall have taken the degree of Bachelor of Arts in a British or Irish University, and have complied with the foregoing regulations in other respects, will be admitted to examination at the end of five years of professional study; of which three years must have been passed in one or more of the recognized schools or hospitals of Dublin. *i.* Licen-

tiates of the College, who may not be able to show that they have followed the course of study specified in the preceding regulations, may, at the expiration of ten years from the date of their diploma, be admitted to the examination required for the Fellowship, provided they produce such evidence as shall be satisfactory to the Council that they have conducted themselves honourably in the practice of their profession.

### 5. Qualifications of Candidates for the Diploma in Midwifery.

Any Fellow or Licentiate of the College shall be admitted to an examination for the diploma in midwifery, upon laying before the Council the following documents:—*a.* A certificate, showing that he has attended one course of lectures on midwifery and diseases of women and children, delivered by a professor or lecturer in some school of medicine or surgery recognized by the Council. *b.* A certificate, showing that he has attended the practice of lying-in hospital, recognized by the Council, for a period of six months; or the practice of a dispensary for lying-in women and children, recognized by the Council, and devoted to this branch of surgery alone. *c.* A certificate showing that he has conducted thirty labour cases at least. Candidates for the midwifery diploma shall be publicly examined on the organization of the female; the growth and peculiarities of the fœtus; the practice of midwifery; and the diseases of women and children; and if approved of, shall receive a licence or diploma certifying the same.

### 6. Regulation of Schools.

Certificates shall not be received for attendance on lectures delivered in Ireland, unless from teachers in schools permitting the visitation of the Council, and receiving their sanction. Neither shall certificates be received from teachers or professors in colleges, or other institutions for medical or surgical education, in Great Britain or Ireland, which colleges or institutions refuse to receive, as qualifications for a degree or licence, the certificates issued by Professors in the College of Surgeons; nor shall certificates be received from teachers who deliver lectures upon more than one distinct subject, as hitherto allotted to professors in colleges and universities. This regulation shall not, however, exclude the certificates of two or more teachers, who may deliver conjointly, separate, perfect, and distinct courses on anatomy and physiology, and on the theory and practice of surgery.

Certificates shall not be received for attendance on lectures on anatomy and physiology, unless such lectures shall have been delivered upon at least five days of each week of the usual *winter* season, between October and May, nor on the theory and practice of surgery, unless delivered within the *same* period, on at least three days in each week.

The courses of lectures on the practice of medicine, chemistry, *materia medica*, midwifery, and medical jurisprudence, shall consist of sixty lectures at least,\* and the courses of dissections and demonstrations shall be of six months' duration.

Certificates shall not hereafter be received for attendance on lectures delivered in Ireland, unless from persons who shall have acquired, either by education or practice, such ample information, on professional subjects generally, as is required from candidates for the Fellowship of the College, and who shall have enjoyed such opportunities of acquiring information on the particular subjects upon which they propose to lecture, as the Council may consider necessary to qualify them to perform that duty.

### Returns of Students attending Lectures.

Professors and Lecturers are required to transmit to the College on or before the 25th day of November in each year returns of the names of the pupils who shall have entered to attend, and are then actually attending their respective lectures or demonstrations. They are also required to ascertain, from time to time, whether the students so returned are in attendance or not, as similar returns are required in the course of the session.

\* The summer courses on these subjects are recognized.

Dwyer, F. Churchill.

*Inspectors of Apothecaries' Shops*—T. Brady, A. Smith,  
J. F. Duncan, W. E. Steele.*Regulations respecting the Education, Examination, and  
Admission of Candidates for the Licence to Practise  
Medicine.*Candidates for the Licence of the College to Practise  
Medicine, are required to make application to the College,  
according to the forms supplied by the Registrar.Every application for admission to examination, on being  
received and read at one meeting of the College, will, at  
the next meeting, be taken into consideration.No member or Licentiate of any company of apothecaries  
is admissible to the licence of the College, unless, on  
being examined and approved of, he shall surrender to the  
College his licence as an apothecary, and cease to act as  
such in any part of the united kingdom.Every candidate for the licence of the College, except  
those who have entered as Students in Arts in the Univer-  
sities of Dublin, Oxford, or Cambridge, is required to pro-  
duce a certificate of matriculation in the University of Dub-  
lin, conformably to the statute, 40 Geo. III., c. 84, s. 34.Candidates must produce evidence of having been en-  
gaged in the study of medicine for four years at least, and  
of having attended not less than two of the required courses  
in each year.Candidates must produce evidence of having completed  
the following course of education—viz., of having attended  
one or more courses of lectures on each of the following  
subjects for the periods specified:—Anatomy and phy-  
siology; chemistry; institutes of medicine; materia me-  
dica and pharmacy; practice of medicine; midwifery, and  
diseases of women and children; surgery—six months  
each; botany and medical jurisprudence, three months  
each; of having performed a course of dissections and at-  
tended the accompanying demonstrations during six months;  
and of having attended a course of practical chemistry for  
at least three months.All the lectures are required to have been delivered by  
the respective professors of the School of Physic in Ireland,  
or by other lecturers recognized by the College.Candidates must also produce certificates of attendance  
for two years and six months on the practice of a recog-  
nized hospital, and the clinical lectures delivered therein  
during that period; also for six months on the practice of  
a lying-in hospital recognized by the College.The foregoing regulations apply to all candidates ex-  
cept—1st, Graduates in medicine (not honorary) of one  
of the universities in the united kingdom; 2nd, Licen-  
tates of the Royal Colleges of Physicians of London or  
Edinburgh; 3rd, Officers holding medical or surgical com-  
missions in her Majesty's service; 4th, Licentiates of a  
college of surgeons in the united kingdom of four years'  
standing; 5th, Licentiates of a college of surgeons in the  
united kingdom, producing, in addition to their diploma  
as such, certificates of attendance on a course of lectures  
on the institutes of medicine and botany, and on the prac-  
tice of a lying-in hospital for six months; candidates are  
admissible to examination on producing evidence of their  
possessing any of the foregoing qualifications, in addition to  
the certificate of matriculation in the University of Dublin.On having obtained permission to be examined for the  
licence, the candidate is required to present himself before  
the College within three months.

The President appoints the day for the examination of

the candidate, but not until the admission fee, and the  
stamp duty, have been lodged with the Treasurer of the  
College; which sums, in the event of the candidate not  
being admitted, will be returned.Every candidate, previously to examination, is required  
to sign the following declaration:—"I, A. B., hereby  
authorize the President and Fellows of the King and Queen's  
College of Physicians in Ireland, to erase my name from  
the list of Licentiates, and I consent to surrender my licence,  
and to have my privileges as a Licentiate withdrawn,  
if I shall, after having obtained the licence from said Col-  
lege, either continue to be or become a Licentiate of any  
company of apothecaries; or if I shall at any time hold  
or have any interest in an apothecary's shop, or engage in  
any trade in any part of the united kingdom."The President and Censors examine the candidate pub-  
licly before the Fellows and Licentiates of the College.The examinations are conducted in the English language;  
but every candidate, except Graduates in Arts of Dublin,  
Oxford, or Cambridge, may be required, at the option of  
the President, to translate from a Latin or Greek medical  
author, before being examined as to his professional  
acquirements.The examination of candidates for the licence of the  
College to practise medicine is conducted on two sepa-  
rate days;—the subjects of examination for the first day  
are anatomy and physiology, botany, chemistry, and ma-  
teria medica and pharmacy; for the second day, acute dis-  
eases, chronic diseases, the institutes of medicine, and mid-  
wifery.Candidates who are Graduates in Medicine of one of the  
Universities in Great Britain or Ireland; Licentiates of  
either of the Royal Colleges of Physicians, London or  
Edinburgh; or Members of a Royal College of Surgeons in  
the united kingdom, being also Graduates in Arts of the  
Universities of Dublin, Oxford, or Cambridge, are required  
to undergo the second day's examination alone—botany  
and materia medica in the case of members of a College of  
Surgeons being added thereto.Should the College not be satisfied with the answering  
of any candidate, they may repeat the examination of either  
day after the lapse of not less than two months.Every candidate, previously to his being admitted as a  
Licentiate of the College, is required to subscribe and prom-  
ise the due fulfilment of the following declaration—viz.:  
"I, A. B., do hereby solemnly and sincerely promise that  
I will observe the statutes and by-laws of this College, and  
to my power endeavour that the honour of the College be  
preserved entire; and in all things that belong to the  
honour or profit thereof, I shall be ready to give my ad-  
vice and assistance. I engage not to practise any system  
or method (so called), for the cure or alleviation of disease  
of which the College has disapproved; nor to endeavour to  
obtain practice or to attract public notice by advertising,  
or by any other unworthy means: I also engage that I  
will neither permit nor sanction the use of my name by  
any other party for such purposes, nor in connexion with  
any secret or other remedy; and in case of any doubt rela-  
tive to the true meaning or application of this engagement,  
I promise to submit to the judgment of the College. I  
promise that in all things lawful and honest, I will be obe-  
dient to the president, vice-president, and censors of the  
College. And I solemnly and sincerely declare, that should  
I violate any of the conditions enumerated in this declara-  
tion, so long as I shall be either a Licentiate or Fellow of  
the College, I thereby render myself liable, and shall sub-  
mit to any reasonable punishment, whether censure of the  
College, pecuniary fine (not exceeding twenty pounds), or  
expulsion and surrendering of the licence, whichever the  
President and Fellows of the College, or the majority of  
them, shall think proper to inflict."The President then admits the candidate to the licence  
of the College, authorizing him to practise medicine.Fee for the licence to practise medicine, exclusive of the  
stamp duty, £30.Every member of this College who may desire to obtain  
the licence to practise midwifery is required to produce a

certificate of attendance for six months on the practice of a recognized lying-in hospital, when the College will proceed to examine him as to his knowledge of midwifery, and if approved of, will grant him a special licence as a practitioner in midwifery, and cause him to be designated as such in the authorized lists of the College.

The by-laws relative to the examination and admission of candidates for the licence to practise medicine shall, so far as they may be applicable, also regulate the examination and admission of candidates for the licence to practise midwifery. The fee payable to the College for the licence to practise midwifery shall be one guinea.

The following shall be the form of the Diploma to be granted to every person examined and admitted by the College to practise midwifery:—"We, the President and Fellows of the King and Queen's College of Physicians in Ireland, in pursuance of the powers vested in us by Royal Charter, having duly examined \_\_\_\_\_ in the Theory and Practice of Midwifery and the Diseases peculiar to Women, and having found him well skilled in those branches of Medicine, hereby certify him to be fully qualified to practise therein. In testimony whereof, we have hereunto subscribed our names and affixed our common Seal. Dublin, dated this \_\_\_\_\_ day of \_\_\_\_\_ 185 \_\_\_\_."

W. E. STEELE, M.B., Registrar.

#### REGULATIONS RESPECTING THE TAKING OF MEDICAL DEGREES IN TRINITY COLLEGE, DUBLIN.

By the Statutes or Rules of Dublin University, entitled, "Consuetudines sue Regulæ pro Solenniori Graduum Collatione," first published in 1778, but enacted long before that period, the method of taking Medical Degrees, and the terms upon which they are to be granted, are laid down; and as these Rules are still in force, having never been repealed, Degrees in accordance with their provisions are given as heretofore. These are the Degrees which have been taken by the present Bachelors and Doctors of Medicine of Trinity College in practice; but within the last few years a Degree of a different description has been granted to some, the legal and academic value of which does not appear to be defined. The following are the Rules for taking the regular Degrees:—

##### *"Of taking Degrees in Physic."*

No one shall be admitted to the degree of Bachelor in Physic who has not first taken the degree of Bachelor in Arts, and who has not completed three years (reckoning from the day of his admission to the degree of Bachelor in Arts). Whoever applies for the degree of Bachelor in Physic, shall, before he is proposed for the grace of the College, solemnly in the public hall perform the part once of respondent and once of opponent in two questions of physic, from one of the clock in the afternoon to three: he shall moreover solemnly and publicly prelect twice on two several days. No one shall be admitted to the degree of Doctor in Physic who has not completed five years in the study of physic from the time of his being admitted Bachelor; and who shall not publicly and solemnly prelect four times on four several days, from one of the clock in the afternoon to two: in which prelections he shall explain some part of Hippocrates or Galen, and shall moreover in the public hall solemnly perform the part once of respondent and once of opponent, in two questions in physic, from one of the clock in the afternoon to three.

##### *Form of supplicating for Degree of Bachelor in Physic.*

This degree may be applied for after three several manners:—1st, whoever begins the study of physic immediately on his admission into the College by matriculation, may apply for his degree after the completion of twenty-four terms; 2ndly, if he begins from his being admitted Bachelor of Arts, then after three years; 3rdly, if from the time of commencing master, then after two years.

##### *The Form for the first Manner.*

Right Rev. the Vice-Chancellor, and the whole University, N. N. prays your reverences that twenty-four terms completed in the study of physic, from his matriculation, together with all exercises required by the laws and customs of the College, may be sufficient for him to answer a question in physic.

##### *For the second Manner.*

That three years, from his commencing Bachelor, completed in the study of physic, &c., as above.

##### *For the third Manner.*

That two years, from his commencing Master, completed in the study of physic, &c., as above.

##### *For the Degree of Doctor in Physic.*

The degree of Doctor in Physic may also be applied for three several ways, according to the different manners of applying for the degree of Bachelor:—1st, six years being completed from his Bachelor's Degree in said faculty, which was taken after twenty-four terms, or six years from his matriculation; 2ndly, five years being completed from his Bachelor's Degree, which was taken, having been before admitted Bachelor of Arts; 3rdly, four years being completed from his Bachelor's Degree, which was taken, having been before admitted Master of Arts.

##### *The Form for the first Manner.*

Right Rev. the Vice-Chancellor, and the whole University, N. N. prays your reverences, that six years completed in the study of physic, from his Bachelor's Degree, which was taken after twenty-four terms, or six years from his matriculation, together with all exercises required by the laws and customs of the College, may be sufficient for him to begin in physic.

##### *For the second Manner.*

That five years completed in the study of physic, from his Bachelor's Degree, which was taken, having been before admitted Bachelor of Arts, &c.

##### *For the third Manner.*

That four years completed from his degree of Bachelor in Physic, which was taken, having been before admitted Master of Arts, &c.

##### *The Form of Presentation.*

Right Rev. the Vice-Chancellor, and the whole University, I present to you these my sons, whom I know to be fit and qualified, both by their morals and learning, to be admitted to the degree of Doctor or Bachelor of Medicine; and this I testify and engage for on my faith to you and the whole College."

The following has been promulgated respecting the other degrees:—

"A candidate for the degree of Bachelor of Medicine must be a Graduate in Arts, and may obtain the degree of Bachelor of Medicine at the same commencement as that at which he received his degree of B.A., or at any subsequent commencement, provided the requisite medical education shall have been completed. The testimonium of the M.B. degree will contain the following certificate:—"Testatur A.B. sedulam operam medicinæ navasse, et examinationes coram professoribus feliciter sustinuisse." The medical education of a Bachelor of Medicine is of four years' duration, and comprises attendance on the following courses of lectures:—Anatomy and physiology, practical anatomy with anatomical demonstrations, surgery, chemistry, materia medica and pharmacy, institutes of medicine and pathology, practice of medicine, midwifery, botany, practical chemistry, medical jurisprudence, and also attendance on Sir Patrick Dun's Hospital during nine months, with three consecutive courses of clinical lectures, each of three months' duration, and also nine months' attendance on some general hospital in Dublin, approved of by the Board, in which clinical instruction in medicine and surgery is delivered.

A year's attendance, or an *annus medicus* in the School of Physic, may be kept in three ways:—1, by attending at least two, or not more than three, of the foregoing courses of lectures, which are of six months' duration;

2, by attending one course of six months' and two of three months' duration; 3, by nine months' attendance on Sir Patrick Dun's Hospital, and clinical lectures; together with one course of lectures of six months', or, in lieu thereof, two courses of three months' duration.

Three of these courses, at the discretion of the candidate, may be attended in the University of Edinburgh.

The course of practical anatomy and anatomical demonstrations does not count as a course of lectures.

Every pupil, before he be admitted to attend the clinical lectures, must pay the Professor £3 3s. for each three months' course of lectures, and shall enter his name with the Treasurer of Sir Patrick Dun's Hospital, and pay him *ten guineas*, unless he shall have been matriculated in the University of Dublin, or of Oxford, or of Cambridge, and shall have continued his studies in arts, under a tutor, in one of the said universities, for the space of *two years at least*, in which case he shall pay the sum of £3 3s. to such Treasurer, for the first half year, with a proportionate sum for any longer period.

The examination for the degree of Bachelor of Medicine is conducted by the Regius Professor of Medicine, the Professor of Surgery in the University, and the Professors of the School of Physic in Ireland.

A Doctor in Medicine must be M.B. of at least three years' standing, and must perform exercises for the degree before the Regius Professor of Physic, in accordance with the *rules and statutes* of the University. This degree entitles the holder to vote as a University elector, under the act 2 & 3 Wm. IV., c. 88, at all elections of members to represent the University in parliament.

The fees payable to the University for these degrees are as follow:—Bachelor of Medicine, £11 15s.; Doctor of Medicine, £22. In addition to these fees, the Stamp Act imposes a duty of £6 on each degree, and of £10 on the testimonium or certificate, under the College Seal, of the admission of any person to either degree."

As the document from which we copy this contains several erroneous statements, and suggests incorrect inferences respecting the Medical Department of Trinity College and the construction of the School of Physic, it becomes necessary to state that the only Professors of Trinity College who are Professors of the School of Physic, are the three following:—*Anatomy and Surgery, Chemistry, and Botany*. There is no Professor of Anatomy and Physiology in the University, neither is there any *Regius* Professor of Physic. Medical students, not in College, attending the lectures of the Medical Professors, are obliged to "matriculate;" that is, to pay a fee of five shillings, and to have their names entered on the College books, in order that they may be subjected to academic authority if they misconduct themselves, but they are not recognized as pupils of the University, or admitted to any examination or degree.

The following is the course of study to be pursued concurrently with the above medical exercises to obtain the degree of Bachelor of Medicine on four years' standing, arranged in Terms:—

**JUNIOR FRESHMEN. HILARY.—Mathematics.**—Elrington's Euclid, Books i. ii. Arithmetic.—The Theory of Fractions, Vulgar and Decimal; and the Doctrine of Proportion. *Greek*—Lucian, the Dialogues contained in Stock's Edition—viz., *Micyllus, Vitarum Auctio, Piscator, Prometheus*. *Latin*—Livy, Books iv. v. *Catechetical Examination*.—St. Luke's Gospel.

**TRINITY.—Mathematics.**—Euclid, Books i. ii. iii. Defs. Book v., and Book vi., omitting Props. 27, 28, 29. Arithmetic, as before. *Greek*—Stock's Demosthenes, vol. i. (Philippicæ i. ii., Olynthiacæ i. ii., and Oration de Pace). *Latin*—Cicero, Archias and Catiline. *Catechetical Examination*.—The Acts of the Apostles.

**MICHAELMAS.—Mathematics.**—Euclid, and Arithmetic, as before. Compendium of Algebra, and Geometry, to

end of Solution of Plane Triangles. *Greek*.—Stock's Demosthenes, vol. ii. (De Chersoneso, Philippicæ iii. iv. Literæ Philippi, in Philippi Epistolam). *Latin*.—Cicero against Catiline, i. ii. iii. iv. *Catechetical Examination*.—Archbishop Secker's Lectures on the Creed.

**SENIOR FRESHMEN. HILARY.—Mathematics.**—As before. *Logic*.—Walker's Edition of Murray. *Greek*.—Plato, Apology and Crito. *Latin*.—Cicero, de Amicitia and de Senectute. *Catechetical Examination*.—Genesis, and chapters i.-xx. of Exodus.

**TRINITY.—Mathematics.**—As before. *Logic*.—As before. Locke's Essay, Intr. and Books ii. and iii. (omitting in Book ii. sects. 10-20 of chap. i.; sects. 10 to end of chap. xiii.; chap. xv.; sects. 11-71 of chap. xxi.; chaps. xxx. and xxxii.; and chap. vi. of Book iii.) *Greek*.—Herodotus, Book i. *Latin*.—Tacitus, Germania and Agricola. *Catechetical Examination*.—Historical Books of the Old Testament, from Joshua to ii. Kings, both inclusive.

**MICHAELMAS.—Mathematics.**—As before. *Logic*.—Logic and Locke as before, with fourth Book of Locke. *Greek*.—Homer, Iliad, Books ix. xviii. xxiv. *Latin*.—Virgil, Georgics. *Catechetical Examination*.—Those parts of Isaiah, Jeremiah, Daniel, Micah, Zechariah, and Malachi, which are prophetic of the Messiah.

**JUNIOR SOPHISTERS. HILARY.—Logic and Locke.**—As before. *Physics*.—Hart's Mechanics, Part i. and chaps. i. ii. iii. of Part ii., omitting notes. *Greek*.—Sophocles, *Edipus Rex*. *Latin*.—Terence, *Adelphi* and *Hecyra*.

**TRINITY.—Logic and Locke.**—As before. *Physics*.—Hart's Mechanics, as before. Hart's Hydrostatics. Lloyd's Optics. *Greek*.—Euripides, *Medea*. *Latin*.—Juvenal, Sat. i. iii. iv. vii. viii. x. xiii. xiv.

**MICHAELMAS.—Logic and Locke.**—As before. *Physics*.—As before. *Astronomy*.—Brinkley, chaps. i.-viii. incl., xiv. xvi. xviii. *Greek*.—Æschylus, *Septem contra Thebas*. *Latin*.—Horace, Odes, Epodes, and Carmen Seclulare.

**SENIOR SOPHISTERS.**—In the Senior Sophister year there are five distinct courses, headed—Astronomy, ethics, mathematical physics, experimental physics, and classics, as given below. Students in general must answer in the courses headed astronomy and ethics, and in any two of the remaining courses which they may prefer. Students, however, who have credit for full attendance on the professional lectures in the School of Medicine, in any term, will, at the subsequent examination, be required to answer in *one* only of the three remaining courses, in addition to astronomy and ethics. At the degree examination no student can claim this privilege unless he has credit for full professional attendance for the actual year in which he presents himself for his degree.

**HILARY. Astronomy.**—As in Junior Sophister year. *Ethics*.—Stewart's Outlines of Philosophy. *Mathematical Physics*.—Mechanics, Hydrostatics, and Optics, as in Junior Sophister year. *Experimental Physics*.—Dixon on Heat, parts marked. Gregory's Outlines of Chemistry, 2nd Edit., vol. i., to p. 134. *Classics*.—Aristotle's Ethics, Books i. ii. iii. Cicero de Officiis, Book i.

**TRINITY.—Astronomy.**—As before. *Ethics*.—Stewart as before. Butler's Analogy, Part i., Introduction and chaps. iv. v., vii., and conclusion: Part ii., except chap. vii. *Mathematical Physics*.—As before. *Experimental Physics*.—Heat, as before. Roget on Electricity and Galvanism. Gregory's Outlines, remainder of vol. i. *Classics*.—Xenophon's Memorabilia, Books i. ii. Horace, Satires and Epistles.

**MICHAELMAS.—Astronomy.**—As before. *Ethics*.—Stewart and Butler, as before. Paley's Evidences, Part i. *Mathematical Physics*.—As before. *Experimental Physics*.—Heat and Electricity, as before. Chemistry, as before. Roget on Magnetism. *Classics*.—Thucydides, Book vii. Lucretius, Book i.

A student must obtain credit for four terms, or examinations, at least, in his two Freshmen years, in order to rise to the Junior Sophister Class. Of these four, one examination must be passed in the Junior Freshman year, and two terms, or examinations, in the Senior Freshman year, one of which must be the Michaelmas examination.

A student must obtain credit for three terms, or examinations, at least, in his Sophister years, before he can present himself for his degree examination. Of these three, one examination must be passed in the Junior Sophister year, and one term, or examination, in the Senior Sophister year.

### SCHOOL OF PHYSIC IN IRELAND.

This institution was established by several acts of parliament (21st Geo. II., 25th, 31st, and 40th Geo. III.), in consequence of bequests made by Sir Patrick Dun, a native of Aberdeen, in Scotland, and an eminent physician practising in Dublin. Its foundation and construction is peculiar, being composed of the three Professors appointed by act of parliament in Trinity College, to lecture on *anatomy and surgery, chemistry, and botany*; and of three other Professors, similarly appointed, to lecture on the *institutes of medicine, the practice of physic, and materia medica*; called the King's Professors in the city of Dublin, on the foundation of Sir Patrick Dun; elected by three Fellows of the College of Physicians and the Provost and Professor of Physic of Trinity College. No other person holds or can hold any other professorship in the SCHOOL of PHYSIC, unless, when the income derived from the estates of Sir Patrick Dun shall permit, a Professorship of Midwifery shall be established. The Provost and Senior Fellows of Trinity College are empowered to make rules and orders to regulate the conduct of the University Professors; and the College of Physicians are similarly empowered as regards the King's Professors, on the foundation of Sir Patrick Dun; with appeal to the Visitors of Trinity College on the one hand, and to those of the College of Physicians on the other; but no power exists enabling either of these bodies to disturb the constitution of this institution, or to add to or alter the professorships which compose it. Another body, however, the Electors of the King's Professors, are empowered to admonish any of these Professors who wilfully neglect their duties, and to deprive them of their professorships in case of obstinate neglect; as the Provost and Senior Fellows of Trinity College can admonish and deprive the University Professors. The act of parliament enjoins that the lectures of the University Professors shall be delivered in Trinity College, and that those of the King's Professors, on Sir Patrick's Dun's foundation, shall be delivered in the theatre erected for the purpose in Sir Patrick Dun's Hospital, and if not delivered there, the professorships are void. The University Professorship of Anatomy and Surgery also becomes void, as regards this institution, unless continued as such by Trinity College.

The SCHOOL of PHYSIC grants neither Degrees, Diplomas, nor Licences; but the certificates granted by it for attendance on its lectures and clinical hospital are received as qualification by the College of Physicians; and by Trinity College, if candidates presenting them are Graduates in Arts, but not otherwise. Students attending the Lectures of the University Professors, who are not Graduates or Undergraduates of Trinity College, are obliged to enrol themselves as such in the College books, for which they pay a fee of 5s., and this is nominated in the act of parliament a *matriculation*; but they are not required to pass any examination, or permitted to perform any academic exercises; the object being merely to bring them within the limits of College authority, in order to restrain them in case of misbehaviour.

The present King's Professors, on the foundation of Sir Patrick Dun, are—Dr. Law, on the institutes of medicine; Dr. Osborne, on *materia medica*; and Dr. Banks, on the practice of physic. The University Professors are—Dr. Harrison, on anatomy and surgery; Dr. Apjohn, on chemistry; and Dr. Allman, on botany. The fees for attendance are three guineas for each course, and pupils are required to enter their names on or before the 25th of November.

### ROYAL COLLEGE OF SURGEONS, ENGLAND.

*President*.—Cæsar H. Hawkins.

*Vice-Presidents*.—James Luke and Robert Keate.

*The Council*.—The President and Vice-Presidents, G. J. Guthrie, T. Copland, W. Lawrence, Sir B. C. Brodie, Bart., B. Travers, J. Swan, J. H. Green, E. Stanley, J. M. Arnott, J. F. South, F. C. Skey, B. B. Cooper, J. Hodgson, T. Wormald, G. Pilcher, J. Bishop, G. W. Mackmurdo, F. Kiernan, W. Coulson, G. Gulliver, and R. Partridge.

*Court of Examiners*.—The President and Vice-Presidents, G. J. Guthrie, W. Lawrence, B. Travers, E. Stanley, J. H. Green, J. M. Arnott, John F. South.

*Examiners for the Fellowship in Classics, Mathematics, and French*.—G. Smith, G. G. Stokes, and I. Brasseur.

*Professor of Anatomy and Physiology*.—F. C. Skey.

*Hunterian Professor and Conservator of Museum*.—R. Owen.

*Conservator*.—J. T. Quekett.

*Librarian*.—T. M. Stone.

*Secretary*.—E. Belfour.

*Regulations respecting the Education of Candidates for the Diploma of Member.*

Candidates will be required to produce the following certificates—viz, 1, of being twenty-one years of age; 2, of having been engaged during four years in the acquirement of professional knowledge; 3, of having studied practical pharmacy during six months; 4, of having attended at a recognized hospital or hospitals in the united kingdom the practice of physic during one winter and one summer session; 5, of having attended, during three winter and two summer sessions, the practice of surgery at a recognized hospital or hospitals in the united kingdom; 6, of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during three winter sessions; 7, of having attended, during two winter sessions, lectures on the principles and practice of surgery; 8, of having attended, during one summer session, lectures on *materia medica*, and lectures on midwifery; practical midwifery to be attended at any time after the conclusion of the session; 9, and of having attended one course of lectures on the practice of physic, and one course on chemistry.

Members or licentiates of any legally constituted college of surgeons in the united kingdom, and graduates in surgery of any university requiring residence to obtain degrees, will be admitted for examination on producing their diploma, licence, or degree, together with proof of being twenty-one years of age, and of having been occupied at least four years in the acquirement of professional knowledge.

Graduates in medicine of any legally constituted college or university requiring residence to obtain degrees, will be admitted for examination on adducing, together with their diploma or degree, proof of having completed the anatomical and surgical education required by the foregoing regulations, either at the school and hospital of the university where they shall have graduated, or at one or more of the recognized schools and hospitals in the united kingdom.

Candidates who shall have attended at recognized colonial hospitals and schools, the medical and surgical practice and the several courses of lectures, with the demonstrations and dissections, required by the foregoing regulations, will be admitted for examination upon producing certificates of such attendance, together with certificates of having attended in London, during one winter session, the surgical practice of a recognized hospital, and lectures on anatomy, physiology, and surgery, with demonstrations and dissections.

Certificates will not be recognized from any hospital unless the surgeons thereto be members of one of the legally constituted colleges of surgeons in the united kingdom; nor from any school of anatomy and physiology or midwifery, unless the teachers in such school be members of

some legally constituted college of physicians or surgeons in the united kingdom ; nor from any school of surgery, unless the teachers in such school be members of one of the legally constituted colleges of surgeons in the united kingdom.

Certificates will not be received on more than one branch of science from one and the same lecturer : but anatomy and physiology—demonstrations and dissections—will be respectively considered as one branch of science ; and in those schools in Scotland or Ireland in which such division of those subjects is sanctioned by the College of Surgeons in each kingdom, the institutes of medicine,—anatomy, demonstrations, and dissections,—may be separately certified.

Certificates will not be received from candidates who have studied in London, unless they shall have registered their tickets at the College, as required by the regulations, during the last ten days of January, March, and October in each year ; nor from candidates who have studied elsewhere, unless their names shall duly appear in the registers transmitted during such studies from their respective schools. By order of the Council,

E. BELFOUR, Secretary.

N.B. In the certificates of attendance on hospital practice and on lectures, it is required that the dates of commencement and termination be clearly expressed ; and no interlineation, erasure, or alteration will be allowed.

Blank forms of the required certificates may be obtained on application to the Secretary, to whom they must be delivered, properly filled up, ten days before the candidate can be admitted to examination ; and all such certificates are retained at the College.

#### ARMY MEDICAL SERVICE,

12, St. James's-place.

*Inspector-General of Hospitals and Superintendent of the Medical Department*—Dr Andrew Smith.

*Professional Assistant*—Dr. Thomas Spence.

*Inspector of Medicines, &c.*—Staff-Surgeon Pilleau.

*Apothecary to the Forces*—F. M. Bassano, Esq.

REGULATIONS—DATED FEBRUARY, 1840.

Candidates are required to produce the diploma of the College of Surgeons of London, Edinburgh, or Dublin, and the following testimonials :—

Eighteen months' attendance at an hospital of celebrity, where the average number of in-patients is not less than one hundred ; twelve months' anatomy ; twelve months' practical anatomy ; six months' physiology ; twelve months' surgery, or (what is preferred) six months' surgery, and six months' military surgery ; eight months' clinical surgery, a complete course of two or three lectures during the week ; twelve months' practice of physic, or six months' practice of physic, and six of general pathology ; eight months' clinical lectures on ditto, the same as required in surgery ; twelve months' chemistry ; six months' practical chemistry ; three months' botany ; three months' materia medica ; three months' practical pharmacy or apprenticeship ; three months' natural history ; three months' midwifery ; three months' practical midwifery ; one course natural philosophy ; one course logic.

The candidates must be unmarried, not beyond twenty-five years of age, nor under twenty-one years.

Candidates who have had an university education, and have the degree of A.B. or A.M., as well as that of M.D., will be preferred ; but a liberal education, and a competent knowledge of the Greek and Latin languages, are indispensably requisite in every candidate.

The greater the attainments of the candidates, the more eligible will they subsequently be deemed for promotion, as selections to fill vacancies will be guided more by reference to such requirements, especially in the higher ranks, than to mere seniority.

Although the British schools are specified, it is to be understood that candidates who have received regular education in approved foreign universities or schools will be admitted to examination.

With the exception of practice of physic and clinical medicine by one teacher, candidates must have attended separate lecturers for each branch of science.

Before promotion from the rank of assistant-surgeon to any higher rank, every gentleman must be prepared for such other examination as may be ordered before a board of medical officers.

Diplomas, tickets of attendance on lectures, and certificates of regular attendance by each professor or lecturer, must be lodged at this office for examination and registry at least one week before the candidate appears for examination ; likewise certificates of moral conduct and character, one of them by the parochial minister, if possible. Baptismal certificates are required at the same time, and if the parish register cannot be resorted to, an affidavit from one of the parents, or some near relative who can attest the fact, will be accepted.

The certificate of the teacher of practical anatomy must state the number of subjects or parts dissected by the pupil. Certificates of lectures and attendance must be from physicians or surgeons of the recognized colleges of the united kingdom, or of foreign universities.

All candidates for medical appointments are required to be conversant with "Cullen's Nosology."

#### ORDNANCE MEDICAL DEPARTMENT,

63, Pall-mall.

*Inspector-General*—Mr. James Stewart.

*Deputy Inspector-General*—Dr. Verling.

*Provisional List.*—Medical students who have completed their twentieth year, who have been well instructed in Latin and Greek, the elements of mathematics and natural philosophy, and who can produce satisfactory proofs of being diligent in the study of their profession, and the sciences connected with it, may be entered in the Provisional List of gentlemen desirous of being admitted candidates for the Ordnance Medical Department.

*Candidates.*—No applicant is to be received on the list of candidates before he is twenty-two, nor retained on it after he is twenty-five years of age. The age of every individual must be verified by a certificate of his baptism, if it can be procured ; but if not, by a solemn declaration of one of his parents, or of some other person who can attest the date of his birth.

*Qualifications.*—Every candidate must bring proof of having diligently served five years to a surgeon and apothecary, if educated in England ; but if not, qualification in the practice of medicine and pharmacy equivalent thereto. Of having attended the practice of surgery in a recognized hospital or hospitals, where clinical instruction is constantly given for three years, three months being allowed for a vacation in each year. Of having attended anatomical lectures, demonstrations, dissections, three anatomical seasons or sessions ; morbid anatomy and pathology, one course ; lectures on the principles and practice of surgery delivered in two distinct periods or sessions, two courses, each comprising seventy lectures, or one course of surgery and one of military surgery ; natural history or comparative anatomy, one course ; chemistry, one course of 100 lectures ; botany, one course ; materia medica and therapeutics, one course of 100 lectures ; lectures on the principles and practice of medicine, two courses, each 100 lectures, second third winters ; medical practice with clinical lectures, eighteen months, commencing the second session—viz., twelve months in a recognized hospital, and the remaining six months either in a recognized hospital or a dispensary ; medical jurisprudence with toxicology, one course of 50 lectures ; midwifery, two courses, each of 60 lectures, second and third sessions ; practical midwifery (not less than thirty cases) after the conclusion of the first course on midwifery lectures, a certificate of having passed the usual examination is to be produced ; diseases of the eye (with attendance on patients of that class), one course.

He must produce a diploma from either of the Colleges of London, Edinburgh, or Dublin, and, if not a graduated

M.D. of Scotland or Ireland, after having actually passed an examination in the university where he has obtained his degree; a certificate also of qualification from the Society of Apothecaries in London. It is likewise expected that candidates shall have attended establishments for the cure of diseases of the ear and skin, and for the treatment of patients affected with mental derangement.

### EAST INDIA MEDICAL SERVICE.

East India House, Leadenhall-street.

Surgeons—Dr. Jackson and Mr. Westall.

Examining Medical Officer—Dr. Scott.

#### Regulations.

**Age.**—The assistant-surgeon must not be under twenty-two years, in proof of which he must produce an extract from the register of the parish in which he was born, or his own declaration and other certificates agreeably to forms to be obtained in the East India House for cadets and assistant-surgeons.

**Qualification in Surgery.**—The assistant-surgeon, upon receiving a nomination, will be furnished with a letter to the court of examiners of the Royal College of Surgeons, to be examined in surgery; or should the assistant-surgeon be previously in possession of a diploma from the Royal College of Surgeons of London, or of the Colleges of Surgeons of Dublin or Edinburgh, or of the College and University of Glasgow, or of the Faculty of Physicians and Surgeons of Glasgow, either of them will be deemed satisfactory as to his knowledge of surgery, without any further examination. He is also required to produce a certificate from the cupper of a public hospital in London, of being capable of practising with proper dexterity the art of cupping.

**Qualification in Physic.**—The assistant-surgeon will also be required to pass an examination by the company's examining physician in the practice of physic, as much anatomy and physiology as is necessary, and the art of prescribing and compounding medicines; and he will be required to produce proof of his having attended at least two courses of lectures on the practice of physic; and a certificate of having attended diligently the practice of the physicians at some general hospital in London for six months; or at some general hospital in the country (within the united kingdom) for six months, provided such provincial hospital contain at least, on an average, one hundred in-patients, and have attached to it a regular establishment of physicians as well as surgeons. No attendance on the practice of a physician at any dispensary will be admitted.

### ROYAL COLLEGE OF SURGEONS IN IRELAND.

List of gentlemen who obtained the Diploma of the College during the present year:—

John M. O'Reilly, Dublin  
Charles F. Anderson, do.  
Robert T. Furlong, Wexford  
James Brown, Dublin  
Peter Reynolds, Tyrrells' Pass  
Thos. McCarthy, Rathmines  
Pierre T. Connolly, Waterford  
Henry S. Halahan, Dublin  
Charles Allen, Sligo  
William Butler, Rathmines  
William Carte, Dublin  
Abel W. Doyle, do.  
Digby Lawlor, Portarlington  
Alexander F. Bartley, Dublin  
Arthur T. Greer, do.  
Charles W. Perceval, do.  
Charles H. Hyde, Longford  
David Woods, Banbridge  
Henry C. Boate, Dungarvan  
Bindon Seymour, co. Galway  
Frederick Lloyd, Dublin  
Richard Stanistreet, Youghal  
Daniel Ryan, Limerick  
James Stewart, Dublin  
William T. Harding, do.

James T. T. Doyle, Dublin  
Howard B. Montgomery, do.  
William G. Hill, —  
Archbald Stevenson, Dromore  
Robert Speedy, Dublin  
John Johnson, Baltinglass  
G. Pilkington, Carrick House  
Walter Thorpe, Dublin  
John McCoy, Dundalk  
John Cullinan, Ennis  
Thomas McGahan, Bailieboro  
William Cookman, Wexford  
John B. Newell, Gowran, co. Kilkenny  
Robert P. White, Dublin  
J. McGettigan, Letterkenny  
William H. Cruice, Belmullet  
William T. Martin, Dublin  
Thomas T. Murphy, Waterford  
John K. Barton, Dublin  
William H. Tomlinson, Mill Park, co. Carlow  
William B. Wallis, Dublin

### THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY.)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System.

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

### SHIRTS CUT BY MACHINERY.

WEBB AND CO.'S

New System of Shirt-cutting by Machinery enables them to produce really First-class Shirts at prices lower than they have ever yet been offered.

Their Eglinton Shirts,

at 2s. 6d., 3s. 6d., and 4s. 6d. each,

are accurately Cut, elegant in Design, and perfectly sound in Fabric.

A large assortment of Fancy Veined Full-dress Shirts always on hand.

### THE TAILORING AND GENERAL OUTFITTING WAREROOMS

are now most extensively supplied with every description of WINTER CLOTHING.

### THE READY-MADE DEPARTMENT

contains an immense variety of

Top Coats, Travelling Coats, Wrapper Coats, Pilot and Frieze Pea Coats,

at 15s., 17s. 6d., and 20s. each,

which, for Workmanship and Solid Value, are not and cannot be surpassed.

WEBB AND CO.,

10, 11, and 12, CORN-MARKET.

### HOSPITAL SULPHATE OF QUININE, PURE CRYSTALLIZED,

Prepared by EDWARD HERRING, of the late firm of HERRING, Brothers, for the use of Hospitals, Dispensaries, &c.

THIS Sulphate of Quinine is chemically pure, its form of crystal is the same and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is unbleached and the other bleached. It was originally introduced for the use of Hospitals, Dispensaries, and public Charities, but its purity and great reduction in price is attracting the attention of Medical Men and the Dispensing Chemists.

It is put up in bottles (free) of three ounces and six ounces each, capsuled, with the name of the Proprietor, and labelled with the name of the Inventor. The peculiar mode of preparing the unbleached and white sulphates is being made the subject of a patent, and will shortly be made public.

Both articles to be had of the leading Druggists in London and the united kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.  
October 23, 1852.

## SCHOOL OF SURGERY.

## ROYAL COLLEGE OF SURGEONS IN IRELAND.

WINTER SESSION 1852-53.

THE Dissecting-rooms opened on the 1st of October, and the Lectures commenced on the 25th.

Anatomy and Physiology—Dr. Jacob.  
Descriptive Anatomy—Dr. Hart and Dr. Power.  
Surgery—Mr. Porter and Mr. Hargrave.  
Practice of Medicine—Dr. Benson.  
Chemistry—Dr. Barker.  
Midwifery—Dr. Beatty.  
Comparative Anatomy—Dr. Jacob.  
Dissections by the Professors of Anatomy and the Demonstrators—Dr. Leeson, Mr. T. D. Hargrave, Mr. Malcomson, and Mr. J. Morgan.

## SUMMER SESSION.

Materia Medica—Mr. Williams.  
Medical Jurisprudence—Dr. Geoghegan.  
Botany—Dr. A. Mitchell.  
Practical Chemistry—Dr. Barker.

The fee for each of the above Courses is two guineas, except Comparative Anatomy, which is free.

A public course of lectures on Comparative Anatomy and Zoology, free to all students, is delivered by the Professor of Anatomy and Physiology at the commencement of the session, and additional lectures on the same subject at intervals during the winter.

Practical instruction in Operative Surgery is given by the Professors of Surgery, separate from the surgical lectures. Fee, £5 5s.

The Professor of Chemistry receives operating pupils into the Chemical Laboratory.

The following Ordinance was made by the Council of the College on the 9th of April, 1851:—"To enable surgical students to devote more time to hospital attendance and dissection during the winter session, the lectures on materia medica, medical jurisprudence, practical chemistry, and botany, shall be delivered during the summer session in the school of the College, and in the schools recognized by the College; and certificates granted subsequent to the 30th of April, 1851, shall not be received as qualification for Letters Testimonial, unless issued in conformity with this regulation." Similar regulations have been adopted by the Council of the College of Surgeons of England.

## Hours of Lecture:

Descriptive Anatomy—Twelve o'clock every day.  
Chemistry—One o'clock, Mondays, Wednesdays, and Fridays.

Anatomy and Physiology—Two o'clock every day, except Monday.

Surgery—Three o'clock, Tuesdays, Thursdays, and Saturdays.

Practice of Medicine—Three o'clock, Mondays, Wednesdays, and Fridays.

Midwifery—Four o'clock, Tuesdays, Thursdays, and Saturdays.

Dissections from sunrise to sunset; one or more of the Demonstrators being always present to give instruction.

The Professor of Botany will commence a course of lectures on Structural and Physiological Botany in February. This course, taken in conjunction with that on Comparative Anatomy and Zoology, by the Professor of Anatomy and Physiology, constitutes the course of Natural History required by the Army Medical Board.

Pupils attending the Lectures on Midwifery and Diseases of Women and Children are admitted to the practice of a recognized midwifery hospital on payment of a fee of £4 4s.

The Professor of Medical Jurisprudence gives practical instruction in Toxicology in his Laboratory.

CITY OF DUBLIN HOSPITAL,  
Upper Baggot-street.

The Winter Session commenced on Monday, October 25.

The arrangements of this hospital are such as to afford the student an opportunity of studying disease in all its forms—Medical and Surgical. The morning visit commences daily at half-past eight o'clock, when the nature, treatment, and progress of each case are explained at the bedside of the patient, and ample opportunity afforded to every pupil of becoming practically acquainted with the uses of the Stethoscope. Clinical Lectures are delivered after the hospital visit.

Connected with the hospital is an extensive Dispensary, at which the pupils are allowed to perform the minor operations, under the guidance of the surgeons, and are rendered familiar with the details of dispensary management.

Every facility is given to students desirous of acting as Dressers and Clinical Assistants, subsequent to which all pupils of the hospital are eligible to the situation of House-Surgeon, according to merit.

A distinct course of Lectures upon Diseases of the Eye is delivered by Dr. Jacob, which the pupils are privileged to attend without additional fee, and special wards are appropriated for the reception of Eye Cases. Extended opportunities are thus afforded for acquiring a thoroughly practical knowledge of this important subject.

A ward is appropriated to the Diseases of Females, and clinical instruction is given upon all forms of Uterine Affection by Dr. Beatty.

Mr. Tufnell's course of Lectures upon Military Surgery is also open to the pupils of the hospital. This course is recognized as equivalent to six months' surgery in the professional qualification of candidates for admission into the Army, Navy, and Ordnance Medical Departments, and is required to be attended by all gentlemen entering the Hon. East India Company's Service.

A Lending Library of well-chosen books has been provided for the use of the pupils; and a correct Registry of the cases in hospital is kept by the House-Surgeon, to which they have free access.

Certificates of attendance on this hospital are recognized by all the Colleges, Universities, and Halls, and by the Army and Navy Medical Boards.

Fee for Winter six months	...	...	Six guineas.
" Summer six months	...	...	Four guineas.
" Nine months	...	...	Eight guineas.

## Medical Attendants.

- A. Jacob, M.D., Fellow and Professor of Anatomy and Physiology, Royal College of Surgeons, 28, Ely-place.  
T. E. Beatty, M.D., Fellow and Professor of Midwifery, Royal College of Surgeons, 18, Merrion-square, North.  
C. Benson, M.D., Fellow and Professor of the Practice of Medicine, Royal College of Surgeons, 34, York-street.  
W. Hargrave, M.D., Fellow and Professor of Surgery, Royal College of Surgeons, 37, York-street.  
R. C. Williams, M.D., Fellow and Professor of Materia Medica, Royal College of Surgeons, 14, Lower Fitzwilliam-street.  
T. G. Geoghegan, M.D., Fellow and Professor of Forensic Medicine, Royal College of Surgeons, 52, York-street.  
J. Tufnell, Esq., Fellow of the Royal College of Surgeons, 58, Lower Mount-street.

## Consulting Physicians.

Sir Henry Marsh, Bart., and Professor Apjohn.

## Consulting Surgeons.

Sir Philip Crampton, Bart., Professor Porter, and J. W. Cusack, M.D.

For further particulars apply to Dr. Benson, York-street.

## PRACTICE OF PHYSIC.

Dr. BENSON will commence the Course of Lectures on the Principles and Practice of Physic in the Royal College of Surgeons on Wednesday, the 10th day of November, at Three o'clock p.m.

The Description, Pathology, Diagnosis, and Treatment of Medical Diseases will form the subject of the Course.

Pathological Preparations, Plates, and recent Specimens of Diseased Parts, will be exhibited for the purpose of illustration. The Lectures will be delivered on Mondays, Wednesdays, and Fridays, throughout the session, at Three o'clock.

N.B.—Gentlemen entering the Army are required to attend Two Courses of Lectures on the Practice of Medicine; those entering the Navy to attend Three such Courses.

Fee for each Course ... .. Two guineas.

**DISEASES OF THE EYE**

**DR. JACOB** will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

THE  
**RICHMOND SURGICAL, WHITWORTH MEDICAL,  
AND  
HARDWICKE FEVER HOSPITALS,**  
*North Brunswick-street.*

The Course of Attendance and Clinical Lectures at the above mentioned hospitals will commence on Wednesday, the 3rd of November, 1852, at eleven o'clock a.m., when Dr. Corrigan will deliver the Introductory Lecture. The Course will be continued during the Winter and Summer Sessions.

These hospitals contain 300 beds, and have attached to them the Talbot General Dispensary, the Lunatic Asylum at Island Bridge, and the Truss Establishment for the Relief of the Ruptured Poor of Ireland; also a well-selected Medical and Surgical Library.

There is also an extensive Museum, containing nearly four thousand Morbid Preparations, Casts, and Drawings, available for clinical instruction, and always accessible to the hospital class.

The Surgeons visit daily at half-past eight o'clock, and the Physicians daily at ten o'clock a.m.

Two Surgical and two Medical Clinical Lectures will be delivered in each week.

The Resident Pupils and Clinical Clerks of the Richmond, Whitworth, and Hardwicke Hospitals are selected from the class, according to merit.

Two Prizes will be given at the end of the Winter Session—one in Clinical Surgery, and one in Clinical Medicine.

The Instruction in Clinical Medicine is given by—

**Dr. Corrigan, M.R.I.A.**, Physician in Ordinary to the Queen in Ireland, Lecturer on the Practice of Medicine in the Carmichael School of Medicine, &c.;

**Dr. Banks, M.R.I.A.**, Honorary Fellow of the King and Queen's College of Physicians in Ireland, King's Professor of the Practice of Medicine, Physician Extraordinary to the Richmond Lunatic Asylum;

**Dr. McDowell, F.R.C.S.I.**, Lecturer on Anatomy and Physiology in the Carmichael School of Medicine, &c.;

**Dr. Gordon, F.R.C.S.I., M.R.I.A.**, Physician to the Government Lunatic Asylum at Island Bridge.

The Instruction in Clinical Surgery is given by—

**Dr. Hutton, M.R.I.A.**, President of the Royal College of Surgeons in Ireland, Surgeon to Simpson's Hospital, &c.;

**Dr. Adams, F.R.C.S.I., M.R.I.A.**, &c.;

**Mr. Hamilton, F.R.C.S.I., M.R.I.A.**, Examiner in Surgery to the Queen's University, Lecturer on Surgery in the Carmichael School of Medicine, &c.;

**Dr. R. W. Smith, F.R.C.S.I., M.R.I.A.**, Professor of Surgery in the University of Dublin;

**Dr. Christopher Fleming, F.R.C.S.I., M.R.I.A.**, Surgeon to the Netterville Institution, &c.

In the immediate vicinity of these Hospitals is the Carmichael, late the Richmond Hospital, School of Medicine, where regular Courses of Lectures are delivered on the several subjects of medical science.

Attendance for nine months on the practice of a general hospital, with attendance on the clinical lectures on medicine and surgery therein delivered, is, by a recent regulation of the Board of Trinity College, required from candidates for the degree of M.B.

The London College of Surgeons require a list of the pupils entering for the Winter Session to be transmitted to their Secretary, on or before the 25th of November next.

*Terms of Attendance.*

For the Winter Session of six months, Eight guineas.  
For the Summer Session of three months, Three guineas.

For further particulars apply to the Secretary, Dr. Hutton, 29, Gardiner's-place, or at the Hospitals.

**JERVIS-STREET HOSPITAL, DUBLIN.**

The Winter Session 1852-53 begins on the 1st November.

The Hospital, which contains Eighty beds, will be visited daily at nine o'clock a.m.; and arrangements have been made to prevent the hours of attendance and lectures from interfering with any other place of instruction in Dublin. An extensive Dispensary is attached, in which the pupils are allowed to perform all the minor operations in surgery, under the guidance of the attending surgeons; and two wards have been recently fitted up for the treatment of Diseases of the Eye.

Two Medical and two Surgical Clinical Lectures will be delivered weekly by the attending Physicians and Surgeons, and due notice of Operations will be given, unless in cases of emergency.

The situation of Resident Pupil is open to pupils as well as apprentices of the Hospital, and the appointment for the ensuing session will take place on Monday, November 8th.

Certificates of attendance at this Hospital are recognized by the King and Queen's College of Physicians, the Queen's University, the University of Edinburgh, the Army Medical, Navy, and East India Boards, and all the licensing bodies in the kingdom.

In addition to the ordinary Clinical Instruction, a special Course of Lectures will be delivered during the ensuing session, for which distinct certificates will be given.

*Physicians.*

**J. Moore Neligan, M.D., M.R.I.A.**, Lecturer on the Practice of Medicine in the Dublin School of Medicine.

**John Hughes, L.K. and Q.C.P., and R.C.S.I.**, one of the Medical Officers of the Richmond Lunatic Asylum.

*Surgeons.*

**R. P. O'Reilly, F.R.C.S.I.**

**Andrew Ellis, F.R.C.S.I.**, Professor of Surgery to the Apothecaries' Hall, Dublin.

**M. H. Stapleton, M.D., M.R.I.A., F.R.C.S.I.**, Professor of Anatomy to the Royal Hibernian Academy.

**R. Harrison, M.D., M.R.I.A., F.R.C.S.I. and E.**, Professor of Anatomy and Physiology, Trinity College, Dublin.

**A. Banon, M.D., F.R.C.S.I.**, Medical Attendant of the Richmond Government Prison, and Acting Physician to the City of Dublin Prisons.

**James S. Hughes, M.D., F.R.C.S.I.**

**J. H. Power, M.D., F.R.C.S.I.**, Professor of Anatomy in the Royal College of Surgeons in Ireland.

*Fees for Hospital Attendance and Lectures.*

Winter Session	...	...	Six guineas.
Nine Months	...	...	Eight guineas.
Perpetual Pupils	...	...	Twenty guineas.

For further particulars apply to Mr. Macgrath, at the Hospital, or to any of the Physicians or Surgeons.

**LYING-IN HOSPITAL,**

*Rutland-square, Dublin.*

This Hospital, established by Royal Charter of Geo. II., 1756, contains 140 beds, fifteen of which are appropriated to the Diseases of Females. Upwards of two thousand women are annually delivered in this institution by the pupils, under the superintendence of the resident medical officers.

There is a Museum and library for the use of the students, and comfortable accommodation for intern pupils.

This hospital is recognized as a school for the delivery of Lectures on Midwifery, by the Master, by the Royal Colleges of Surgeons in England and Ireland; by the King and Queen's College of Physicians, Dublin; the Apothecaries' Hall of Dublin, and all other licensing bodies.

The Winter Course of Lectures begins in November; the Summer, in May.

Application to be made to the Master, Dr. Shekleton, at the Hospital.

**THE REVERSED AND DOUBLE-ACTIONED  
PATENT TRUSS.**

Invented by FRANCIS L'ESTRANGE, Esq., F.R.C.S.I.

**WILLIAM DUFF**, of 37, Molesworth-street, Dublin, calls the attention of the Medical Profession and the Public to this Truss. He can state with confidence it is the only instrument constructed on Scientific Principles, having for its object the Radical Cure of Rupture. It acts not merely as a palliative, but will produce a radical cure, as is attested by numerous certificates.

W. D. is the only Manufacturer of the Instrument. The trade and public institutions will be liberally dealt with.

## MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY.

The Winter Session commenced on the 1st of October. The usual courses of Clinical Instruction will commence on the first Monday in November, and will be continued through the session by the Physicians and Surgeons of the Institution.

Arrangements have been made to prevent the hours of attendance and lectures from interfering with any other place of instruction in Dublin.

The Medical and Surgical Clinical Instruction will be carried on on the alternate days—Mondays, Wednesdays, and Fridays for SURGICAL; and Tuesdays, Thursdays, and Saturdays for MEDICAL Instruction.

Operations, unless in cases of emergency, will only be performed on the days of surgical instruction.

A Surgical Registry of all cases admitted into the hospital is carefully preserved, and is open to the inspection of the pupils. A dispensary is attached to the hospital, in which the pupils are allowed to perform all the minor operations in surgery, under the guidance of the attending surgeons. From 200 to 300 patients are prescribed for and relieved in the dispensary daily.

The following premiums are to be awarded, as usual, at the close of the session:—

1. The Clinical Medical Premiums.
2. The Clinical Surgical Premiums.

Of these there are two in each class to be awarded according to the order of merit.

The situation of Resident Pupil is open to pupils as well as apprentices of the hospital.

Special recommendatory certificates are given to such gentlemen as have filled the situation of Clinical Practising Assistants in the hospital for at least four months to the satisfaction of the medical officers.

Certificates of attendance on this hospital are acknowledged by all the Colleges, Halls, and Boards.

The Medical Clinical Instruction is given by Dr. Stokes, Regius Professor of the Theory and Practice of Physic, Trinity College, Dublin, &c.; and Dr. Lees, Fellow of the College of Physicians, Lecturer on the Practice of Physic, Examiner in Medicine to the Queen's University in Ireland, &c.

The Surgical, by Sir Philip Crampton; Mr. Porter, A.M., Professor of Surgery, Royal College of Surgeons, Ireland, &c.; Mr. Smyly, A.M., F.R.C.S.I., &c.; Mr. G. Porter, A.M., F.R.C.S.I., &c.; Mr. Collis, A.M., F.R.C.S.I., &c.; and Mr. Rynd, A.M., F.R.C.S.I., &c. &c.

For further particulars apply to Francis Rynd, Secretary, No. 49, Ely-place, or at the hospital.

## DOCTOR STEEVENS' HOSPITAL.

The Winter Course of Attendance at this Hospital will commence on Monday, the 1st of November, at eight o'clock a.m.

Clinical Lectures will be delivered on Mondays, Wednesdays, Thursdays, and Fridays, at half-past eight o'clock a.m.

Medical Clinical Lectures by Sir H. Marsh, Bart., Physician in Ordinary to the Queen in Ireland, &c. &c.; Dr. C. P. Croker, Physician to Swift's Hospital for the Insane, &c. &c. &c.

Surgical Clinical Lectures by Mr. Cusack, University Professor of Surgery, Surgeon to Swift's Hospital for the Insane; Mr. Colles, F.R.C.S.I.; and Mr. Wilmot, F.R.C.S.I., Lecturer on Surgery in the Carmichael School of Medicine, &c. &c.

This Hospital contains 230 patients, and is provided with distinct wards for Venereal Complaints and Diseases of Children. A large Dispensary is attached to the institution, also an extensive Medical and Surgical Library.

There are, in addition, furnished apartments for eight Resident Pupils, two Surgical Clinical Clerks, and one Medical.

Four prizes will be given at the end of the session—two in Clinical Surgery, and two in Clinical Medicine.

As the Hospital is visited early in the morning, and with strict punctuality, no difficulty is experienced by the pupil in attending lectures at the various schools of medicine in the city.

N.B.—The Hospital adjoins Swift's Lunatic Asylum.

Terms of attendance on the Medical and Surgical Wards, Lectures included:—

Winter Session of six months	Eight guineas.
Summer Session of three months	Three guineas.
Intern Dressership for Winter six months,	Twenty guineas.
Ditto, Summer six months,	Fifteen guineas.

For further particulars apply to the Resident Surgeon at the Hospital.

## SAINT VINCENT'S HOSPITAL, 38

*Stephen's-green.*

The Winter Session for the Attendance of Pupils on the Practice of this Hospital will commence on Monday, 1st of November, 1852.

The Hospital, which is on the principle of the hospitals in Paris, contains one hundred beds, constantly occupied by instructive cases.

A large Ward has been opened for the reception of children, on the plan of the "*Enfants Malades*," and will afford opportunities for studying the diseases of early life.

Connected with the Hospital is an extensive Dispensary, where abundant means are presented for the acquisition of Medical and Surgical knowledge.

The Hospital will be visited daily at eight o'clock a.m. Clinical Lectures will be delivered twice every week during the Session, and Clinical Instruction daily.

The Clinical Lectures will be illustrated by a splendid collection of Original Drawings, Casts, and Preparations.

Certificates of attendance on the practice of this Hospital are recognized by the Colleges of Surgeons in London and Dublin, the London University, the Queen's University in Ireland, the Apothecaries' Hall, Dublin and London, the Army and Navy Medical Boards, &c. &c.

In order to encourage that branch of study, Dr. O'Ferrall will, at the end of the Session, award a Prize to the pupil who shall produce the series of cases containing the most accurate description of Diseases in Children.

### Medical Advisers.

First: J. M. O'Ferrall, Esq., M.D., M.R.I.A., F.R.C.S.

Second: O'B. Bellingham, Esq., M.D., F.R.C.S.

### Consultants.

Sir Philip Crampton, Bart., M.D., F.R.S., F.R.C.S.

Sir Henry Marsh, Bart., M.D., M.R.I.A.

Further particulars may be learned by inquiring at the Hospital during the hours of attendance.

## CARMICHAEL SCHOOL OF MEDICINE.

WINTER SESSION OF 1852-53.

The Winter Course of Lectures will commence on Monday, 1st day of November, at Twelve o'clock, and continue six months.

Anatomy and Physiology—Dr. Mayne and Dr. McDowel.

Surgery—Dr. Hamilton and Mr. Wilmot.

Medical Jurisprudence—Dr. O'Reilly.

Practice of Medicine—Dr. Corrigan.

Midwifery—Dr. Denham.

Chemistry—Dr. Davy.

Materia Medica—Mr. Macnamara.

Botany—Dr. Frazer.

Demonstrations—Mr. Macconchy and Dr. Cryan.

Dr. Cryan and Mr. Macconchy will attend constantly in the rooms to assist students in Practical Anatomy, which has already commenced.

### CARMICHAEL PREMIUMS.

By a bequest of the late Mr. Carmichael, these premiums have been continued to the school. Public examinations will therefore be held, and premiums awarded, at the termination of the course, to the best answerers in the various branches taught in the school.

For further particulars apply to Dr. Mayne, 13, Upper Gloucester-street; Mr. Hamilton, 37, Westland-row; Dr. McDowel, 10, Great Denmark-street; Mr. Wilmot, Stephen's-green, west; or Dr. Macconchy, 1, Blessington-street.

## MILITARY SURGERY.

MR. TURNELL will commence the Course of Lectures on Military Surgery in the Theatre of the City of Dublin Hospital on Tuesday, November 16th, at Four o'clock p.m.

This Course is recognized as equivalent to Six Months' Surgery in the professional qualifications of Candidates for the Medical Departments of the Army, Navy, and Ordnance; and by an Order of the India Board, dated March 1, 1852, is rendered imperative upon all Gentlemen educated in Ireland, who may hereafter seek admission into the Hon. East India Company's Service.

# SCHOOL OF PHYSIC IN IRELAND.

(Established by act of parliament 40 Geo. III., and under the joint government of the Board of Trinity College and the King and Queen's College of Physicians.)

The Professors will commence their Annual Courses of Lectures, and Hospital Attendance on Monday, the 1st of November.

At 10 o'clock, Dr. Law, on the Institutes of Medicine and Pathology, every Wednesday, Thursday, Friday, and Saturday.

11 „ Dr. Osborne, on *Materia Medica* and Pharmacy, every Wednesday, Thursday, Friday, and Saturday.

1 „ Dr. Harrison, on Anatomy and Physiology.

2 „ Dr. Apjohn, on Chemistry.

2 „ Dr. R. W. Smith, on Surgery, on Fridays and Saturdays, and at eleven o'clock on Mondays.

3 „ Dr. Banks, on the Practice of Medicine, every Monday, Tuesday, Wednesday, and Thursday.

4 „ Dr. Montgomery, on Midwifery and the Diseases of Women and Children, every Monday, Tuesday, Wednesday, and Thursday.

The following Course delivered during the Summer Session:—  
Dr. Allman, on Botany,  
Dr. Apjohn, on Practical Chemistry,  
Dr. Brady, on Medical Jurisprudence.

Sir Patrick's Dun's Hospital will be visited at twelve o'clock daily, and Clinical Lectures delivered twice in each week during the Winter Session, as also during the months of May, June, and July.

The Course of Practical Anatomy and of Anatomical Demonstrations will be conducted by the Professor of Anatomy, assisted by the Demonstrators, Messrs. A. Brabazon and W. Peebles.

The fee for each of the above courses of lectures is three guineas; second course, two guineas; but Students in Arts of Trinity College, who have matriculated in medicine, will be permitted to attend one course, *free of expense*, with each of the University Professors.

The Library of the College of Physicians at Sir P. Dun's Hospital is open on every Tuesday and Friday for the delivery of books to students subscribing 1*l*s. annually.

Students may matriculate in medicine on payment of 5*s*. to the Senior Lecturer of Trinity College, and such have the privilege of attending the lectures on Natural Philosophy in the University, and have free access to the Museum of Natural History, and to the College Botanical Gardens, when Demonstrations in Botany will be delivered by the Professor of Botany.

All the lectures, with the exception of the clinical lectures, will be delivered in the Medical Lecture-rooms of the University. WM. E. STEELE, M.B.

Fellow and Registrar of the King and Queen's College of Physicians in Ireland.

## CORK SCHOOL OF MEDICINE.

The Twenty-sixth Winter Session commenced on the 22nd instant, at Two o'clock p.m.

Anatomy and Physiology—H. A. Cæsar, M.D.

Surgery—W. K. Tanner, M.D.

*Materia Medica*—J. F. McEvers, M.D.

Botany—T. Power, M.D.

Midwifery—W. C. Townsend, M.D.

Practice of Medicine—C. Y. Haines, M.D.

Chemistry—W. C. Nash, M.D.

Natural History—T. C. Shinkwin, M.R.C.S.

Natural Philosophy—Ed. McCarthy, Esq.

Practical Anatomy—H. A. Cæsar, M.D., T. C. Shinkwin, M.R.C.S., and E. Lundy, M.R.C.S. Eng.

This School, situate on the South Mall, midway between the North and South Infirmaries, has all the requisites for complete Medical Education. Its reputation, for over a quarter of a century, is best tested by the high character of its numerous "Alumni," not only in this city and province, but in each department of Her Majesty's service, and every quarter of the globe.

DISSECTIONS HAVE COMMENCED.

For particulars apply to Dr. Cæsar, South Mall. October 12, 1852.

# SCHOOL OF ANATOMY, SURGERY, AND MEDICINE,

*Cecilia-street, Dame-street.*

The Winter Session will commence on 2nd of November, at One o'clock.

Anatomy and Physiology—Dr. J. H. Corbett.

Surgery—Mr. Ellis.

Practice of Medicine—Dr. Aickin.

Chemistry—Dr. Aldridge.

Descriptive and Surgical Anatomy—Dr. Corbett, Dr. Murney, Dr. Byrne.

Practical Anatomy—Dr. Corbett, Dr. Murney, Dr. Byrne, Dr. Torney, W. H. Tomlinson, L.R.C.S.I.

The Dissections are conducted under the constant direction of the Professor and Demonstrators of Anatomy.

The several courses delivered in this School are recognized by all the Colleges of Physicians and Surgeons, the Army, Navy, and East India Boards, &c. &c.

The Summer Session will commence in May.

## MEDICAL SCHOOL.

### ANDERSON'S UNIVERSITY, GLASGOW.

The Winter Session will begin on Tuesday, November 2, 1852. Lectures will be delivered daily for Six Months on the following branches of Medical Science:—

Anatomy, Descriptive and Physiological—Dr. M. S. Buchanan.

Anatomy, Demonstrative and Surgical—Dr. M. S. Buchanan.

Demonstrator—Dr. George Buchanan.

Principles and Practice of Surgery—Dr. Hunter.

Principles and Practice of Medicine—Dr. A. Anderson.

Institutes of Medicine—Dr. E. Watson.

*Materia Medica*, Pharmacy, and Dietetics—Dr. Easton.

Chemistry—Dr. Penny.

Practical Chemistry—Dr. Penny.

Midwifery and Diseases of Women and Children—Dr. Paterson.

Medical Jurisprudence and Police—Dr. Crawford.

Natural Philosophy (thrice a week)—Dr. Taylor.

Mathematics—Mr. Laing.

Summer Courses of Anatomy, Midwifery, Chemistry, and Botany, begin in May.

Botany—Dr. Bell.

Fee for each class, £2 2*s*. Perpetual, £3 3*s*.

Certificates of attendance on the above courses are received by the Universities of Oxford, Cambridge, London, Aberdeen, and St. Andrew's; by all the Royal Colleges of Surgeons in Great Britain and Ireland; by the Faculty of Physicians and Surgeons in Glasgow; and by the Army, Navy, and East India Boards, and the Apothecaries' Company.

Students attending the Medical Classes have the opportunity of witnessing the practice of the following hospitals—viz., Lying-in Hospital, 10*s*. 6*d*. for six months; Eye Infirmary, £2 2*s*. for six months; Royal Infirmary, £8 8*s*. perpetual, including Medical and Surgical Clinical Lectures, which are delivered four times weekly. The patients admitted to the Eye Infirmary average 900 annually; those admitted to the Royal Infirmary, nearly 3,000, besides 6000 out-patients treated at the Dispensary; average number of Surgical Operations, 120 annually.

The Saloon for Dissection, which is free to those attending either of the above Courses of Anatomy, is open from nine a.m. to four p.m.; and attached to it there have been opened a Reading Room and Museum for the use of the Anatomical Students.

The new and extensive Laboratory of the Institution, fitted up expressly for gentlemen desirous of pursuing Practical and Analytical Chemistry, is open daily from eleven till four o'clock. No charge for Apparatus and Materials in the Class for Practical Medical Chemistry.

The University Museum, a splendid collection of Specimens of Natural History, including more particularly those of Zoology, Geology, Mineralogy, and Antiquities, is open to all Students attending the University. A valuable Medical Library is also attached to the Medical School.

### M. BOISSONNEAU'S MOVEABLE ARTIFICIAL EYES.

The periodicals of the day have of late been frequently mentioning the improvements of this art, which may be looked upon as almost new.

M. Boissonneau, Oculist, of London, has succeeded in giving to the Artificial Eyes all the movements of natural eyes; this astonishing property would almost seem incredible, if the fact had not been clearly mentioned in several numbers of the *Lancet*. The loss of an eye is no longer an irreparable misfortune, for M. Boissonneau has succeeded in removing the physiognomical defect, which is the consequence of such loss, by these newly-devised Artificial Eyes, which patients can apply themselves with the greatest ease. The movements of the artificial substitutes are so admirable, that it is hardly possible to distinguish Nature from Art. The use of these Eyes is fully appreciated by those who are aware how much irregularities of the face mar a man's career. Those persons who have had the misfortune of losing an eye, and who are wishing to remove, by means of a Moveable Artificial Eye, made of enamel, the physiognomical defect, which is the consequence of the loss they have experienced, are informed that M. Boissonneau will be in Dublin on the 29th, 30th, and 31st, instant, in order to supply patients with Artificial Eyes.

M. Boissonneau will be found at 19, Molesworth-street. Such indigent persons who have lost an eye, and who shall be recommended by members of the medical profession, clergymen, or guardians of the poor, will be supplied gratuitously with Artificial Eyes.

M. Boissonneau, notwithstanding his numerous journeys, will be regularly found at his residence in London, No. 14, Princes-street, Cavendish-square, from the 3rd to the 10th of every month.

### KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

At the Annual Stated Meeting of the College, held on St. Luke's day, the following Fellows were elected Office-bearers for the ensuing year:—

President—Dr. William Fetherston Montgomery.

Vice-President—Dr. Aquilla Smith.

Censors—Doctors Thomas Brady, William Stokes, Aquilla Smith, James Foulis Duncan.

Treasurer—Dr. John Mollan.

Librarian—Dr. George Alexander Kennedy.

Registrar—Dr. William Edward Steele.

Professor of Midwifery—Dr. W. F. Montgomery.

Professor of Medical Jurisprudence—Dr. Thomas Brady.

Midwifery Court of Examiners—Doctors Wm. O'Brien Adams, Henry Law Dwyer, Fleetwood Churchill.

Inspectors of Apothecaries' Shops—Doctors Thomas Brady, Aquilla Smith, James Foulis Duncan, William Edward Steele.

By order, W. E. STEELE, Registrar.  
October 18, 1852.

**G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.**

*Superior Dissecting Instruments well worth the inspection of the Student.*

### THE COMPOUNDING DEPARTMENT AT G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.  
G. O. and Co. continue to be Supplied with the FINEST MINERAL WATERS FRESH from their various SPRINGS.

 Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

### BOOKS FOR STUDENTS.

I.—HARRISON'S DUBLIN DISSECTOR; or System of Practical Anatomy. Fifth Edition, enlarged and improved. Two Vols. fcap., cloth, with 160 Illustrations.

II.—SMITH'S TREATISE on FRACTURES and DISLOCATIONS. One Vol., cloth, with 200 Engravings on Wood.

III.—CHURCHILL on the DISEASES of CHILDREN. One Vol. fcap., cloth.

IV.—KANE'S ELEMENTS of CHEMISTRY, Practical and Theoretical. Second Edition, revised and enlarged, with 230 Engravings on Wood.

V.—HARRISON'S SURGICAL ANATOMY of the ARTERIES of the HUMAN BODY. Fourth Edition. One Vol. fcap., cloth.

VI.—RICORD on BLENNORRAGIA and SYPHILIS. Edited by Dr. M. H. STAPLETON. 8vo, sewed, price 2s.

VII.—McCLINTOCK and HARDY'S PRACTICAL OBSERVATIONS on MIDWIFERY. One Vol. 8vo.

Dublin: Hodges and Smith, Grafton-street. London: Simpkin, Marshall, and Co., Stationers' Hall Court.

### DR. BELLINGHAM ON ANEURISM.

Lately published, 12mo, price 4s.,

### OBSERVATIONS ON ANEURISM AND ITS TREATMENT BY COMPRESSION.

By O'B. BELLINGHAM, F.R.C.S.I.,

One of the Surgeons of St. Vincent's Hospital.

"In our opinion, he has conferred a signal benefit upon the art of surgery by his improvement of the mode of employing pressure, and upon the science by his ingenious and philosophic exposition of its operation."—*Medico-Chirurgical Review*.

"Dr. Bellingham has ably advocated the cause of compression as a highly useful and successful mode of treating numerous cases of external aneurism."—*Lancet*.

"Dr. Bellingham's little work is well worthy of attentive perusal, and we feel a confident hope that henceforth another formidable operation (as ligature of the femoral vessel even under favourable circumstances unquestionably is) may in a great majority of instances be avoided."—*American Journal of the Medical Sciences*.

"The very excellent and practical essay lately published by Dr. Bellingham, to which we would refer our readers, as containing a most masterly account of the treatment of aneurism by compression."—*British and Foreign Medical Review*.

"I conceive that for a just exposition of the principles on which that mode of treatment should be conducted, as well as for some valuable improvements in the mode of procedure itself, the surgical profession is mainly indebted to you."—*Sir Philip Crampton's Letter to the Author*.

London: John Churchill, Princes-street, Soho.

Dublin: Fannin and Co., Grafton-street.

Price Five Shillings,

TRANSACTIONS of the CENTRAL RELIEF COMMITTEE of the SOCIETY of FRIENDS during the Famine in Ireland in 1846 and 1847, with a Copious Appendix, 512 pp.

Dublin: Hodges and Smith, Grafton-street. London: W. and F. S. Cash, 5, Bishopsgate-street Without.

Price One Shilling,

The TRANSACTIONS, 140 pp., without the Appendix, may be had in Wrapper.

8vo, price 7s. 6d., cloth,

**PATHOLOGICAL AND PRACTICAL OBSERVATIONS ON STRICTURES, AND SOME OTHER DISEASES OF THE URINARY ORGANS.**

By FRANCIS RYND, A.M.,

Fellow of the Royal College of Surgeons in Ireland; Surgeon to the Meath Hospital and County of Dublin Infirmary; Consulting-Surgeon to the Coombe Lying-in Hospital; Her Majesty's Medical Superintendent of Convicts in Ireland; Member of the Royal Medical Society of Edinburgh, of the Pathological Society, &c. &c.

"In this treatise, the causes, nature, and symptoms of stricture are explained; and its consequences, including disease of the bladder, retention of urine, and abscesses in the perineum, described. The treatment, both local and constitutional, is laid down; and the management of the catheter and bougie fully detailed. Disease of the prostate gland is also investigated, and its treatment considered. It contains in brief space, and at a moderate price, much valuable and instructive matter touching a subject which no surgeon can overlook. To us it appears a useful addition to our stock of information on this subject, and creditable to Irish surgery."—*Medical Press*.

"No volume was ever more correctly named according to its contents than that which is now before us; the diseases of which it treats are described from Nature, the views which it propounds are based on pathological science, and the treatment recommended is derived from an extensive practical acquaintance with the almost endless forms under which diseases of the urinary organs present themselves to the surgeon. We know of no work that presents such comprehensive or such admirable rules on the subject of treatment."—*London Medical Gazette*.

"The book is very carefully written, and may be consulted with advantage by those who are desirous of refreshing their knowledge, as also by the student."—*London Journal of Medicine*.

"The subject of fistula in perineo and its complications are treated of in this book in a remarkably clear and judicious manner. The remarks, &c., may be read with profit by all reflecting surgeons. It is, without doubt, an able and thoughtful production, and has our cordial recommendation as one of the best of the modern contributions to this branch of surgery."—*British and Foreign Medico-Chirurgical Review*.

"There is much that is good, both as regards the matter contained, and the manner in which the work is written. The remarks upon forcibly penetrating an impermeable stricture in retention, are excellent. There is much sound and valuable matter in this book."—*Lancet*.

"The practical precepts with which it is replete will amply remunerate the reader for the time expended in its study. We again repeat it as our deliberate opinion, that these 'Pathological and Practical Observations on Stricture' reflect great credit upon the author."—*Dublin Quarterly Journal of Medical Science*.

"We have been much pleased with the perusal of this work: it is full of sound practical research, and contains much that will prove valuable to the surgeon."—*The Medical Times*.

"It is eminently practical, which is the highest praise that, in my opinion, can be given to a surgical essay."—*Sir Philip Crampton's Letter to the Author*.

"Your book is an important addition to the series of Meath Hospital Works."—*Dr. Stokes's Letter to the Author*.

Longman, Brown, Green, and Longmans.

Just published, 8vo, pp. 96, price 2s. 6d.,

**A TREATISE ON CATARACT;**

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F.R.C.S.,

Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5s.,

**THE INFLAMMATIONS OF THE EYEBALL:**

Being a Treatise on all the Species and Varieties of Iritis.

Dublin: Fannin and Co., 41, Grafton-street, or the Office of the MEDICAL PRESS, 15, Molesworth-street. London: John Churchill, Princes-street, Soho.

**TEXT-BOOKS.**

First Course of Dr. LARDNER's Handbook of Natural Philosophy and Astronomy. Mechanics, Hydrostatics, Pneumatics, Sound, and Optics. Large 12mo, 400 Woodcuts, cloth, 12s. 6d.

"Our examination of the work leads us to speak most favourably of it as a handbook for students."—*Medical Gazette*.

Second Course of Dr. LARDNER's Handbook of Natural Philosophy and Astronomy. Heat, Common Electricity, Magnetism, and Voltaic Electricity. 200 Woodcuts. Large 12mo, cloth, 8s. 6d.

"\* The third course, completing the work, will contain Astronomy and Meteorology."

ELLIS's Demonstrations of Anatomy. Third Edition, small 8vo, cloth, 12s. 6d.

Dr. MURPHY's Lectures on the Principles and Practice of Midwifery. Complete in One Vol. 8vo, many Illustrations, 16s.

Dr. BALLARD on the Physical Diagnosis of Diseases of the Abdomen. 12mo, cloth, 7s. 6d.

KIRKES' and PAGET's Handbook of Physiology. Second Edition. 12mo. Illustrations on Steel and Wood, 12s. 6d.

## PROCEEDINGS OF SOCIETIES.

### MEDICAL SOCIETY OF LONDON.

#### NEW ACUPUNCTURE NEEDLE.

DR. LANKESTER exhibited an acupuncture machine, consisting of a number of needle points, which could be simultaneously inserted by a spring into the skin. He had seen it employed on the Continent, from whence he had brought it, as a means of counter-irritation; croton-oil, &c., being rubbed upon the part after the insertion of the needle-points.

#### ENORMOUSLY ENLARGED SPLEEN.

MR. W. B. RICHARDSON brought before the Society an enlarged spleen, which he had removed from the body of a woman, aged 55. The patient during her life was under the care of Dr. F. Smith of Richmond, who had kindly given Mr. Richardson the inspection. She was the mother of several children, and had been ill for some months past. The existence of a large substance in the abdomen was known. For some time previous to death, the action of the kidneys had been sluggish, and ascites had appeared once or twice. She had also become much emaciated, and died from mere asthenia.

*Autopsy.*—The thorax, viewed externally, was seen to be small; the abdomen was large, and the rest of the body was shrunken; there was little rigidity. Internally the spleen was found to be universally enlarged, weighing three pounds and a half, and having a speckled appearance from fibrinous spots; it encroached very much on the left side of the abdomen, covering and exerting great pressure on the left kidney. The left kidney was diminished in size; the right one was normal both in size and appearance. Other abdominal organs were natural. The left pleural cavity contained nearly three pints of fluid, by which the left lung was compressed to less than half its normal dimensions; the right lung was large and inflated with air. The heart was exceedingly small (not larger than the heart of a child five or six years old), and was pale in appearance, but it contained no fluid blood or clots, and its valves were healthy.

Mr. Richardson made one or two practical remarks on the case. The mode in which the large spleen had proved an indirect cause of death was interesting in a mechanical point of view. The pressure of the spleen on the kidney, and on the abdominal veins, had probably prevented the due evacuation of fluid matter from the body. Upon this had supervened the dropsy of the thorax, at which point the train of effects commenced which led directly to the fatal result. The pressure of the fluid in the thorax told upon the heart, impeding its action and causing atrophy of its walls. The central circulating organ was thus rendered incompetent for the office of propelling the nutrient blood round the body. The digestive process then became impaired, while such impairment would in its turn react upon the heart, thus hurrying on that asthenic state which ended in death. A second point of interest in the case was the fact, that although one kidney was atrophied, the other had undergone no compensating enlargement. This, Mr. Richardson thought, was owing to the age of the patient, and he expressed an opinion that the process of compensation by one organ, for the faults of a fellow organ, was limited by age, such compensation rarely occurring after the middle period of life. Lastly, this was a case which showed the necessity of taking general views of disease. A valued Fellow of the Society had once said, that at one of our special hospitals, loss of weight, diminished mobility in the breathing movements, and morbid sounds, were usually, in the hurry of seeing numbers of patients, considered by him as signs sufficiently indicative of phthisis pulmonalis. Now here was a case in which all these signs would have been found in a marked degree, yet the pathology of the case proved very different to the pathology of pulmonary consumption.

#### Dr. ROGERS exhibited an

#### ENLARGED HEART, WITH CALCAREOUS DEPOSITION.

The muscular fibre had undergone fatty degeneration. The age of the person from whom it was taken was 37. His history but imperfectly known, Dr. Rogers having been called in a few hours only before death. The patient then

complained of intense pain over the cardiac region, which he had suffered at intervals for six weeks previously. Difficulty, or rather oppression, in breathing, was also complained of. At the autopsy there was found effusion into the pericardium and right pleura, the left being bound down by old adhesions. The lungs were healthy. The other organs were not permitted to be examined.

Dr. COGSWELL read a communication

#### ON THE INFLUENCE OF HYDROCYANIC ACID ON THE LARYNX.

In experiments on frogs with hydrocyanic acid and other poisons, he had found, that in four or five minutes after the acid had been administered, and this whether it was given by the mouth or injected beneath the skin, the animals would keep the mouth open, when the inside was observed to be preternaturally florid. After death, which took place at an average in about two hours, the blood throughout the system was of a bright scarlet colour. But what most drew his attention was the state of the lungs, which were enormously distended, not collapsing when exposed. This led to an examination of the entrance of the larynx (aditus laryngis) which proved to be spasmodically closed. On its being pushed open with a probe, the lungs collapsed. On the other hand, in mammalia poisoned with prussic acid, the lungs are found to collapse, and the blood is dark. Could this difference be accounted for by the difference in the respiratory mechanism of the two classes of animals? The frog has neither ribs nor diaphragm, but forces the air into the lungs by the muscles of the throat, and expels it by the abdominal muscles. The lungs are little more than a pair of simple sacs. It has no epiglottis. The aditus laryngis is seen at the back of the mouth as a slit in a convexity formed by the two arytenoid cartilages. The muscles of the larynx in the batrachia, according to Mr. Bishop, are the dilator aditus laryngis and the constrictor aditus laryngis; besides which the tailless batrachia (the frog, &c.) have another called the compressor glottidis, which, as the author understood its functions, would cause the closure of the aditus. He suggested whether the arterial hue of the blood might not be occasioned by the unusual quantity of air in the lungs. In mammalia he had thought it possible that other appearances might be found after death, which would indicate whether the poison has a marked influence on the larynx and trachea. A dose having been given to a rabbit, in ten seconds it fell on the side struggling, in thirty seconds it uttered a cry, followed by a few gasping respirations, and after that it ceased to move. The lungs collapsed on being exposed, and presented nothing very remarkable, but the bloodvessels of the larynx and trachea were intensely congested. The author then proceeded to review the published accounts of the effects of prussic acid under the several heads of physiological, necroscopical, and therapeutical. First, it acted most rapidly when inhaled or injected into the windpipe. Disturbance of the respiration was included among the characteristic symptoms. Mr. Blake, in trying to fix the earliest period at which it begins to act, had found the effects retarded by introducing a tube into the trachea. M. Jorg and others, at Leipsic, when taking it for experiment, had suffered from bronchitis. Secondly, the post-mortem examination of the larynx and trachea had not been much attended to, but such evidence as existed was confirmatory of the present view. Mr. Taylor stated that these organs had been found reddened, but thought this might be due to accidental causes. In the seven epileptic patients mentioned by Orfila, who lost their lives, at Paris, in 1830, from an over-dose of the acid, a deep red colour of the larynx, trachea, and bronchi was among the post-mortem appearances. Thirdly, the diseases to which writers on prussic acid have paid most attention, are catarrhal and spasmodic affections of the larynx and trachea; and the eulogistic terms in which they speak of it are hardly paralleled in the history of medicine. After quoting the opinions of various eminent practitioners to this effect, the author concluded with observing that he thought there were sufficient data to sustain a probability that the larynx and trachea are the seat of a special action

under the use of prussic acid. He did not mean an exclusive action, nor would he enter into the question as to which element in the structure was chiefly concerned in causing the phenomena. As prussic acid seemed to be much employed to destroy useless animals, &c., the point under immediate consideration could soon be tested on a wide scale by other observers. If decided in the affirmative, this would be an important step, as giving precision to our inquiries concerning the kind of diseases in which it should be given, as a guide to the treatment of poisoning with the acid, and as an aid in medico-legal investigations.

Dr. LANKESTER read a very elaborate paper from the pen of Mr. Bishop, "On some of the principal Attempts which had been made to reduce the Phenomena of the Human Body to an Exact Science." The object of the author was to show that such attempts were praiseworthy, and though not successful to the extent which had been anticipated by their authors, had not wholly failed. In the course of his paper he gave a number of illustrations, in which this object had been sought by inquirers.—*Lancet*.

#### BIRMINGHAM PATHOLOGICAL SOCIETY.

##### OBSTRUCTION OF CARDIAC ORIFICE OF STOMACH BY A CANCEROUS TUMOUR. By Dr. FLETCHER.

WM. TARPLIES, married, aged 56, in the last degree of emaciation, was admitted, under my care, into the General Hospital, March 3, 1852. He states, that about eighteen months since (up to which time he had enjoyed uninterrupted good health) he had a violent attack of influenza, accompanied by a constant burning and aching pain in the epigastrium, not diffused, but limited to a circle of about three inches in diameter, which continued for about eight months, and during that time he had frequent attacks of vomiting whilst taking his meals. For these symptoms several blisters and mustard plasters were applied, which afforded him temporary relief. For the last ten months his stomach has been in an exceedingly irritable state, and rejected almost all the food immediately on being taken; and he has also had frequent attacks of vomiting of a clear, shiny, or frothy matter, occasionally tinged with blood, which was brought on by attempts to swallow, and sometimes even by any movement of the body. Occasionally the food was retained for one or two days, but produced much inconvenience of the epigastrium, and was succeeded by excessive vomiting, apparently of all the accumulated food.

His description accords very closely with the symptoms of disease he now labours under. As a general rule he vomits any quantity of food immediately it is taken, which appears to him to be stopped just at the bottom of the chest, and, when it is retained longer, vomiting of larger quantities of food invariably follows. Emaciation is extreme. There is no evidence of disease of the head, chest, or any tumour in the abdominal cavity, which was remarkably flattened, as if the stomach and intestines were completely empty. After having carefully examined for any evidence of an aneurismal tumour which might press upon and obstruct the œsophagus, and none being found, a bougie was passed down the œsophagus to the stomach with great care, but there it encountered some obstacle, and on withdrawing it, the end was found covered with blood and pus, with which also the vomited matters were tinged for some days after; but the patient experienced relief in swallowing food. From this it appeared most probable that there was a stricture at the cardiac orifice of the stomach, which was put down as the diagnosis. Food of a nutritious and farinaceous quality was ordered to be taken by teaspoonfuls at a time (and in this way he was more successful in retaining it), and injections of strong beef-tea. From this plan, he seemed for a time to derive benefit, but at length gradually sank lower, and a slight bronchitis was sufficient to terminate the scene. He died on the 25th of March.

A post-mortem examination was made twenty hours after death; body excessively emaciated; brain not examined; heart small, not above two-thirds of its normal

size, totally void of all fat, and presented a very varicose state of the veins all over its surface; the left lung was much engorged, and slightly consolidated at its lower part; the right lung was very emphysematous; oesophagus found healthy in its whole extent, it was neither contracted nor dilated until its termination in the cardiac orifice of the stomach; in the abdomen, around the cardiac orifice of the stomach (which was very much contracted equally in every way, so as to be like a stomach in miniature), was found a firm indurated mass about the size of a small orange, by which this aperture was contracted so as just to allow a swan-quill to pass through it; the end of the finger required force to be passed into it. On examination of the texture of this tumour under the microscope, cancer-cells were observed. The mucous membrane of the stomach and the pylorus were perfectly healthy; the muscular structure was very distinct; the intestines were healthy; the liver was much engorged, and presented the nutmeg appearance; the gall-bladder was not enlarged, but full of bile; the spleen and pancreas were healthy; the kidneys and urinary organs were perfectly healthy. The whole of the body appeared entirely free from fatty matter.

#### CASE OF DOUBLE STRANGULATION OF SMALL INTESTINE.

By Mr. SIMONS.

On October 2, 1851, at nine p.m., Mr. Simons visited a boy aged four years. Learnt that on the day previous the child complained of pain in the abdomen, and had vomited his food. The mother had given him some castor-oil, which was returned soon after; nor did any fluids taken remain on the stomach.

When seen at nine p.m., the countenance wore an anxious appearance; the eyes were much sunken; tongue furred; skin hot and dry; much thirst; bowels not relieved since the 30th (two days since); there was no swelling, nor any perceptible tenderness of the abdomen; pulse quick, jerking. Gave cal. & jalap. utiq. gr. iv. and febrifuge mixture every three hours. 3rd, ten a.m. The child worse; bowels not acted; frequent vomiting of the fluids swallowed. Gave cal. & jalap. gr. iij. every two hours, and administered an enema, which returned in the same state immediately. Five p.m. In the same state; slight tenderness of the abdomen. Ordered hot fomentations, and repeated enema, without effect. Eleven p.m. The same. 4th, nine a.m. Worse in all respects; vomiting constant; bowels not moved. Gave a warm aperient every two hours; repeated enema without effect. Five p.m. Much worse. Ordered wine and water frequently. Eleven p.m. The same. 5th, nine a.m. The child was evidently sinking; extremities cold; muttering delirium; faecal vomiting; bowels not yet opened; takes nothing but wine and water, which returns. Five p.m. Still worse. He continued in this state until eight p.m., when death terminated his sufferings.

*Sectio Cadaveris.*—A very remarkable double strangulation of the small intestines existed; it was formed in the following manner:—A knuckle of small intestine adhered closely to another portion of small intestine, apparently close to the root of the mesentery; this second portion of intestine passed under the adherent part of the first portion, at about four inches from the point of adhesion, and suffered constriction between the portion tied down and the root of the mesentery. Three feet four inches of intestine were thus involved; and the whole length was contracted to the size of a fetal intestine. At the termination of this length, the strangulated portion itself became the strangulating agent, by being tied down by lymph to the same portion of intestine which had first adhered; and it enclosed a knuckle of four inches belonging to the portion which caused the first obstruction, and not half an inch from the adherent point. So that all this length of nearly four feet of intestine formed a small mass, tied by two bands of adhesion, consisting of two loops—a large and a small one. The intestine around the constriction was covered with tolerable firm lymph. It was of a deep red colour up to the point where it was constricted; beyond this point it was pale.

#### FIBROUS TUMOUR INVOLVING THE CEREBELLUM.

By Mr. MOORE.

This preparation shows a fibrous growth, having its origin from the cerebellum. It passes more to the left side, and the cerebellum itself was found pushed upwards against the tentorium, very soft in structure, and containing bodies resembling, under the microscope, ill-formed pus globules. The tissue of the tumour itself appears, under the glass, to be composed of fibres radiating in various directions, with a scattering of nucleated cells. The subject from which the preparation was taken, was a man, aged about 40, who had long suffered from anomalous symptoms, referrible to the head. When admitted into the hospital there was very marked spinal gait; and he complained of shooting pains, particularly at night, in the regions of the ears and forehead. He never complained of occipital pain. He remained under treatment some weeks, until his death, there being no change in the symptoms, dissolution being preceded by great debility, and consequent inability to walk. He had always lived a moderate life, and never received a blow or other injury of the head.

#### SEPARATION OF THE FRONTAL FROM THE PARIETAL BONES, WITH DEPRESSION OF THE LEFT PARIETAL.

A man fell from a horse as he was proceeding at a somewhat rapid pace, and struck his head on some hard stones. On being seen an hour afterwards, the whole scalp was found much swollen, but by careful manipulation depression was found to exist near the left frontal suture. As the man was comatose, with dilatation of the opposite pupil, an incision was made through the scalp, and the depressed bone brought to its proper level. The immediate effect of this was relief of the stertorous breathing, and much less amount of dilatation of the right pupil; death, however, took place some fourteen hours after, and a large amount of blood was found extravasated both above and beneath the dura mater, with laceration of its structure, and also of the cranial substance in one place. The preparation shows the line of fracture and the depressed bone.—*Proc. Med. and Sur. Jour.*

#### ON THE EARLY SIGNS OF CONSUMPTION.

By THEOPHILUS THOMPSON, M.D., F.R.S.

It is a most important object to be able to detect the first approach of this deadly disease. It may be stated that one of the earliest signs which can be traced by auscultation is a modification of the expiratory murmur, consisting in an apparent prolongation, usually accompanied with an increase of coarseness.

The natural elasticity of the lungs is essential to soft and uniform expiration. When considerable consolidation is produced in their texture by tubercular or pneumonic deposit, bronchial expiration is produced; but between the healthy state and decided consolidation there are various intermediate conditions. When the pulmonary cells, as seen under the microscope, are only slightly thickened, and the glairy, grayish deposit, studded with little bright cells, characteristic of phthisical disease at an early period, is beginning to permeate the structure, bronchial expiration is not induced, but the diminished contractility of the cells, interrupted passage of air, and increased power of conducting sound, are sufficient to render the expiratory murmur more durable, coarse, and audible. In pursuing this investigation, be careful not to confound the inspiratory and expiratory movements with the inspiratory and expiratory murmurs. The duration of the two movements is nearly, if not exactly, equal. In the natural state the inspiratory murmur occupies the whole time of inspiration, but the expiratory murmur, at least to ordinary ears, only a fourth of the time of expiration, the remaining part of the expiratory movement being accomplished in silence. I believe the expiratory murmur follows the inspiratory immediately without a pause. With the progress of phthisis the duration of the inspiratory murmur usually lessens materially, though not necessarily in proportion to the prolongation of the expiratory; and some practice is ne-

cessary in order to acquire an aptitude in determining how much of the alteration depends on diminution of the duration of the inspiratory murmur, and how much on extension of the expiratory. You will find much assistance in estimating the relative duration of these sounds, by adopting a plan suggested to me by Dr. Sibson—namely, that of counting the number of strokes which can be given by beating time with the finger during the presence of each murmur respectively. The expiratory murmur, as disease advances, may gradually increase, until, instead of occupying, as in the natural state, a fourth of the period of healthy inspiration, it may even come to exceed in duration the inspiratory murmur.

You will occasionally find it stated, even in writings of some authority, that prolonged expiratory murmur is a sign of doubtful value, and not to be relied on; but when reasons are given for this assertion, you will find them unsatisfactory. If no symptom of disease were to be regarded which did not require to be accepted with some qualification, and interpreted with discrimination, the science of diagnosis would dwindle into childishness. What, then, are the cautions to be observed in attempting to deduce conclusions from the sign under consideration? You will best learn them by examples. In the man, B. H., now before us, you find the expiratory murmur equal in duration to the inspiratory, over nearly the whole chest; but the sound on percussion is for the most part clearer than natural, and the diaphragmatic ribs rather sink in than advance during inspiration. This patient has not an aspect nor a pulse characteristic of phthisis. His countenance is slightly livid, as though from imperfectly oxygenated blood; he has never had hæmoptysis. You see the pulsation of his heart in the epigastrium. Such a case you would never mistake for one of phthisis. You recognize it at once as one of extensive emphysema, and the prolonged expiratory murmur thence derives a ready explanation.

Take another patient in whom prolonged expiratory murmur is heard extensively, and indifferently at the lower and upper parts of the chest, but associated with sonorous and sibilant rhonchi. This is a case of chronic bronchitis. There is no circumstance to lead you to apprehend consumption. Again, you are probably aware that consolidation of lung in any part, from pneumonic or other deposit, may produce bronchial breathing, and the same cause, existing in a slighter degree, may induce prolonged expiratory murmur; but you will almost always find, in the constitutional circumstances, the history, the expectoration, and the other physical signs, enough to guide you to the correct interpretation. Let me contrast such conditions with those in which the expiratory murmur is modified by tubercular disease. In the patient whom I now introduce, P. D., you find, adopting the means formerly described, that the expiratory murmur at the apex of the left lung is equal to the inspiratory, each occupying the time required for five beats with the finger, and that the interval of silence is equal to two. Under the right clavicle the expiratory murmur might be represented by three: In other parts of the chest, expiration is not attended by any audible sound. There is no bronchial rhonchus, and the situation and degree of the phenomenon lead you to suspect phthisis. The movement of the chest is natural, and there has been no decided hæmoptysis; but I think you will be able to distinguish a slight degree of dulness when you strike the left clavicle, as compared with the right, and you will observe an irritable or quivering action of the intercostal muscles produced by a smart blow, which is worthy of notice as by no means uncommon in phthisical individuals. This patient has had a cough for six months; his expectoration is mucous, but, under the microscope, a few blood-globules may be detected. His height is five feet four inches; vital capacity by spirometer, 155 cubic inches, not quite a fourth less than the average for his height, and he weighs ten stone six pounds, having never, he says, exceeded eleven stone when in good health. These particulars, while they strengthen the conclusion to which you are led by the degree and place of the prolonged expiratory murmur, also serve to impress the value of the

sign, by showing that the disease is at a somewhat early period.

In the next patient, W. U., the sign being only on the right side, were it not considerable, would be inconclusive, on account of the greater audibility of the respiration on this side in the natural state; but it is so much prolonged, in this patient, as to exceed the inspiratory in length, the proportions being, four for the inspiratory murmur, five for the expiratory, and three for the interval of quiet. Furthermore, there is a little dry crepitation at the apex of the right lung. He has had occasional hæmoptysis, has declined in weight fifteen pounds during the last two years, and has almost lost his voice. The aphonia depending probably on a relaxed condition of the laryngeal membrane, we have applied medicines locally, by means of a slightly curved glass tube, as recommended by Trousseau and Belloe—if, indeed, we do not owe the original suggestion to Aretæus. In the first instance, we blew in alum, and subsequently nitrate of silver, mixed with twelve times its weight of sugar, just at the moment of inspiration. This mode of introducing medicinal agents into the windpipe is not, however, so easy and effectual as that adopted by Dr. Horace Green. This probang, having a soft, globular piece of sponge, capable of absorbing about twenty minims of water, very carefully fastened to the extremity, if very slightly curved, can be readily introduced under the epiglottis when passed steadily and firmly downwards, close by the root of the tongue. I usually employ a solution of two scruples of the crystals of nitrate of silver to the ounce of water, according to the recommendation of Dr. Green, and in relaxed and some other diseased conditions of the mucous membrane, the benefit derived from this measure is often considerable, although you would not be so unreasonable as to rely on such a measure alone, unassisted by judicious attention to the management of the general health.

One more case—that of J. C.—I bring before you, the sign in question being confined to the right side, with reference to the objection that prolonged expiratory murmur on the right side is consistent with health. In this patient, the expiratory murmur near the right apex is as five, and the inspiratory as four. On the left side, the expiratory murmur is not above a third of the inspiratory. This difference is too great to be attributable to natural conditions. You possibly detect slight dulness on percussion on the right side. He has had no hæmoptysis; but the pulse, which in the sitting posture is 80, is only 84 when he stands. He is nearly five feet seven inches high, and weighs ten stone two pounds and a half—a fair average for a man of his height. He has long had cough, but his constitution is scarcely at all affected, and but for his cough he would probably not have applied for medical relief. The disease is evidently at an early period; the symptoms, however, as far as they go, are definite, and the sign under our special consideration takes the most prominent place.

During the time of my attendance on the out-patients of this institution, I made this symptom an object of particular notice, and among 2000 consumptive patients, it proved to be the most remarkable of the physical signs, in 238, — those cases presenting bronchial complications being excluded. Hæmoptysis had occurred in 91 of these cases; that is, in 31 per cent.,—a proportion calculated to confirm my opinion of the significance of the prolonged murmur; and at the same time sufficiently below the average frequency of hæmoptysis in the first stage of phthisis, to support the assumption that the prolonged expiratory murmur takes precedence of other characteristic signs which are commonly assumed as requisite for the proof of consumptive disease.

With a view to the correct appreciation of the sign under our consideration, keep in mind the situation, degree, persistency and simplicity in which it is presented. Prolonged expiratory murmur slight in degree, if heard only on the right side, is inconclusive, but is far more significant if confined to the left. The more limited the space over which it is heard, the more does it suggest phthisis as the cause. The persistency of the sign for a considerable period, and unattended with symptoms of bronchitis, emphysema, or pneu-

monia, is a proof of some permanent obstacle to the free exit of the air, and in a majority of instances this obstruction is of a tubercular character. In cases depending on pulmonary congestion, the expiration, after cupping, and other appropriate treatment, usually resumes its natural character; but excluding this and other complications before noticed, I have not recorded any instance in which this sign, once fully established, ever ceased to be obvious.

Although, in many instances, no specific complaint was made, except of debility, and although, in this respect, improvement occurred under suitable treatment, it was yet common for the murmur to increase in duration, and deviate more and more from its natural character, whilst, sooner or later, dull percussion, bronchophony, hurried breathing, quick pulse, emaciation, and night perspirations, too often occurring in succession, afforded affecting testimony to the correctness of the first diagnosis.

A disturbed rhythm of murmurs, when established, I believe to be an unnatural condition, and the greater frequency of its detection on the right side may, I conceive, be readily explained; for if the respiratory sounds be naturally rather louder on the right side than on the left, the more delicate indications of pulmonary obstruction should first be detected in that direction. It would follow that in doubtful cases of apprehended phthisis, the absence of any changes in the expiratory murmur at the upper part of the right lung, would be a strong presumptive evidence of freedom from the disease. It is true that in certain individuals some degree of febrile action attends tubercular cachexy, before any local signs exist of tubercular deposit; but it has repeatedly occurred to me, when hereditary phthisis has manifested itself in a family, to be able, on examining the respiration of the surviving members, to prognosticate the approach of phthisis from this sign alone, in the absence of any other suspicious circumstances, either local or general. When the expiratory murmur is altered, in consequence of emphysema, or bronchitis, the extensive diffusion of the sign, and the other concomitant circumstances, will usually suggest a correct interpretation; and if we are careful to separate such sources of fallacy, I cannot but believe that the sign under review will prove no useless refinement, but one well deserving of careful attention, and perhaps the most early, significant, and conclusive of the evidences of incipient phthisis. It is no valid objection that the detection of the symptom requires close attention, since the object is to trace the first appreciable inroads of an insidious disease.

To sum up the conclusions to which the instances and statements now adduced, conduct us, I would observe that when the expiratory murmur is heard extensively, or on both sides, unassociated with bronchitis, emphysema, or condensed lungs, there is great reason to fear, not only that the disease is phthisical, but that it will make rapid progress. When the change of murmur is limited to a small portion of lung, and the general condition of the patient is favourable, the evidence of phthisical disease is fully as conclusive, but there is ground to hope that by careful regulation of diet, by securing exercise in the open air, by promoting healthy nutrition, and administering suitable remedies, such as iodine, iron, solution of potash, and cod-liver oil, more decided mischief may for a time be averted. I have reason to think that, under such circumstances, some years may occasionally elapse before softening takes place; and I cannot but believe that when this particular sign under consideration is more generally sought for in suspicious cases of phthisical tendency, the average duration of pulmonary consumption in persons possessing means to avail themselves of necessary comforts, will be found considerably to exceed the period commonly assumed.

The symptom which it is the object of this lecture to illustrate, must be considered to take precedence of various other rather early indications, which have been incidentally noticed in former lectures, such as an unduly diffused impulse of the heart, especially on the right side of the chest, or a murmur in the second intercostal space to the left of the sternum, which probably owes its source to the pulmonary artery. — *Lancet*.

## EMPLOYMENT OF MERCURY IN ORDINARY CASES OF SYPHILIS.

By G. BORLASE CHILDS, Esq.,  
Surgeon-in-Chief to the City Police Force, &c.

DURING the ulcerative stage of an ordinary chancre, I believe there are few practitioners who would place their patients under the influence of mercury; such a practice would be fraught with danger, and, to say the least of it, the progress of the case would be slow, and much more protracted than it ought to be; circumstances both embarrassing to the surgeon and unsatisfactory to the patient. If, therefore, an opportunity occurs of seeing the patient during the earlier stage of chancre, the right course will be to destroy the pustule by a liberal use of the nitrate of silver, or, what is far better, with a finely pointed stick of caustic potash; less irritation will be found from the latter application than the former; the sore should then be treated with simple dressing, or with a weak solution of chloride of soda and opium, over which a layer of finely-carded cotton should be placed, in order to obviate the possibility of friction. This treatment should be pursued until the regenerative process commences, when mercury may be resorted to with marked benefit. These sores are not unfrequently contracted at a time when persons, having drunk more freely than prudence suggests, a sort of artificial incentive is acquired for sexual indulgence. With these persons the system is in an irritable, inflammatory state, and the sores so contracted necessarily assume an irritable, inflammatory type. Under such a state of things, it would not only be unwise, but dangerous, to place a patient under a course of mercury—we must wait until the system has been cooled and quieted by mild aperients and opiates, the sore freely cauterized, and subsequently dressed with the solution referred to. It will sometimes be necessary even to abstract blood from the sore itself by the application of a leech, care being taken that an additional chancre is not created from the leech-bite itself.

In spite of all our efforts, from the onset some sores pertinaciously resist every attempt made to heal them, and evince a disposition to rapid ulceration and sloughing, to which we apply the term phagedæna. Some of these are of a superficial, others of a deeper character; many are amenable to the influence of mercury, but there are others, again, in which this remedy totally fails, and in the treatment of which large doses of iron and opium can alone be depended upon. It is but rarely that the surgeon is enabled, at first sight, from the appearances of such sores, to form a correct judgment of the plan of treatment he ought to adopt, whether mercurial or otherwise; but granting that the sore had a venereal origin, and that the patient had not been previously submitted to a mercurial course, with certain restrictions, he would not err in adopting it. In short, as a general principle, mild doses of mercury, in the form of blue-pill and Dover's powder, may safely be tried in all ordinary cases of venereal chancre, without any ill result.

With regard to the second question—viz., the influence of mercury over venereal sores, there can be little doubt but that a great many of these sores heal without the aid of mercury; and there can be still less doubt but that a modified mercurial treatment greatly facilitates the healing process, and materially diminishes the chances of secondary symptoms. Were I asked, therefore, to define the character of a sore in which the simple treatment should on no account be risked, I should say, in a few words, all sores that have a tendency to induration and an indisposition to heal. And here I may also remark, that if we are disposed to be exclusive in the use of this remedy, we must learn to distinguish those sores which derive their induration from simple irritation, and those which acquire it from the application of a specific virus, as all the characteristic appearances of a true Hunterian chancre are not unfrequently simulated in a similar sore by a too liberal use of lunar caustic and other irritating applications.

And now, as to the power of mercury in preventing constitutional syphilis—a question of grave importance to the

patient, and one of undoubted interest to the surgeon—a question which I am free to confess has not been satisfactorily responded to in my own mind, either by my own personal experience or by the collated opinions of others, to place implicit confidence in the antisiphilitic powers of mercury; or, during the primary chancre, to guarantee a patient's safety in this respect, would be but a bold and adventurous speculation, and one unbecoming a follower of legitimate practice. Certainly much can be done to lessen the chances of such a result, by judicious management in the early stage of chancre, such as free cauterization, rest, and a proper prophylactic treatment. It has been asserted by a celebrated writer on this disease, that all persons are not susceptible of a general infection. In this opinion I concur; and it must have been observed by those who have had much experience in this department of practice, that persons who, from neglect or otherwise, have not touched a grain of mercury, yet with a sore possessing all the characteristics of a true Hunterian chancre, are never attacked by consecutive affections; while, on the other hand, those who from the commencement have been submitted to a mercurial course, have suffered most severely from them. In such an uncertain state of things, the wisest course is to avoid extremes by steadily administering moderate doses of blue-pill, combined with Dover's powder, until the sore has healed, and no induration remains. By this plan, although we cannot offer our patient a sure guarantee against constitutional infection, yet there is one thing at least we shall have the satisfaction of knowing, that should consecutive affections appear, in the majority of cases they will be so modified and mild in their character, that little or no uneasiness need be felt respecting the results.—*Braithwaite's Retrospect.*

#### LIGATURE OF THE LARGE ARTERIES IN EIGHTY-TWO CASES.

By M. Roux.

THE following eighty-two operations comprise the whole number of ligatures of arteries performed by M. Roux since 1808, and were communicated by him to the Société de Chirurgie:—

Popliteal artery..... 1	1 Spontaneous aneurism (ancient operation).
	3 Recent wounds.
	2 For hæmorrhage after gunshot wounds.
	2 Wounds of artery in operation.
	7 Hæmorrhage after amputation.
Femoral artery..... 46	1 Femoral aneurism (Hunter's operation).
	2 Femoral aneurism (ancient operation).
	2 Fungous tumour of tibia.
	27 Popliteal aneurism (Hunter's operation).
	10 False aneurism of the bend of the arm.
	6 Arterio-venous aneurism.
Brachial artery..... 20	2 Hæmorrhage after amputation.
	1 Spontaneous aneurism of the ulnar artery.
	1 Fungous tumour of the radius.
	1 Fungous tumour of the orbit.
Carotid, common.... 6	2 Wound of the face.
	3 As a precautionary measure before operations.
Axillary, immediately below the clavicle..... 4	1 Spontaneous aneurism.
	1 Recent wound, with false aneurism.
	2 Hæmorrhage after amputation at the shoulder-joint.
Subclavian..... 3	Secondary hæmorrhage.
External iliac..... 2	Secondary hæmorrhage after ligature of the femoral artery.
Total..... 92	

In these operations the digital mode of Brasdor has not been tried. The old method 16 times; and that of Hunter,

with Scarpa's ligature, 66 times. The number of cases of true aneurism was 33, of which two only were women. The results were, 10 unsuccessful and 23 cures. The number of false aneurisms was 10, all of which were successfully treated.

Of the six cases of arterio-venous aneurism, for which the humeral artery was tied in each case, four were successful, and in two amputation was necessitated by gangrene or secondary hæmorrhage.

These statistical facts will be read with interest by the English surgeon, by whom the thick ligature used by Scarpa is now carefully eschewed, but the small number of cases (4) in which secondary hæmorrhage occurred, will certainly bear out M. Roux in his attachment to this mode of operation. The difference between the English and French modes of conducting the ligature of arteries is so great, both in the operation itself and in the dressing of the wound, that we rejoice to find that the above facts will form part of a complete work on surgery, which M. Roux is now preparing, and of which the memoir presented to the Société de Chirurgie is only an instalment.—*L'Union Médicale and Prov. Med. and Sur. Jour.*

#### POPLITEAL ANEURISM SUCCESSFULLY TREATED BY COMPRESSION.

By Mr. CRITCHETT.

A HAWKER, aged 32, in the habit of gaining his living by selling salt about the streets, was admitted into the London Hospital, under the care of Mr. Critchett, in the middle of May, 1852. The patient had recently suffered from a severe attack of laryngitis, but was gradually recovering, having been under medical treatment for the affection prior to his coming into the hospital.

A large aneurism occupied the lower and inner part of the left thigh, and extended somewhat forwards and backwards, internally, to the median line of the limb. The lowermost part was on a level with the upper border of the patella, and the highest extended to about the inferior part of the middle third of the thigh. The sac altogether gave the idea of being about the size of a small shaddock; the cyst felt thin, and the thinnest part was in front and internally, in which situation the integuments were dark, as though from a slight amount of subcutaneous ecchymosis. Pulsation was everywhere distinct, and a bruit de soufflet, though not very loud, was audible, being, however, more distinct over the track of the popliteal artery than elsewhere. Both these conditions ceased on pressure being made on the femoral artery, the tumour at the same time somewhat diminishing.

The compression treatment was systematically commenced on the seventh day after the admission of the patient, and followed out in a similar manner to that pursued in a case of popliteal aneurism which was cured by this method, under the care of Mr. Ward. Before the apparatus was had recourse to, the nature of the treatment, and the mode of carrying it out, were explained to the patient. The sheets, mattress, and pillows on which he lay, were firmly fixed to the bed-frame, and the square pad on which the left limb, in a state of partial eversion and flexion, was placed, was also firmly attached; and at the bottom of the bed a large pillow was secured by bandages, and served as a *point d'appui* for the right foot, so that any gliding of the body could be avoided. A large cradle was placed over the body, in order that the bed-clothes should not interfere with the proper action of the instruments. One drachm of acetate of potash was ordered to be taken three times a day; the patient was placed on middle diet, without beer, and was requested to drink as little as possible. The hair was shaved from off the skin over the pubis and the middle of the thigh, and the integument dusted over with flour.

A variable and occasionally interrupted pressure was maintained on the femoral artery for eight days, through the medium of a four-pound meat weight (acting on a common tourniquet pad) to the groin; and a clamp at the thigh, applied at two distinct parts—the one two inches

above the upper boundary of the aneurism, the other a little higher. The weight at the groin and the clamp were alternately used. The former instrument was kept on sometimes for an hour, at others for only half an hour; and prior to its being removed, the clamp was usually adjusted, and kept on for a period ranging from five to fifteen minutes.

During these eight days, the patient slept four or five hours each night, the pressure being of course not so uniformly kept up as during the day, but the same method being followed out as far as possible. On the fourth day after the first application of the instruments, a small superficial vessel could be detected pulsating along the inner border of the patella; on the fifth and sixth, the patient had a sensation of pins and needles over the upper part of the tumour, which latter had become much harder, less in size, and sensibly hotter than the surrounding parts. The pulsation on the sixth day was just perceptible; and on auscultation, only an impulse, like the first sound of the heart, but much more feeble, was detected.

On the seventh day, the hair was again removed from the groin and middle of the thigh; and on the eighth, the pulsation in the aneurism had entirely ceased.

Between the fifth and eighth day, four or five small vessels were detected pulsating in the vicinity of the patella. On the ninth day after the aneurism was cured, a small superficial vessel was observed running over its centre. The pressure was continued for a week after all pulsation in the tumour had ceased; and the patient became an out-patient in the beginning of July, having been in the hospital fifty-two days. There was a good deal of œdema about the leg when he went out, but this gradually subsided after careful bandaging.—*Lausset.*

#### NAVAL MEDICAL SERVICE.

(Continued from Students' Number, p. 265.)

Admiralty Office, Somerset House.

*Director-General of the Medical Department of the Navy.*

Sir William Burnett, K.C.B., K.C.H., M.D., F.R.S.

REGULATIONS—DATED AUGUST 1, 1850.

THE Lords Commissioners of the Admiralty have directed "that no person be admitted as an *Assistant-Surgeon* in the Royal Navy, who shall not produce a certificate from one of the Royal Colleges of Surgeons of England, Edinburgh, or Dublin, or from the Faculty of Physicians and Surgeons of Glasgow, of his fitness for that office; nor as a *Surgeon*, unless he shall produce a diploma, or certificate, from one of the said royal colleges or faculty, founded on an examination to be passed subsequently to his appointment of assistant-surgeon, as to the candidate's fitness for the situation of surgeon in the navy; and in every case the candidate producing such certificate, or diploma, shall also undergo a further examination before the Director-General of the Medical Department of the Navy, touching his qualifications in all the necessary branches and points of medicine and surgery for each of the steps in the naval medical service." Previously to the admission of assistant-surgeons into the navy, it will be required that they produce proof of having received a preliminary classical education, and that they possess in particular a competent knowledge of Latin; also,

That they are of good moral character, the certificate of which must be signed by the clergyman of the parish, or by a magistrate of the district.

That they have served an apprenticeship, or have been engaged for not less than six months in practical pharmacy.

That their age be not less than twenty years, nor more than twenty-four years; and that they are unmarried.

That they have actually attended an hospital in London, Edinburgh, Dublin, Glasgow, Aberdeen, or Manchester, for two years subsequently to the age of eighteen, in which hospital the average number of patients is not less than 150.

That they have been engaged in actual dissections of the human body twelve months; the certificate of which

from the teacher must state the number of subjects or parts dissected by the candidate.

That they have attended lectures, &c., on the following subjects, at established schools, by physicians or surgeons of the recognized Colleges of Physicians and Surgeons in the united kingdom, for periods not less than below stated; observing, however, that such lectures will not be admitted if the teacher shall lecture on more than one branch of science, or if the lectures on anatomy, surgery, and medicine be not attended during three distinct winter sessions of six months each:—Anatomy, eighteen months; or general anatomy, twelve months; and comparative anatomy, six months. Surgery, eighteen months; or general surgery, twelve months, and military surgery, six months. Theory of medicine, six months; practice of medicine, twelve months. (If the lectures on the theory and practice of medicine be given in conjunction, then the period required is eighteen months.) Clinical lectures (at an hospital as above) on the practice of medicine, six months; on the practice of surgery, six months. Chemistry, six months; or lectures on chemistry, three months; and practical chemistry, three months. Materia medica, six months. Midwifery, six months, accompanied by certificates stating the number of midwifery cases personally attended. Botany, six months; or general botany, three months; and medical botany, three months. N.B.—Six months' lectures on pathology, if given at a university where there may be a professorship on that branch of science, will be admitted in lieu of six months' lectures on the practice of medicine.

In addition to the tickets for the lectures, certificates must be produced from the professors, &c., by whom the lectures were given, stating the periods (in months) actually attended by the candidates. The time, also, of actual attendance at an hospital or infirmary must be certified.

A favourable consideration will be given to the cases of those who have obtained the degree of M.D. at Oxford, Cambridge, Edinburgh, Dublin, Glasgow, London, or Aberdeen; or who, by possessing a knowledge of diseases of the eye, and of any branch of science connected with the profession, such as medical jurisprudence, natural history, natural philosophy, &c., appear to be more peculiarly eligible for admission into the service; observing, however, that lectures on these or any other subjects cannot be admitted as compensating for any deficiency in those required by the regulations.

By the rules of the service, no assistant-surgeon can be promoted to the rank of surgeon until he shall have served three years (one year of which must be in a ship actually employed at sea), and can produce a diploma from one of the before-mentioned royal colleges, or the faculty of physicians and surgeons, and it is resolved that not any diploma or certificate of examination from either of the aforesaid royal colleges shall be admitted toward the qualification for surgeon, unless the diploma or certificate shall be obtained on an examination passed after a period of not less than three years' actual service; observing that no one can be admitted to an examination before the director-general for surgeon, unless, as hereinbefore mentioned, he can produce a diploma, together with the most satisfactory certificates, that he has performed on the dead body, under the superintendence of a professor or teacher of known eminence, all the capital operations of surgery, and is perfectly competent to perform any operation with skill and dexterity, and thoroughly acquainted with the anatomy of the parts involved in such operation; without which qualification, no one hereafter can be promoted to the higher branches of the service; and whenever assistant-surgeons already in the service (whose professional education may not be in accordance with the above) obtain leave to study previously to their passing for surgeon, they will be required, on their examination, to produce testimonials of their having availed themselves of the period of leave to complete their education agreeably to these regulations generally.

Candidates who may be admitted into the naval medical service, must serve in whatever ships, &c., they may be

appointed to; and in the event of their being unable to do so from sea-sickness, their names cannot be continued on the naval medical list, nor can they of course be allowed half-pay.

By an Admiralty Circular, dated July 17, 1850, assistant-surgeons are to be divided into two classes. The first class to consist of all who have completed three years' servitude from the period of their first entry (one year of which must be served on board a commissioned ship, and the other two may be served in one of the naval hospitals), and who have passed their examination for surgeon either at home or abroad. "Assistant-surgeons who have served more than three years, and have passed the examination for surgeon under the above conditions, are to rank next to naval instructors, and are to mess with the board-room officers, to be allowed cabins when the accommodation and space on board will admit." The second class of assistant-surgeons to consist of all those who have not served three years, and those who have not passed their examination for surgeon. First class assistant-surgeons, who may be serving in small vessels commanded by lieutenants, are to mess in the guard-room with the other officers.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, NOVEMBER 3, 1852.

### DUBLIN SCHOOL OF SURGERY.

#### OPENING OF THE SESSION AT THE ROYAL COLLEGE OF SURGEONS.

A sketch of Dr. JACOB'S "Introductory" must content our readers in place of our usual "Leader." The learned Professor (all professors are learned) began by reminding his audience that he had last year endeavoured to keep up their drooping spirits, and to dispel an apparent despondency then prevalent touching medical affairs, by assuring them that prospects were brightening, and that, as the popular phrase has it, a "better time was coming." He now had to take credit for his predictions, for it was admitted on all hands that the condition of the country had improved; that confidence in its resources had been more or less restored; and that prosperity, if not absolutely attained, was at least talked of. He said, too, that rents were better paid, poor rates diminished, and the labourer's wages raised. Moreover (he observed) that the potato rot had repeated its visit, but out of that misfortune we might derive consolation, seeing that, notwithstanding, no apprehensions of famine were entertained. Some of his hearers, he said, might stare, if they pleased, at his prefacing an Introductory Lecture in a Surgical School with such observations as these; but he did so, because he wished to remind those now entering the profession, that upon the prosperity of the people must depend their prosperity; and that it behoved those who were to live by the public to consider well the means from which their remuneration was to be derived. He wished also to expose to beginners the realities of professional life, and to fasten their attention upon the reward for which they were to toil. Whatever course they pursued to achieve it, the ultimate object must be a comfortable livelihood and a respectable position in society. It might do very well for aspirants to metropolitan medical honours and profits to indulge in ambitious hopes of future celebrity, and to suppose themselves HUNTERS, COOPERS, and COLLESES in embryo; but the great mass of Medical Students, especially those from the provinces, must think of the main chance, and eschew building castles in

the air; for they might rely upon it, few amongst them were destined to attain celebrity; neither, perhaps, was it so very desirable that they should. Be that as it may, the Student was here now to learn how to discharge the duties for which they are to receive that payment which is to constitute their means of existence, and it was his business to explain how that was to be accomplished. Before entering into details on that topic, he would, however, say a few words as to their prospects of success, and the good things in store for them. He would first say a few words on the subject of the public employments they might hope to partake of, reminding them that public situations were valuable; first, for their pecuniary benefits; secondly, for the character which they secured; and thirdly, for the improvement derived from the performance of the duties which they entailed. Of the pecuniary advantages offered by public situations, he said he was sorry to say he could not boast much. They were altogether disproportioned to the services performed; but still the beginner should not despise them. They all knew that a great change had taken place with respect to the Medical Institutions of Ireland, and that in many cases great injustice had been the result as to the salaries of Surgeons of Dispensaries, but that he was not, on the present occasion, about to offer any suggestion promising a remedy for the grievance, which must be sought for elsewhere. He had now to remind the rising generation of Surgeons that, be the remuneration in store for them good or bad, it was not altogether unworthy of consideration. Fifty pounds a year for a Dispensary Surgeon was a miserable stipend; but counting up all the salaries paid for medical services in Ireland, he found that about one hundred thousand pounds were distributed in this way, derived from local taxation exclusively. There were now 777 Dispensaries, 163 Workhouse Hospitals, and between thirty and forty County Infirmaries and general Hospitals, which, with what remains of an hundred Fever Hospitals, and the Lunatic Asylums and Prisons, not less than a thousand public situations were reserved for Irish Surgeons who deserved them, and they were worth working for. Such (he continued) was the money part of the question; he had next to remind them of the advantages which such situations afforded, by enabling the holders of them to acquire character, the great means of securing independence. It was unnecessary to urge arguments to prove that character was to be won by success in public practice, however humble the department; there was no question about that. If the Surgeon cured the labourer or the servant in the course of his dispensary labours, he must soon come to cure the master, mistress, and children. But, then, here was a two-edged sword; bad characters might be had as well as good; ignorance and incapacity would as surely lead to failure and ruin, as knowledge and skill led to success and prosperity. Here was the place to tell them that. In the medical treatment of internal diseases, errors and blunders might be concealed. Dead men told no tales; but surgical delinquencies were not to be overlooked. Bleeding arteries, strangulated intestines, and dislocated joints, must be properly dealt with, or shame and sorrow must follow. That the improvement to be derived from hospital and dispensary practice was of the utmost value, was equally undeniable; there, in fact, it was that the Surgeon had to learn his business by the aid of experience; there it was that he discovered he was always a Student; and the best of the thing was that, be he ever so idle or negligent, he must learn whether

he likes it or not. But (he observed) you may ask me, what is to become of those who cannot obtain these appointments? and his answer is, make them for yourselves. While you wait for public employment and remunerative practice, keep your hands and heads in working order by attendance on your poor neighbours; rely on it that you will find plenty of patients, if you pay attention to them. But where, you will say, is the medicine to come from? On that score there is little difficulty. When you know more about the matter, you will discover that disease in general may be encountered by less numerous weapons than you now suppose; in fact, a man can carry all he wants at this stage of his career in his pocket. Time was that there were no Dispensaries in Ireland, and yet the poor were not without medical relief. The Surgeon then (and he served his time to one of them) carried a pouch slung over his shoulder under his coat containing calomel, tartar emetic, laudanum, jalap, and a few other indispensables, and with these he contrived to do a great deal. This was not, however, a thing to be talked about out of doors. He, however, wished it to be understood, that he was not addressing himself to gentlemen destined for practice in large towns or cities where a very different course was to be pursued; what he wanted, was to convince the candidate for country practice that he may be independent, if he will. If he acquires the knowledge, he may rest assured that he will find no difficulty in turning it to account. Home employments were not, however, the only ones in reserve for Surgeons. Since he last addressed them another channel had been found into the great ocean of civilization. The gold discoveries had created a new description of emigration and change of country which could not be effected without its medical ingredients. The emigrant ship must have its provision for medical relief as well as the union or the workhouse, and for such service they should hold themselves in readiness. He hoped that there is no fear of their being deterred from this by any groundless fears of personal dangers; but he feared there was a want of spirit of enterprise amongst them which their humbler countrymen at the present moment so conspicuously displayed: why not take a leaf from the Scotchman's book; Sawney is always "ganging sooth;" and let them select another point of the compass. If the old people counsel caution and prudence, let them be told that it is easier now to reach New York than it was to reach London when they were children. Allusion was made to the Army, Navy, and East India Company's Service, as affording employment to educated Surgeons, but our limits do not permit us to report them. Neither can we find room for some pertinent observations on the policy of holding England in view as a field for cultivation; in fact, we cannot, at present, find room for much important matter contained in the concluding portion of the Lecture relative to Surgical Education, and the means provided for the communication of professional knowledge, which we regret the more, because it contained some unequivocal expressions of opinion as to sham diplomas. On this topic it may suffice to state, that a very decided announcement was made to the effect, that no body of men in Ireland, whether incorporated by charter or not, had any legal right or power to grant a licence to practise Surgery, except the College of Surgeons; and that any attempt to exercise such a power was to be looked upon in the same light as those acts which both individuals and corporations sometimes perpetrate without the sanction of authority or the approbation of honest men.

## MEDICAL LIFE IN LONDON.

SCHOOLS AND HOSPITALS.

London, October 25, 1852.

It does one good sometimes to laugh at the pervading follies of the hour—along with the Dublin School, for instance—to talk over our pale ale and glycerine absurdities, Bethlem jobs, royal colleges, and quarantine. You have been too severe, however, with our tea parties. It is all very well to say "the tender lamb that never nipped the grass" is not more innocent of complicity with the enemies of bitter ale;" but why abuse our muffins and tea, premiums and introductory? The profession, indeed, going to the dogs; but our schools and diplomas paying admirably. Everybody, not a political economist, is reading "Uncle Toni's Cabin," and you must recollect the teapot is there immortalized as a "sort of censor of hospitality and good cheer." Why, then, should our first-year's men, being all strangers, not be—ahem!—taken in? why should our young men (the wretched trading chemists engrossing all the practice in the meantime) not be told of a profession the paths of which are all pleasantness and peace, strewn with flowers of the olive by our royal colleges? quackery (reigning as a plague, at least in London) kept quietly out of view. Why should our young men at Bartholomew's not undergo the killing equinoxial politeness of Mr. Lawrence, the tall benediction of Mr. Green at St. Thomas's, the easy jocularly of Mr. Luke at the London Hospital School, the unwinking snuff-box assiduity of Mr. Cock at Guy's, and in every available and possible shape be induced to join the serried ranks of the profession. Would to heaven, the pupils who give up their lives and all they are worth to medicine, were there to make anything by it; not the *sans souci* quacks who laugh at colleges and Medico-Chirurgical Society bitter-nesses and black beans.

Any one who has felt any interest in these ramblings among the Schools, will recollect we spoke before of Guy's and St. Thomas's, with a look-in occasionally at King's College and Brompton. We would say a few words again of St. Bartholomew's, as having "come out" perhaps strongest at the recent opening of the Session, and being, *longo intervallo*, the oldest, and perhaps most extensive, along with its "twin cousin," Guy's, of any of the Schools. We are quite aware, in this fine Californian age, there is little advantage in being a sort of dressing-gown and slippers *banshee*, bemoaning the miseries of the profession. Individually we have no interest in the question, but let us at least know the truth that royal colleges and diplomas are not what the profession requires at the hands of parliament, but that royal colleges should act some little way in conformity with the requisites of the age. Alcaics and irreproachable Latin—hexameters on the mountains of the moon at Oxford and Cambridge—epics, eclipsing Milton, on Woolwich Marshes or the Isle of Dogs, at the London University, leave many men without a means of living. A superstitious veneration for our royal colleges and diplomas—worth in England exactly nothing—leave also many men without bread, at the mercy of every miserable quackery. It seems very much like common sense if we have a surgical college at this side of the channel underselling the more respectable College of Surgeons' diploma of Dublin: that at least this College will not neglect its pariahs, its outcasts, and thus foster every variety of charlatanism. In "Bleak House" there is a church beadle "too respectable" to permit the poor to go to church; we suburbanly suspect our friends in Lincoln's-inn are far

"too respectable" also to look after their hapless members. We want uniformity in our *curricula*; we want our Dublin College of Surgeons consolidated and made more firm, not distracted and picked to pieces; and we want our London College of Surgeons made precisely similar to it. No smuggling or underselling of diplomas. The public have some defined notions of what a tailor is, or haply what constitutes a bricklayer, but none whatever in England of a surgeon; the blue-bottle man next door to the confectioner, with no diploma or education of any sort, is the surgeon; the surgeon, possibly a railway porter, or singer at the next tavern, is the "Member of the College" and representative of Pott and Hunter.

The Introductory at St. Bartholomew's has led us into this train of observations. St. Bartholomew's the Little, you must know, is a divine little parish with three houses, a church, and no poor-rates. Tea parties in such a community must be the normal condition of the population. Poor Dr. Black, therefore, did his best to look grave; but we have an inherent infirmity in believing, if the miserable condition of the profession were not what we have, with sadness, attempted to sketch it, his labour of praising their prospects to the pupils would be much abbreviated. Every man of sense in London feels that the profession is what it ought not to be, yet at the Westminster School, Dr. Bashnan gave as his Introductory the history of medicine from the alchemists down to the homeopaths; of the marvels worked by the microscope, and of chloroform. At Charing-cross School, Dr. Smith gave a lively lecture on the Duke of Wellington. At St. George's, Caesar Hawkins read a homily on the untold virtue of giving prizes: all matters as germane to the prospects of the poor pupils as last year's snow. At the London Hospital, Dr. Herbert Davies, with more sense, but too much bashfulness, enlightened our whitebait friends with an excellent lecture, containing many trenchant cuts at quackery; but at poor old St. Thomas's, again we were disappointed by a lecture on London cess-pools and sewers by Mr. Grainger. Your Dublin Introductory, we trust, will take a more practical shape: why not give us specimens next week in the *MEDICAL PRESS*?

One is gratified to find, if we are to have philibeg M.D.'s in tartan petticoats shodling over the land from Aberdeen and St. Andrew's, that we may as well have a few who wear shamrocks on the part of your patronising saint, St. Patrick. Of one thing everybody may be certain—the system of clinical education and lectures in Dublin is far better and more practical than that in London; our "crack" men here have all too much business to do to mind the pupils, especially the first-year's men; and one branch of the profession, most creditably taught at the Rotundo in Dublin, midwifery, is here almost unknown: a *terra incognita* for pupils, where they may ramble at their own free will.

At Bartholomew's, perhaps, we may say the junior men are the most thought of. Mr. Skey is adored by the pupils, much more so than either of the seniors, Mr. Lloyd or Mr. Stanley; while Mr. Wormald, with much of the manner of Abernethy, is a greater favourite still than any of the dons; and Mr. Paget, though the last of the juniors, like those favoured in the kingdom of heaven, is the first man in the hospital. Mr. Lawrence, with an equanimity of some fifty years' growth, is only too polite and condescending. We mentioned before, that Bartholomew's had 600 beds and 6000 patients annually; here,

then, one would think there was "ample room and verge enough" for some brilliant practice. Bartholomew's, we may mention as a matter of historic interest, was founded far back in the night of the 12th century, and is the oldest hospital perhaps in London; it was founded by Rahere, a minstrel, it seems, to Henry I., and connected with his foundation of the church and nuthell parish of St. Bartholomew's; in the words of the foundation—"Ad omnes pauperes infirmos ad idem hospitale confluentes, quousque de infirmitatibus suis convalescerint." &c. Subsequently, at the period of the Reformation, among the few good deeds of Henry VIII., we read that he took possession of Bartholomew's, and after ten years' thinking over the matter—as long almost as Smithfield under its walls seems pending in spite of Mr. Grainger of St. Thomas's—he decided on refounding the hospital and giving it a royal charter with certain princely emoluments (what a pity he did not try his hand with your Dublin hospitals), "moved thereto (the words are curious, and only a little too much like things in Ireland) with great pity for and towards the relief and succour and help of the poor, aged, sick, low, and impotent people now lying and going about begging in the streets of the city of London . . . infected with divers great and horrible sicknesses and diseases." At this time the hospital contained only 100 beds, one physician and three surgeons. In France, somewhere about this time, as we mentioned before, they were throwing the sick into the Seine alive, the king tucking up his regal trousers and asking as a favour that the population would clean their houses.

The subsequent history of this hospital is almost that of the profession itself, and deeply interesting. One would have thought, with the barber element so strong in the surgery of the last generation, and physis, *à la* homeopathy just now, being entirely with old women and archbishops, that the attendants at Bartholomew's were obscure and unknown—a motley assemblage, like—what shall we say?—the surgeons in a state of incubation in Trinity College; or, yes! that's it, the many-coloured assemblage of fellows made spick and span new in Lincoln's-inn this week at so much a head. Not so, however. In the dark obscurity of the past, whatever we shall say of the present, Bartholomew's has stood out a sort of beacon-light along the deep; and Harvey, Radcliffe, Mead, Freke, Pott, Pitcairn, and Abernethy, speak for themselves. For many years after the charter, Vicary, surgeon-general to Henry VIII., to Mary, and Elizabeth, and who, it is stated, published the first English work on anatomy, filled the office of surgeon; he swam with the tide, and is now unknown, for to be misunderstood is the fate of all great men. Clones and Woodhall, the Crampton and Guthrie in military surgery of the time, followed Vicary; and now came poor, noble Harvey, appointed physician to Bartholomew's in 1609, an office which he held for the immense period of thirty-four years, but which he gave up, dying, according to the good London fashion, in utter neglect and obscurity. We talk of Harvey's beautiful discovery of the circulation every day, but at college lectures and Bartholomew tea parties, one's heart bleeds for the man. We recollect the king assisting him in his experiments and fostering his genius, but the book-shops and doctors abusing him.

About the middle of the 17th century, pupils first commenced attending Bartholomew's, and a library of some nebulous form appeared on the horizon, "for the use of the governors and young university scholars;" no doubt

containing Vicary's Anatomy, Ben Johnson, Hippocrates, and the Fires of Smithfield; not the *Times* and *Athenaeum*, now so amiably displayed, or Quain's Anatomy, thumbed to pieces, or the last lists from Tattersall's, which all dutiful first-year's men, in default of something else, are intended to read. We must not be too severe with our friends of the Abernethy-tea-and-biscuit-Society however. Poor fellows, they little know the troubles their cheap diplomas are engendering for them; and that their luck consists in that we have not diplomas for 18s. 4d., as the memorable one in Tristram Shandy. Their great gun, young Mr. Skey, may have astonished them with a tournaquet of his own invention, and the *Lancet* gentleman may have taken the trouble of giving it a week's immortality; but he should have known a carpenter in Dublin discovered it before him, and that Dr. Bellingham, in his excellent little work, gives a summary of everything known on the subject. Several gentlemen from America and from Paris have been lately poking into the recesses of Bellingham's book: but at Bartholomew's, *c'est un autre chose*. The library at Bartholomew's is now very respectable; but to go back again to "Uncle Tom's Cabin," Mr. Skey the elder, like Dinah the cook, cares nothing for authorities—"No possible amount of authority, of talent, or explanation, can ever make him believe that any other way is better than his own." Dinah believed a cook, like a king, could do no wrong; Mr. Skey believes the same of a Bartholomew's man. It is true, no conservative of any school is more inflexibly attached to time-honoured inconveniences—mercury in every form of syphilis, to wit—than some of his patriarchal *collaborateurs* in the Bartholomew attics. In the "chaos and old night" up there, the men of the Ricord schism have no chance; but then it is all St. Bartholomew's, you know, and quite in an overpoweringly polite way all right. Mr. Skey talks of "half a century ago when he was in Paris," so he is not very young; but he is the great lion of the pupils. He replaces Mr. Paget as lecturer at the College, and will no doubt make a most useful and able lecturer. But we must not anticipate.

In 1724, at a time when Radcliffe and Meade were attached to Bartholomew's, the first museum was erected and placed under the charge of Freke, surgeon to Queen Anne; and in 1734, leave was first granted to "read lectures in anatomy in the dissecting-room of the hospital." This was ably followed out by Percival Pott and Nourse, and about the same time the Pitcairns also lectured, it is thought, on medicine; but a greater star was now breaking in the not very sunny sky of Bartholomew's; and, in 1787, Abernethy was made assistant-surgeon. Abernethy's fame has reached everywhere. He was what Sir Astley Cooper was at Guy's, Cheselden at St. Thomas's, and what Sir Benjamin Brodie is at St. George's. Sir Benjamin Brodie and Mr. Lawrence are indeed the connecting links of the present and the past in what is great in the profession. Were their views of what is gentlemanlike and correct in medicine more observed, and mere trading speculations in cheap diplomas less encouraged, and unlicensed practice put down, our colleges would be doing more honour to the great memories of the men of the past, than by the untold classicalities of Harveian and Hunterian orations, and miserable shams taking the name of Introductory Lectures. When medical men in England, in a word, take their proper place among the other professions, and medical journals tell of the beautiful facts in medicine springing up on every side, not engage in low scurrilities worthy of

butchers' boys, every one will feel pleasure, and the more obscure he is now the better. In engaging in a study which engaged the fine minds of Harvey, Hunter, and Jenner—the martyrs of their various creeds—like poor Sir Roger de Coverley, in the *Spectator*, musing among the dead heroes in Westminster Abbey, there is something not entirely without interest in looking at the relics of our dead men in Bartholomew's. But who shall make the present and future of surgery equal to the past, give a to bowl

#### LAST ILLNESS OF THE DUKE OF WELLINGTON.

THE Duke of Wellington was supposed to be in his usual health until the morning of the day of his death; how far this opinion may be correct will subsequently appear. He had been engaged until dusk of the preceding evening in reading the report of the Oxford University Commission, and did not suspend his labours, until compelled by inability to distinguish the print; having at the time noticed the light on the opposite coast, he observed that it was the "darkness," and not the failure of his sight, which caused the print to "bother" him. He dined heartily shortly afterwards, at seven o'clock, and took for dinner mock turtle-soup, turbot, venison, and pudding. As was his usual practice, he drank neither wine nor spirit. He retired to bed before ten o'clock, and during the night visited the closet. The appearances found there showed that whilst the functions of the bowels were healthily performed, the Duke, contrary to his habit, must have returned hastily to bed, probably in pain. His Grace's valet, Mr. Kendal, who called him at his usual hour, shortly after six o'clock, observed that his master was not well, and that his breathing seemed oppressed. His Grace not appearing disposed to get up, his attendant, after remaining some time in the room, left him until half-past seven. Returning at this time he was directed by the Duke to send for "the apothecary." (This he (Mr. Kendal) immediately did, and Mr. Hulke of Deal was in attendance about nine. He found his Grace complaining much of pain across the chest, and at the pit of the stomach; his tongue was furred; he had distressing eructations, and his pulse was irregular. It was intimated by Mr. Hulke that he would send a draught, and he recommended that his Grace in the meantime should take a little warm tea and toast. Mr. Kendal endeavoured shortly afterwards to act on this recommendation, but the Duke seemed unable to swallow the tea. He became sick, and threw up a portion of the venison which he had taken the evening before. This piece of meat had not been altered in appearance by the process of digestion. A general convulsive attack ensued, of some minutes' duration. After the fit, the Duke to some extent recovered his consciousness. He laid on his back, his favourite position when in bed, with his hands clasped, and placed at the back of his head, his eyes occasionally following persons in the room. Mr. Hulke was immediately sent for again, and speedily returned, accompanied by Dr. McArthur. His Grace had another, but less severe convulsive attack, between eleven and twelve o'clock. Further medical assistance was sought for from London, and telegraphic messages were sent to Dr. Hume, who had long been the medical attendant of the Duke, to Dr. Robert Ferguson, a friend of Dr. Hume, and to Dr. Williams, who alone of the three happened to be in town, but who unfortunately, did not arrive till the Duke had for several hours ceased to live. This lamentable event occurred a few minutes before half-past three o'clock. After the first convulsive attack, the Duke's exhaustion rapidly increased, and his breathing became much embarrassed; he had slight twitchings in one arm, but no paralysis. When an effort was made to give him either medicine or drink, his Grace generally exhibited reluctance to take it, pushed away whatever was offered to him, and showed his usual dislike to be interfered with. The treatment employed consisted of a mustard poultice applied to the pit of the stomach by the valet; a mustard emetic, partially administered, and without action; a dose of calomel and small quantities of stimulants were offered to the patient, but were not swallowed. For some time before his death, his Grace had been removed to a chair, to relieve the difficulty of breathing; but the medical attendants finding that his pulse, already extremely feeble, became in that position, still weaker, his Grace was again restored to the recumbent posture. During some days preceding the 14th of September, the day of the Duke's death, there had been a hot midday sun, a considerable wind, chiefly from

the north, and the evenings and nights were cold and chilly. The thermometer, on the night preceding the fatal event, was only six degrees above the freezing point; on the preceding day, it had been up to 92 deg. No precautions were taken to obviate the effects of such a change on the aged and necessarily weak system of the Duke; and the pallor of his countenance observed on the preceding Sunday, showed that this influence was telling on the circulation. The stomach was thus ill prepared to receive a hearty dinner; and the difficulties of that organ were further increased by receiving a considerable quantity of food imperfectly masticated, in consequence of the Duke's loss of teeth. Nor was the process of digestion promoted, or the powers of the stomach and heart invigorated, by the use of stimuli. The stomach therefore contained a mass of undigested food, and became distended with flatus; the functions of the lungs were impeded; the heart's action was disturbed; the nervous system participated in the morbid processes going on; and as a child would have convulsions under similar circumstances, so had the Duke of Wellington, who, becoming exhausted by the disturbed and enfeebled condition of his nervous and circulating systems, rapidly sunk and expired. Why or wherefore such an attack should be called "epilepsy," we are at a loss to conceive. The certificate of death, at least as it has appeared in the journals, is not correctly expressed. It is probable that had the Duke's stomach been relieved by vomiting in the early part of the morning, he would now be with us; it is even possible that such an effort, if successful at nine o'clock, might have saved him; but every hour added to the exhaustion, and rendered such an act more difficult.—*Lancet*.

Tuesday, September 14th: About half-past eight this morning, my father received a note from Walmer Castle, stating that the Duke of Wellington wished to see him. He immediately went to the Castle. His Grace complained of uneasiness about the chest and stomach; was then perfectly conscious, and answered questions put to him with correctness. Some medicine was ordered, and during its preparation his Grace took some tea and toast. Shortly after leaving the Castle, my father received another communication, stating that his Grace was much worse; he had had fits similar to those he was subject to. My father and I went directly, and found his Grace in bed, unconscious; eyes turned a little upwards, fixed; pupils of medium size; skin warm and moist; respiration very laborious, from accumulation of mucus in air tubes. Before our arrival his valet had applied a mustard poultice to his chest, as on a former occasion this had given relief.

Dr. McArthur soon arrived, and Drs. Hume and Ferguson were telegraphed for.

Dr. McArthur advised a mustard emetic to be given, having prescribed one with advantage several years ago under similar circumstances. This and other measures were now of no avail. His Grace became very restless, tried to turn on his left side; occasionally there were slight twitchings of the left arm. When raised in bed, his breathing was much more free, and this induced us to place him in an easy chair, when his respiration became much less embarrassed; his pulse sank, and his Grace was now placed more horizontally; the pulse rallied for a little time, and then gradually declined; the breathing became more feeble; and at twenty-five minutes past three o'clock p.m., his Grace breathed his last. So easy and gentle was the transition, that for the moment it was doubted. A mirror was held before his Grace's mouth: its brightness was undimmed, and he was no more!

JOHN WHITAKER HULKE.

## MIDWIFERY REFORM.

It may not perhaps be generally known, that by recent regulations of the Council of the Royal College of Surgeons, a Board of Examiners in Midwifery has been established, consisting of the senior vice-president of the college, together with Dr. Arthur Farre, Dr. Henry Oldham, and Dr. James Reid. The conditions under which candidates are admitted have just been published, from which it appears that persons who are, or shall become fellows or members of the college prior to January, 1853, will be admitted to examination on production of their diploma; other gentlemen becoming members subsequently to the above date, will be admitted on producing, with their diploma, a certificate of having attended twenty labours. From the same regulations, it appears that members or licentiates of any legally constituted college of surgeons, or graduates in surgery of any univer-

sity requiring residence to obtain degrees, will also be admitted to examination on producing, with their diploma, certificates of being twenty-one years of age, of having been occupied four years in the acquirement of professional knowledge, of having attended one course of lectures on midwifery, and of having attended not less than twenty labours. There are other regulations on the above important subject, which may be ascertained on reference to the secretary at the college.

This salutary change has not been made before it was wanted. It is to be hoped that the Irish College will follow the example here set, for nothing can be conceived more scandalous in the diploma trade than this department has exhibited. The moment is favourable, and should not be lost.

## SALE OF SHAM PRACTICES.

To those contemplating the purchasing of partnerships or "practices" in England, the following warning or caveat emptor will prove useful. That an English practitioner can sell his patients is wonderful, but still more wonderful that a shadow can sell shadows:—

We have known of instances—of cases indeed which could now be pointed out—in which men, failing to get into good practice, have devoted themselves with surprising ingenuity to the fabrication of practices upon paper, for the mere purpose of selling partnerships and successions. Cases of this kind occur, in which the perpetrators of the fraud take in (in a double sense) a partner every two or three years, and live in the intervals, upon the proceeds of the repeated sale of a partnership in a practice which exists only in a sham ledger. No sooner is a dupe found to deposit a few hundred pounds, than the payment of a temporary income takes place to him out of his own money; but the fraud is soon detected, a quarrel ensues, and the junior partner is glad to get free from the connexion, which can only bring disgrace. One case has occurred within our knowledge, in which a young medical man, duped of all his property, had to threaten a bill in Chancery before he could dissolve the partnership with the fellow who had cheated him. The following is the mode in which these sham practices and partnerships are prepared for sale. A labourer has his head broken in a drunken frolic; he is entered in the day-book as Mr. Doctor Esq. and daily visits, pills, draughts, lotions, and dressings, are entered with all due parade, and a heavy bill is drawn out in place of four times as many pounds, five shillings are taken in discharge of the attendance, but £20 are set down in the books as the amount of the bill delivered and discharged. When labourers are not forthcoming, imaginary patients are recorded, and imaginary bills are carried to the account of the practice. Not long since, we saw an assistant who had fairly run away from a person who was required as part of his daily work to create an appearance of practice in this manner. Of course such mistreats are rare in the profession, but they do exist, and create more misery than will readily be conceived. Such men think less of getting honest practice than of making up a case for future retirement or sale of practice. These hats will be sufficient for young men who are more inclined to get into practice suddenly, by the purchase of a partnership or succession, than by years of persevering labour and good conduct. They should learn that sharpers beset the short paths to position and income. For the sharpers themselves, exposure will be the fitting punishment. After due warning, no man should negotiate for "partnerships" or "successions" without sound guarantees of the honesty and characters of the parties with whom he has to deal. These will be of far greater consequence than the inspection of books and accounts.—*Lancet*.

## BOURN v. COX.

The council of the Bath and Bristol Branch, in accordance with an unanimous resolution, have convened a special general meeting of the members, to be held at the Royal Western Hotel, Bristol, to consider if any and what steps should be taken in consequence of the verdict given on the trial—*Bourn v. Cox*. And also to consider the propriety of publishing such a letter on medical subjects, in a public newspaper, as was recently done by Mr. John Barrett, in the case—*Bourn v. Cox*.—*Prov. Jour.*

## THE VALUE OF "EM. DEE."

We copy the following by way of comment on a disputed point in medical history. It is evident that there is a difference of opinion as to the comparative value of past and present medical honours. Doctor-making, however, becomes every day more and more expensive. To make seven of less than ordinary dimensions here in Dublin the other day cost "the country" a cool thousand. But, then, seven marvellously learned gentlemen, whom Senates delight to honour, pocketed the best part of it. Men of merit are sought after, as Falstaff says:—

In your last number, I read an insulting and arrogant letter from an individual who once considered himself "a connecting link between the profession and the aristocracy," but who now appears to be smarting under a non-appreciation, or more probably a due appreciation, of his merits by a discerning public. He says he has reflected on the cause of this, but, having come to a wrong conclusion, I wish to put him on the right scent. The time has long gone by when the mere circumstance of wearing a white cravat, and assuming an air of gravity, even although backed by a carriage and pair, and an L.R.C.P. Lond., will obtain the confidence of the public, who are daily becoming less disposed to take "omne ignotum pro magnifico," and who have the good sense to prefer one who, in addition to a sound professional education, has had extensive practical experience at the bedside, to one whose professional knowledge is obtained almost exclusively from books, his practical experience being 0, notwithstanding all his efforts to obtain it by means of the "advice gratis" system; or puffing his work on a disease of which he has probably never had a case under treatment. For the body of pure physicians generally, I entertain great respect, many of them being men whose general attainments, profound professional knowledge and acumen, entitle them to the highest confidence of the profession and the public; but there are unworthy members of this as well as of the other branches of the profession, and of these I could, from personal knowledge, say much, but for the present forbear. With reference to your correspondent, it is a pity to see a man pretending to "polite education" and "superior attainments," use words of which he does not know the meaning, although so common-place that any charity schoolboy could explain them to him. To "assume" means to claim unjustly; and "bastard" means spurious. Consequently, those terms cannot be applied to any one who has attained the degree of M.D. from a university legally empowered to confer it; they can only be applied to those who dub themselves M.D. without possessing any legal right to do so, although they may be licentiates or extra-licentiates of the R.C.P. Lond.; and there are many such, some of whom, subsequently to obtaining this licence have been rejected at the Apothecaries' Company, as well on account of their deficient knowledge of Latin, as from general professional ignorance. So much for these gentry of "polite education" and "superior professional attainments." As regards the affix M.D. used by those legally empowered to do so, it is an insult to common sense to consider it amiss to append it, any more than the use of M.A., D.D., &c., by the humblest individual of the profession to which he may belong. The remissness of the Colleges of Physicians and Surgeons having compelled the general practitioner to become connected with a trading company (an anomaly which exists nowhere but in England) it is right and praiseworthy that those members of this body who are legally authorized to use the title of M.D., should do so, and proclaim to the world that, although compelled by law to become connected with a trading company, their inclination and their attainments have associated them with a university; and I think you will agree with me, that although every member of the medical profession were to use the prefix of Dr., it would no more affect the "social estimation and position" of those pure physicians whose attainments entitle them to occupy a high place in the profession, than the affix of M.R.C.S., as at present almost universally used, affects the "social estimation and position" of a Brodie, a Fergusson, or a Syme.—  
Letter in *Lancet*.

## TO CORRESPONDENTS.

We have fallen into arrear in our account with several correspondents from press of business during the last two weeks, which we propose to discharge without delay. In the case alluded to by "A Fellow of the College," was the party in question in office previous to the passing of the act, but we have a review of his services in our next number.

## MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

At a meeting of the Central Committee, held in the Royal College of Surgeons, October 28, 1852,

The President of the College in the chair, a letter was read from Dr. Duncan, sen., of Farnham-house, Finglas, enclosing a donation of £100.

Resolved, That the Secretary be requested to communicate to Dr. Duncan the cordial thanks of the committee for his munificent donation, and to express how much the society is indebted to him, not only for this, but also for the generous assistance he has afforded to it from its foundation.

A letter was read from Dr. Erskine, Secretary to the Newry Branch, enclosing £10 9s. from the following members in that district—viz., Dr. Davis, £1 1s.; Dr. Morrison, £1 1s.; Dr. Molloy, £1 1s.; Dr. Johnston, £1 1s.; Dr. Starkey, £1 1s.; Surgeon Black, £1 1s.; Surgeon Savage, £1 1s.; Surgeon Gray, £1 1s.; Surgeon Waddell, £1 1s.; and the Secretary, £1 1s.

A letter from Dr. O'Rourke of Enniscorthy, enclosing £1 1s. and announcing the formation of a Medical Society for the county of Wicklow, "one of whose resolutions pledges it to appropriate a portion of its funds annually to the Medical Benevolent Fund Society of Ireland."

Signed by order,

CHARLES BENSON.

M. W. HANLON, M.B.

### THE MEDICAL CHARITIES ACT: TIPPERARY UNION.

At a Meeting of the Medical Officers of Dispensaries in the Tipperary Union, held at Tipperary on Saturday, the 30th of October, for the purpose of considering the propriety of looking for an increase of Salary, and the measures to be adopted for that purpose.

Dr. JOHN RYAN, Thomastown Dispensary, in the chair,  
Dr. BRADSHAW, Bansha Dispensary, Secretary,  
it was resolved—

That the salaries fixed in this union, £60 a year, are quite inadequate remuneration for our time and labour, that sum being little more than sufficient to cover the expenses of man and horse which we are obliged to keep for those duties; that when it is considered that all our time is, by the Commissioners' regulations, at the disposal of the committees, and that we are liable to be called upon at any hour of the night, it will appear quite evident that such salaries are by no means a fair or just remuneration.

Resolved—That it is advisable that such committees in this union as are favourable to an increase of Salary, be requested to communicate with the other committees on the subject, and also to send a deputation to the Board of Guardians.

Resolved—That the minutes of our proceedings be forwarded to every medical man in the counties of Tipperary and Limerick, and the adjoining unions, and that they be requested to attend a General Meeting of the Profession, to be held at Thurles, at Boyton's Hotel, on Saturday, the 13th of November next, at One o'clock, to consider the entire subject, and the propriety of forming an association.

Signed, JOHN RYAN, M.D., Chairman.

### SCHOOL OF ANATOMY, SURGERY, AND MEDICINE OF APOTHECARIES' HALL, IRELAND.

Cecilia-street, Dame-street.

#### THEORY AND PRACTICE OF SURGERY.

Mr. ELLIS will commence the Winter Course of Lectures on the Theory and Practice of Surgery in this School, on Wednesday, the 3rd of November, at Three o'clock, and continue to lecture at the same hour, on Mondays, Wednesdays, and Fridays, to the end of the Session.

Mr. Ellis will, in his Introductory Address this Day, explain the Working of the Medical Charities Act, and point out the injustice done to the great majority of the Medical Officers of the Dispensaries in the rural districts throughout Ireland by the manner in which it has been administered.

Mr. Ellis's information on this subject is derived from the most authentic sources, and is based upon facts which cannot be controverted.

### HOSPITAL SULPHATE OF QUININE, PURE CRYSTALLIZED.

Prepared by EDWARD HERRING, of the late firm of HERRING, Brothers, for the use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure, its form of crystal is the same and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is unbleached and the other bleached. It was originally introduced for the use of Hospitals, Dispensaries, and public Charities, but its purity and great reduction in price is attracting the attention of Medical Men and the Dispensing Chemists.

It is put up in bottles (free) of three ounces and six ounces each, capsuled, with the name of the Proprietor, and labelled with the name of the Inventor. The peculiar mode of preparing the unbleached and white sulphates is being made the subject of a patent, and will shortly be made public.

Both articles to be had of the leading Druggists in London and the united kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor.

Chemical Works, Trinity-street, Southwark, London.

October 23, 1852.

### THE PHARMACEUTICAL JOURNAL (Nov. 1), CONTAINING THE TRANSACTIONS OF THE PHARMACEUTICAL SOCIETY.

CONTENTS:—The Adoption of the Title Pharmaceutical Chemist.—To the Parents and Guardians of future Pharmaceutical Chemists.—The Abuse of Chemical Certificates: The Beer Puff.—The Scientific Institutions of Birmingham.—Pharmaceutical Meeting.—Distribution of Prizes.—On the Mode of conducting the Pharmaceutical Meetings.—On a Disease in Wheat.—Meeting at Birmingham to consider the Pharmacy Act.—Drugs observed at Aden, Arabia.—Pavon's Collection of Peruvian Barks.—Extract of Colocynth and Compound Colocynth Pill.—Report upon Original Gravities.—Researches on the Colouring Principle of Urine.—The Fluorescence of Quiniferous Solutions.—The Quantity of Alkaloids contained in many Cinchona Barks.—Hospital Sulphate of Quinine.—Patent Heat regulating Plaster Spatula.—Felt and Chamois Leather Plasters.—Specimen Bottle for Chemical Preparations.—The Bouquet of Wine.—Litmus.—Blacking.—The Prohibition of the Sale of Coffee mixed with any other Ingredient.—Mr. Dawson's Handbill, &c. &c.—With an extra Half-sheet. Price 1s.

London: John Churchill, Princes-street, Leicester-square;  
Edinburgh: MacLachlan and Stewart; Dublin: Fannin and Co.

\* \* Volume XI. may be had in boards, as well as the preceding volumes, price 12s. 6d. each.

G. OLDHAM and Co., *Pharmaceutical Chemists and Apothecaries*, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

### THE COMPOUNDING DEPARTMENT AT G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.  
G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

### SHIRTS CUT BY MACHINERY.

#### WEBB AND CO.'S

New System of Shirt-cutting by Machinery enables them to produce really First-class Shirts at prices lower than they have ever yet been offered.

Their Eglinton Shirts,  
at 2s. 6d., 3s. 6d., and 4s. 6d. each,  
are accurately Cut, elegant in Design, and perfectly sound in Fabric.

A large assortment of Fancy Veined Full-dress Shirts always on hand.

THE TAILORING AND GENERAL OUTFITTING  
WAREHOUSES  
are now most extensively supplied with every description of  
WINTER CLOTHING.

THE READY-MADE DEPARTMENT  
contains an immense variety of  
Top Coats, Travelling Coats, Wrapper Coats, Pilot and Frieze Pea Coats,  
at 15s., 17s. 6d., and 20s. each,  
which, for Workmanship and Solid Value, are not and cannot be surpassed.

WEBB AND CO.,

10, 11, and 12, CORN-MARKET.

**SCHOOL OF SURGERY.**

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**

WINTER SESSION 1852-53.

THE Dissecting-rooms opened on the 1st of October, and the Lectures commenced on the 25th.

Anatomy and Physiology—Dr. Jacob.  
Descriptive Anatomy—Dr. Hart and Dr. Power.  
Surgery—Mr. Porter and Mr. Hargrave.  
Practice of Medicine—Dr. Benson.  
Chemistry—Dr. Barker.  
Midwifery—Dr. Beatty.  
Comparative Anatomy—Dr. Jacob.  
Dissections by the Professors of Anatomy and the Demonstrators—Dr. Leeson, Mr. T. D. Hargrave, Mr. Malcomson, and Mr. J. Morgan.

**SUMMER SESSION.**

Materia Medica—Mr. Williams.  
Medical Jurisprudence—Dr. Geoghegan.  
Botany—Dr. A. Mitchell.  
Practical Chemistry—Dr. Barker.  
The fee for each of the above Courses is two guineas, except Comparative Anatomy, which is free.

A public course of lectures on Comparative Anatomy and Zoology, free to all students, is delivered by the Professor of Anatomy and Physiology at the commencement of the session, and additional lectures on the same subject at intervals during the winter.

Practical instruction in Operative Surgery is given by the Professors of Surgery, separate from the surgical lectures. Fee, £5 3s.

The Professor of Chemistry receives operating pupils into the Chemical Laboratory.

The following Ordinance was made by the Council of the College on the 9th of April, 1851:—"To enable surgical students to devote more time to hospital attendance and dissection during the winter session, the lectures on materia medica, medical jurisprudence, practical chemistry, and botany, shall be delivered during the summer session in the school of the College, and in the schools recognized by the College; and certificates granted subsequent to the 30th of April, 1851, shall not be received as qualification for Letters Testimonial, unless issued in conformity with this regulation." Similar regulations have been adopted by the Council of the College of Surgeons of England.

*Hours of Lecture:*

Descriptive Anatomy—Twelve o'clock every day.  
Chemistry—One o'clock, Mondays, Wednesdays, and Fridays.  
Anatomy and Physiology—Two o'clock every day, except Monday.  
Surgery—Three o'clock, Tuesdays, Thursdays, and Saturdays.  
Practice of Medicine—Three o'clock, Mondays, Wednesdays, and Fridays.  
Midwifery—Four o'clock, Tuesdays, Thursdays, and Saturdays.  
Dissections from sunrise to sunset; one or more of the Demonstrators being always present to give instruction.

The Professor of Botany will commence a course of lectures on Structural and Physiological Botany in February. This course, taken in conjunction with that on Comparative Anatomy and Zoology, by the Professor of Anatomy and Physiology, constitutes the course of Natural History required by the Army Medical Board.

Pupils attending the Lectures on Midwifery and Diseases of Women and Children are admitted to the practice of a recognized midwifery hospital on payment of a fee of £4 4s.

The Professor of Medical Jurisprudence gives practical instruction in Toxicology in his Laboratory.

**PRACTICE OF PHYSIC.**

Dr. BENSON will commence the Course of Lectures on the Principles and Practice of Physic in the Royal College of Surgeons on Wednesday, the 10th day of November, at Three o'clock p.m.

The Description, Pathology, Diagnosis, and Treatment of Medical Diseases will form the subject of the Course.

Pathological Preparations, Plates, and recent Specimens of Diseased Parts, will be exhibited for the purpose of illustration. The Lectures will be delivered on Mondays, Wednesdays, and Fridays, throughout the session, at Three o'clock.

N.B.—Gentlemen entering the Army are required to attend Two Courses of Lectures on the Practice of Medicine; and those entering the Navy to attend Three such Courses. Fee for each Course ... Two guineas.

**CITY OF DUBLIN HOSPITAL,**  
*Upper Baggot-street.*

The Winter Session commenced on Monday, October 25.

The arrangements of this hospital are such as to afford the student an opportunity of studying disease in all its forms—Medical and Surgical. The morning visit commences daily at half-past eight o'clock, when the nature, treatment, and progress of each case are explained at the bedside of the patient, and ample opportunity afforded to every pupil of becoming practically acquainted with the uses of the Stethoscope. Clinical Lectures are delivered after the hospital visit.

Connected with the hospital is an extensive Dispensary, at which the pupils are allowed to perform the minor operations, under the guidance of the surgeons, and are rendered familiar with the details of dispensary management.

Every facility is given to students desirous of acting as Dressers and Clinical Assistants, subsequent to which all pupils of the hospital are eligible to the situation of House-Surgeon, according to merit.

A distinct course of Lectures upon Diseases of the Eye is delivered by Dr. Jacob, which the pupils are privileged to attend, without additional fee, and special wards are appropriated for the reception of Eye Cases. Extended opportunities are thus afforded for acquiring a thoroughly practical knowledge of this important subject.

A ward is appropriated to the Diseases of Females, and clinical instruction is given upon all forms of Uterine Affection by Dr. Beatty.

Mr. Tufnell's course of Lectures upon Military Surgery is also open to the pupils of the hospital. This course is recognized as equivalent to six months' surgery in the professional qualification of candidates for admission into the Army, Navy, and Ordnance Medical Departments, and is required to be attended by all gentlemen entering the Hon. East India Company's Service.

A Lending Library of well-chosen books has been provided for the use of the pupils; and a correct Registry of the cases in hospital is kept by the House-Surgeon, to which they have free access.

Certificates of attendance on this hospital are recognized by all the Colleges, Universities, and Halls, and by the Army and Navy Medical Boards.

Fee for Winter six months	...	Six guineas.
" Summer six months	...	Four guineas.
" Nine months	...	Eight guineas.

*Medical Attendants.*

A. Jacob, M.D., Fellow and Professor of Anatomy and Physiology, Royal College of Surgeons, 23, Ely-place.  
T. E. Beatty, M.D., Fellow and Professor of Midwifery, Royal College of Surgeons, 18, Merrion-square, North.  
C. Benson, M.D., Fellow and Professor of the Practice of Medicine, Royal College of Surgeons, 34, York-street.  
W. Hargrave, M.D., Fellow and Professor of Surgery, Royal College of Surgeons, 37, York-street.  
R. G. Williams, M.D., Fellow and Professor of Materia Medica, Royal College of Surgeons, 14, Lower Fitzwilliam-street.  
T. G. Geoghegan, M.D., Fellow and Professor of Forensic Medicine, Royal College of Surgeons, 52, York-street.  
J. Tufnell, Esq., Fellow of the Royal College of Surgeons, 58, Lower Mount-street.

*Consulting Physicians.*

Sir Henry Marsh, Bart., and Professor Apjohn.

*Consulting Surgeons.*

Sir Philip Crampton, Bart., Professor Porter, and J. W. Cusack, M.D.

For further particulars apply to Dr. Benson, York-street.

**DISEASES OF THE EYE.**

**DR. JACOB** will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

THE

RICHMOND SURGICAL, WHITWORTH MEDICAL,

AND

HARDWICKE FEVER HOSPITALS,

North Brunswick-street.

The Course of Attendance and Clinical Lectures at the above mentioned Hospitals will commence on Wednesday, the 3rd of November, 1852, at eleven o'clock a.m., when Dr. Corrigan will deliver the Introductory Lecture. The Course will be continued during the Winter and Summer Sessions.

These Hospitals contain 300 beds, and have attached to them the Talbot General Dispensary, the Lunatic Asylum at Island Bridge, and the Truss Establishment for the Relief of the Ruptured Poor of Ireland; also a well-selected Medical and Surgical Library.

There is also an extensive Museum, containing nearly four thousand Morbid Preparations, Casts, and Drawings, available for clinical instruction, and always accessible to the hospital class.

The Surgeons visit daily at half-past eight o'clock, and the Physicians daily at ten o'clock a.m.

Two Surgical and two Medical Clinical Lectures will be delivered in each week.

The Resident Pupils and Clinical Clerks of the Richmond, Whitworth, and Hardwicke Hospitals are selected from the class, according to merit.

Two Prizes will be given at the end of the Winter Session—one in Clinical Surgery, and one in Clinical Medicine.

The Instruction in Clinical Medicinæ is given by—

**Dr. Corrigan, M.R.I.A.,** Physician in Ordinary to the Queen in Ireland, Lecturer on the Practice of Medicine in the Carmichael School of Medicine, &c.;

**Dr. Banks, M.R.I.A.,** Honorary Fellow of the King and Queen's College of Physicians in Ireland, King's Professor of the Practice of Medicine, Physician Extraordinary to the Richmond Lunatic Asylum;

**Dr. McDowell, F.R.C.S.I.,** Lecturer on Anatomy and Physiology in the Carmichael School of Medicine, &c.;

**Dr. Gordon, F.R.C.S.I., M.R.I.A.,** Physician to the Government Lunatic Asylum at Island Bridge.

The Instruction in Clinical Surgery is given by—

**Dr. Hutton, M.R.I.A.,** President of the Royal College of Surgeons in Ireland, Surgeon to Simpson's Hospital, &c.;

**Dr. Adams, F.R.C.S.I., M.R.I.A.,** &c.;

**Mr. Hamilton, F.R.C.S.I., M.R.I.A.,** Examiner in Surgery to the Queen's University, Lecturer on Surgery in the Carmichael School of Medicine, &c.;

**Dr. R. W. Smith, F.R.C.S.I., M.R.I.A.,** Professor of Surgery in the University of Dublin;

**Dr. Christopher Fleming, F.R.C.S.I., M.R.I.A.,** Surgeon to the Netterville Institution, &c.

In the immediate vicinity of these Hospitals is the Carmichael, late the Richmond Hospital, School of Medicine, where regular Courses of Lectures are delivered on the several subjects of medical science.

Attendance for nine months on the practice of a general hospital, with attendance on the clinical lectures on medicine and surgery therein delivered, is, by a recent regulation of the Board of Trinity College, required from candidates for the degree of M.B.

The London College of Surgeons require a list of the pupils entering for the Winter Session to be transmitted to their Secretary, on or before the 25th of November next.

**Terms of Attendance.**

For the Winter Session of six months,	Eight guineas.
For the Summer Session of three months,	Three guineas.

For further particulars apply to the Secretary, Dr. Hutton, 29, Gardiner's-place, or at the Hospitals.

**MILITARY SURGERY.**

**Mr. TUFNELL** will commence the Course of Lectures on Military Surgery in the Theatre of the City of Dublin Hospital on Tuesday, November 16th, at Four o'clock p.m.

This Course is recognized as equivalent to Six Months' Surgery in the professional qualifications of Candidates for the Medical Departments of the Army, Navy, and Ordnance; and by an Order of the India Board, dated March 1, 1852, is rendered imperative upon all Gentlemen educated in Ireland, who may hereafter seek admission into the Hon. East India Company's Service.

### THE PATHOLOGY OF INFLAMMATION AND FEVER.

By H. FREKE, A.B., M.B., M.R.I.A.

(Continued from page 102.)

(*The Function of Nerves continued.*)

#### THE VOLUNTARY MOTOR APPARATUS, ETC.

AT the close of my last communication, I was desirous of directing the reader's attention to the contemplation of *certain* relations which I conceive may be perceived to subsist between what have been termed "matter" and "mind,"—between the objects in surrounding material creation and the perishable and the *permanent* part of our mental constitution. I was desirous, in other words, of directing that attention—1st, to the contemplation of the *manner* in which the objects in surrounding creation are related to and connected with the *material* part of our being; upon which the *development* or manifestation of what are termed "mental phenomena" is dependent; that is, to the nature of the relation in which the objects referred to stand towards those organized structures or residual products (collectively named "cerebral matter") which have been constructed by Nature with the special end or design of giving development or manifestation to what are termed "mental phenomena;" and 2nd, I desired to direct that attention to the contemplation of surrounding material creation in its relation to that principle of our existence which (be its nature what it may) may be regarded as the *fountain or source* of such mental phenomena. To such relationship, in a word, as we may be enabled to recognize as subsisting between the objects in the world that surrounds us, and that constituent of our being which we are privileged to hope—that element of our existence which we are enjoined to believe—is destined to outlive (as a conscious principle) the *ultimate* dissolution of our material constitution—to survive (in the position of that which we designate "consciousness") the *final* disorganization of those organized structures which *here* constitute the *field* of its functions.

In relation to such considerations, it was my effort to make apparent how, as I conceive, the apparatus constructed for the fulfilment of the two following ends (ends, as I regard it, altogether *distinct* in their nature)—viz., 1st, of bringing surrounding objects into relation, or, as it were, into contact with the conscious principle of our being; and 2nd, of giving development to what are termed "mental phenomena;" how, I say, the apparatus provided for the fulfilment of these two ends, has been constructed of two distinct orders of organized structure, *each* of which has been placed in certain *relations* which are peculiarly its own; and *each* of which has to perform a function which is peculiar to itself.\*

I say "distinct orders of structure," inasmuch as the two tissues referred to differ, as I regard it, from each other in each of the two following particulars—viz., 1st, as regards the nature of their respective physiological *relations*; and 2nd, as regards the nature of the *phenomena* they are respectively designed to develop. For let us *contrast*, for a moment, the relations and functions, respectively of the two tissues before us—namely, of the "nerves of sensation" and of "cerebral matter." The one (viz.,

\* I have used the words "distinct orders" of organized structure (as above applied to nervous tissue and to cerebral matter) in preference to the expression "distinct classes" of structure; and that simply in consequence of my having already divided organized structures *generally* into two grand primary divisions or classes—namely, what I have ventured to term respectively "organizing agents," and "organized residual products." The reader will please to bear distinctly in mind that *each* of the two orders of structure referred to (viz., nervous tissue and cerebral matter), comprises under it a *variety* of sub-divisions of such structure; *all* of which belong to the same *order* of tissue, but each which sub-division *varies* in some respects from the other subdivisions of the same order. To such subdivisions may, for perspicuity, be applied the term "variety" or "species." Thus, for example, under the former of these two orders of structure (viz., nervous tissue), is comprised what have been termed the several "varieties" or the several "species" of nerves. Under "cerebral matter" are to be found the various subdivisions of that order of structure which give development to the several "varieties" or "species" of mental phenomena.

nerves of sensation), in consequence, observe, of the two following facts—viz., 1st, from its having been intimately associated, or, if I might so term it, *combined* with an unknown agency or principle, named “nervous influence or force;” and 2nd, from its having been placed in *direct* physiological relation or contact, observe, with the sensible objects in surrounding creation; the one, I say, of these two orders of organized structure, in consequence of its having so been *combined* and *related*, has been named by physiologists “nerves of sensation.” To the other of these two orders of organized structure, which has been, 1st, intimately associated, or, as it were, *combined* with the *conscious principle* of our being; and 2nd, placed in *direct* physiological relation or contact, observe (*not* like the nerves of sensation with the sensible objects in surrounding creation, but) with the *organized* structure just referred to—namely, with nerves; to the other, I say, of these two orders of organized structure which by Nature have so been *combined* and *related*, I have, in contradistinction to the former, or to nerves, applied the terms “cerebral matter.”

If, then, it be true that the two tissues before us (viz., nerves of sensation and cerebral matter) have in reality been respectively combined and related in the manner just stated, it is manifest that these tissues *differ* (that is, are distinct from each other), at least in the former of the two particulars referred to; that is, as regards the nature of their respective physiological *relations*. But I have further stated that they also differ from each other in another particular—namely, with regard to the nature of the phenomena they are respectively designed to develop. For what are the respective functions which these two orders of structure are called upon to discharge? They are, as I regard it, these—viz., the function of the former, that is, of the nerves of sensation, is, as I conceive, and as has been my effort to make apparent to the reader, to *stimulate* to the discharge of its physiological function that special subdivision of cerebral matter with which those “nerves of sensation” have been placed by Nature in direct physiological contact—namely, what has been termed the “seat of sensation.” The function of the latter—namely, of “cerebral matter,” is to give development to “mental phenomena.” If, then, it be true that these two statements be facts, it is manifest that the two structures before us *differ* or are distinct from each other in *each* of the two particulars referred to; and should such be the case, it would to me appear to be conducive to perspicuity and clearness to discriminate between them by some distinctive appellation.

Now, if the two orders of tissue referred to (viz., nerves of sensation and cerebral matter), in conjunction, constitute the apparatus constructed by Nature for the fulfilment of the two following ends—viz., 1st, of enabling the conscious principle of our being to receive the requisite impressions (viz., *stimuli* required for calling it to the discharge of its function) from the objects in surrounding creation; and 2nd, of giving development to what are termed “mental phenomena;” if, I say, it be true that such be the functions of this apparatus, I may perhaps be permitted for a moment (for the purpose, observe, of *contrasting* the nature of the mechanism of this apparatus with the nature of the mechanism of certain *other* apparatuses), I may, I say, for a moment be permitted to apply to the nerves of sensation and cerebral matter, conjointly, some such appellation as *the mental apparatus*.

If, then, for the purpose of *contrast*, the reader will for a moment permit such expression, let us contemplate this “mental apparatus” in relation to the *limits* or extent of its functions. Let us, in other words, consider it for a moment in reference to the following question—viz., *what or how much* could be effected by this apparatus *independently and alone*, that is, without the aid or superaddition of any *other* organized structure whatever? For an accurate acquaintance with the *limits* of the function of this apparatus—1st, *collectively* or as a whole; and 2nd, with regard to its *individual* component parts—would doubtless, as I conceive, simplify the reply to each of the two follow-

ing questions—viz., 1st, as to the nature of the relation in which *this* (viz., mental) apparatus may possibly stand towards any *other* apparatus (say, for example, a voluntary motor apparatus, a circulatory apparatus, or the like) with which such mental apparatus may be found upon further inquiry to have been placed in direct anatomic connexion; and 2nd (and it is *this* which I am now desirous of impressing upon the reader), it might suggest to us, as I conceive, the nature of the relation in which the individual component parts of some *other* apparatus (mark distinctly, some *other* apparatus), possibly *analogous* in the nature of its mechanism to the mental apparatus stand towards each other, should any *other* apparatus (*analogous* in its construction or mechanism to the mental apparatus) be found upon inquiry to exist in the constitution of man. I shall, for perspicuity, illustrate my meaning. An acquaintance with the nature of the relations of the several distinct component parts of the mental apparatus, might, I say, suggest to us the nature of the relation of the several distinct component parts—say of a voluntary motor apparatus, of a circulatory apparatus, or of *any* other apparatus whatever—provided distinctly it be found upon inquiry that such other apparatus had been constructed (with regard to its mechanism) upon principles *analogous* to those observed in the construction or mechanism of what, for perspicuity, I have termed the “mental apparatus.”

What, then, are the *limits* to the function of the nerves of sensation and of cerebral matter collectively regarded as an individual and independent apparatus?

Through the agency or instrumentality of the mental apparatus, independently and alone (if we be allowed, for a moment to suppose the possibility of its *existing* independently, that is, unconnected or unassociated with any *other* organized structure); through its agency or instrumentality, I say, independently and alone (provided it could be brought into *physiological relation*—1st, with sensible objects; and 2nd, with oxygen gas), we might be enabled, 1st, to feel, to see, to hear, to taste, and to smell; and we might further be enabled, 2nd, to will, to think, to judge, to reason, &c. Thus much, I say, we can, for the sake of argument, conceive, for a moment, the possibility of being effected by the nerves of sensation and by cerebral matter collectively, regarded as an individual and independent apparatus. But mark these two facts—1st, we should *not*, as the reader is already aware, be enabled to *move*; that is, we should not have the *ability* (however we might *will* so to do) to vary or change the position or locality of the apparatus referred to, so as to bring the conscious principle of our nature into relation with *other* objects in surrounding creation; and 2nd, when *once* that apparatus (viz., the various nerves of sensation and the several subdivisions of cerebral matter); when, I say, *once* that apparatus had given *full* development to these several phenomena referred to, its functions would be *for ever* at an end. I say, *for ever*, inasmuch as, after a *single* manifestation of the phenomena referred to, that apparatus, under the circumstances at present supposed, would be incompetent a *second* time to give development to its functions. For the development or manifestation of *vital* phenomena by *any* organized structure whatever is, as I have already endeavoured to make apparent to the reader, dependent upon and accompanied with the process of that structure's own *degeneration* or descent in the scale of organization; consequently, when *once* an organized structure or residual product (such as nervous tissue, cerebral matter, &c.) has *fully* developed its physiological functions, it would be *impossible* (unless such residual product should itself be *re-generated*) that the phenomena peculiar to that residual product could be *re-developed*, or, in other words, that such product could a *second* time give manifestation to its function. Consequently, if *motion* and *continuity of function* be required for the mental apparatus, it is obvious that Nature must have constructed distinct apparatuses adapted for fulfilling such requirements.

Now, that both *motion* and *continuity of function* are required for this mental apparatus, the reader is aware is

the fact; consequently, it has become necessary to place this apparatus in relation and contact with each of the two following distinct apparatuses or systems—viz., 1st, with a motor apparatus, which can be controlled in its operations by such mental apparatus; or, in other words, the action of which may be regulated by the conscious (viz., voluntary) principle of our being. In a word, with an apparatus constructed for the development of motion, whose functions may be regulated or controlled by that which we designate “will.” So that through the agency or instrumentality of such motor apparatus may be accomplished what are named “voluntary movements.”

And 2nd, this mental apparatus must have been placed in relation and contact with a circulatory apparatus (viz., a vascular system), through whose agency may be accomplished each of the two following essentially requisite ends—viz., 1st, of conveying to the mental apparatus its incidental stimulus (namely, oxygen gas), which we have already seen to be one of the requisites for the development of its functions; and 2nd, of conveying to that apparatus the materials for its re-generation or renewal, so as to admit of its functions being developed not merely once but a number of times—so as to admit, in a word, of continuity of function.

First, then, we are called upon to contemplate cerebral matter in its relation to voluntary movements. We are called upon, in other words, to consider the nature of the relation (and observe, more especially to contrast the nature of the mechanism) of the apparatus constructed for the development of mental phenomena and the altogether distinct and independent apparatus constructed for the development of muscular motion. Let us, then, inquire into the nature of the mechanism of this motor apparatus, and then contrast that mechanism with the mechanism of the mental apparatus. The voluntary motor apparatus has, as I regard it, been constructed by Nature upon identically one and the same general arrangement or plan (viz., with regard to its mechanism), as the mental apparatus which we have just been considering. In a word, these two apparatuses are, as I regard it, strictly analogous as to the nature of their mechanism or construction. Let me be distinctly understood: In this motor apparatus (in like manner as in the mental apparatus) we, in the first place, recognize two distinct orders of organized structure which stand towards each other; as I regard it, in an identically analogous relation to that in which stood the two orders of structure in the mental apparatus; and secondly, we find that these two orders of structure (in like manner as those comprised in the mental apparatus) differ from each other in each of the two following particulars—viz., 1st, as regards the nature of their respective physiological relations; and 2nd, as regards the nature of the phenomena they are respectively designed to develop. For what are the relations and functions of the structures respectively which constitute the voluntary motor apparatus? They are these: The one of its two orders of organized structure (which has received the name “voluntary nerves”),

has been placed in direct physiological relation and contact, observe, with the conscious (viz., voluntary) principle of our being; the other (which has received the name “muscular fibre”), has been placed in direct physiological relation and contact, observe (not with the conscious or voluntary principle of our being, but) with the organized structure just referred to—namely, with nerves. Consequently, it is obvious that these two orders of structures differ from each other in their physiological relations. And what are the functions of these structures respectively? The function of the former, or of voluntary nerves, is (in like manner as in the case of the nerves of the mental apparatus), to stimulate the latter (viz., muscular fibre) to the discharge of its physiological function; in a word, the function of such nerves is to cause that muscular fibre to contract. The function of the latter—viz., of muscular fibre, is like that of cerebral matter in the mental apparatus, to give development to an altogether distinct order of physiological phenomena—namely, the phenomena of muscular motion.

Let us inquire somewhat more minutely into the nature of voluntary movements; let us consider for a moment how such voluntary movements are effected. By what agency, then, are our voluntary movements accomplished? The reader is familiar with the reply to this question; he is aware that voluntary movements are accomplished by the contraction of what are called “voluntary muscles.” True; but how is the contraction of those muscles effected? How, that is, by what agency or means, are those voluntary muscles caused to contract? how, namely, through what instrumentality, is the quiescent condition of that organized structure disturbed, so as to admit of its developing the phenomena of muscular motion? What, in a word, is the specific stimulus of that organized residual product to the discharge of its specific physiological function? It is the influence shed upon such structure by nerves. It is that (whatever it be, or whatever its nature), which is developed or generated by what we term “voluntary nerves.” And how are those voluntary nerves called to the discharge of their function? how, that is, by what agency or instrumentality, are they caused to shed their nervous influence or force? What, in a word, is the specific stimulus of that organized residual product to the discharge of its specific physiological function? It is the conscious (viz., voluntary) principle of our being. That principle stands in the same relation to nerves of voluntary motion, as the sensible attributes of the objects in surrounding creation stand to the nerves of sensation; and the nerves of sensation stand, as I regard it, in the same relation to that special subdivision of cerebral matter (named “seat of sensation”) with which those nerves have been placed in direct anatomic connexion; as the nerves of voluntary motion stand to that organized residual product—viz., muscular fibre, with which they have been anatomically connected. In a word, the specific function of nervous tissue is, as I regard it, in both cases the following—namely, to stimulate to the discharge of its physiological function the organized structure (whatever it be) with which such nerves have been placed by Nature in direct anatomic connexion.

Hence (if it be true that the foregoing statements are facts) we perceive, in the first place, that as a system of nerves (viz., to develop and propagate “nervous influence or force”) has been placed by Nature intermediately between the objects in surrounding creation and that special subdivision of “cerebral matter” which those interposed nerves have been destined to stimulate to the discharge of its function; so, in like manner, a system of nerves (viz., to develop and propagate “nervous influence or force”) has been placed by Nature intermediately between the conscious (viz., voluntary) principle of our being and the muscular structure which those interposed nerves have been destined to stimulate to the discharge of its function. We perceive, in the second place, that as the former two disunited or separate objects (viz., cerebral matter and surrounding creation) are brought into relation, or as it were into contact, through the agency of an interposed system of

\* It might, perhaps, be desirable for me here to direct the reader's attention to the following consideration—viz., he will please to observe that with regard to organizing agents (that is, with regard to those organized structures which develop or generate what I have termed “organized residual products”), that with regard, I say, to organizing agents, the function of a circulatory apparatus is twofold—viz., of conveying to such agents—1st, their incidental stimulus in the form of oxygen gas; and 2nd, their specific stimulus in the form of what is termed “nutrient matter.” Whereas, with regard to organized residual products, the function of that circulatory apparatus, for the most part, is single—namely, that of conveying to such organized residual products their incidental (but not their specific) stimulus; the specific stimulus of such residual product being, for the most part, conveyed by a different channel. I say “for the most part,” inasmuch as I hope presently to make it apparent to the reader that such is not universally the case, but that the organized residual product, named “ganglionic nerves,” is supplied with both its stimuli (namely, specific as well as incidental) through the agency of the circulatory apparatus or vascular system.

nerves, to which has been given the name "nerves of sensation"; so, in like manner, the latter two disunited or separate objects (viz., our voluntary principle and our muscular structure) are brought into relation and contact, through the agency of an interposed system of nerves, to which has been given the name "nerves of voluntary motion." We perceive, in the third place, that as the "nerves of sensation" have been adapted by Nature for receiving from the sensible attributes of the objects in surrounding creation the peculiar species of stimuli which have been made specially requisite or essential to the normal discharge of their function; so, in like manner, "the nerves of volition" have been adapted by Nature for receiving from the conscious principle of our being the peculiar species of stimuli which has been made specially requisite or essential to the normal discharge of their function. We perceive, in the fourth place, that as "the nerves of sensation" have been placed with their recipient extremity (that is, with that part of their construction which has been specially adapted by Nature for receiving impressions from the objects that surround them); that as, I say, "the nerves of sensation" have been placed with their recipient extremity in direct physiological contact with the objects in surrounding creation which call them to the discharge of their function; so, in like manner, the "nerves of volition" have been placed with their recipient extremity in direct physiological contact with the conscious principle of our being which calls them to the discharge of their function; and finally, we perceive, in the fifth place, that as "the nerves of sensation" have been placed with their extremity of communication (that is, with that part of their construction which has been specially adapted by Nature for communicating—viz., to the seat of sensation—the stimulus of "nervous influence or force"); and, I say, we perceive, in the fifth place, that as "the nerves of sensation" have been placed with their extremity of communication in direct physiological contact with another and distinct order of organized structure, named "cerebral matter" upon which those "nerves of sensation" are destined to shed their "nervous influence or force," and thereby stimulate such cerebral matter to the discharge of its function; so, in like manner, the "nerves of volition" have been placed with their extremity of communication in direct physiological contact with another and distinct order of organized structure named "muscular fibre," upon which those "nerves of volition" are destined to shed their "nervous influence or force," and thereby stimulate such muscular fibre to the discharge of its function.

In a word, we perceive (if the foregoing be a correct statement of facts) 1st. that the sensible attributes of the object in surrounding creation stand in the same relation (viz., that of stimuli to action) to "the nerves of sensation" as the nerves of sensation stand to the seat of sensation; and 2nd. that the sensible attributes of the objects in surrounding creation stand to the nerves of sensation, and the nerves of sensation stand to the seat of sensation in the same relation (viz., that of stimuli to action) as "volition" stands to "the nerves of voluntary motion," and as the nerves of voluntary motion stand to muscular fibre.

Having now contemplated "the nerves of voluntary motion" in each of the two following relations—viz., 1st, with regard to their own specific stimulus; or in relation to that which calls them to the discharge of their function (namely, in their relation to the voluntary principle of our nature); and 2nd, with regard to the structure towards which they themselves act as specific stimulus; or in relation to that which they call to the discharge of its function (namely, in their relation to "muscular fibre"); having, I say, contemplated the "nerves of voluntary motion" in each of the two foregoing relations, it remains for us, in the third place, merely to inquire into the seat or locus of the ganglionic portion of that system of nerves. The ganglionic portion of the "nerves of voluntary motion" is seated within the pericranium. It is placed at the base of the cerebral hemispheres in the form of those ganglionic masses, to which have been given the name "corpora striata." It is unnecessary for the object at present in view to dwell further

in this place upon the consideration of this topic. I have now endeavoured to glance at, respectively, what I conceive to be the nature and relation of two distinct and separate systems of nerves—viz., what have been respectively named "nerves of sensation" and "nerves of voluntary motion." There is a third system of nerves in the constitution of man, with the anatomy and function of which the reader is doubtless already familiar, and to which he will at once perceive that all the foregoing observations strictly apply. I allude to that system of nerves which have been named the "true spinal nerves," and which gave development to what have been termed "reflex phenomena." To this third system of nerves (the reader being doubtless familiar with the researches of Dr. Hall, Mr. Grainger, &c.), it will be unnecessary for me at present to do more than merely refer, and that for the following purpose—namely, of applying to them the foregoing general observations (viz., as to the specific stimulus and specific physiological function) which it is my desire to make apparent are applicable to all systems of nerves universally. As regards the "true spinal nerves," we find the following to be facts—namely, 1st. the ganglionic portion (as the reader is aware) is situated in the interior, or at the centre of the spinal cord; 2nd. the recipient extremity of such nerves has been placed in direct physiological contact with that which has been specially provided by Nature for calling such nerves to the discharge of their function—namely, with the specific stimulus of such nerves (say, for example, alimentary matter during the act of deglutition); 3rd. the extremity of communication of such nerves has been placed in direct physiological contact with some other order of organized structure which such nerve is destined to stimulate to the discharge of its function; and finally, the specific physiological function of the "true spinal nerve" is to stimulate to the discharge of its physiological function (namely, by shedding thereon "nervous influence or force") some other order of organized structure which has been placed in direct physiological contact with the extremity of communication of those "true spinal nerves."

I have now made an attempt to place concisely before the reader what I conceive to be the nature and function of three distinct systems of nerves (the reader will please to bear distinctly in mind that the foregoing observations have had relation both to the nature and the function of three distinct and separate systems of nerves). My effort has been to convince him that the two following statements are facts—viz., 1st. that the function of each and of all of those three distinct systems of nerves is identically one, and the same in its physiological nature—namely, (as has been my desire to make apparent to the reader,) that of stimulating to the discharge of its physiological function some other order of tissue or organized structure (that is, distinct in its nature from nerves) with which each of those three distinct systems of nerves has been respectively placed by Nature in direct anatomic connexion. Such is the first consideration I have been desirous of impressing upon the reader; and 2nd. it has been my desire to convince him of this fact—namely, that the plan or arrangement adopted by Nature whereby shall be regulated (viz., as to activity and time) the performance or discharge of that function has been, for each and for all of these three distinct systems of nerves, identically one and the same in its physiological nature—namely, my desire has been to make it apparent to the reader, that each and all of those three distinct systems of nerves requires for the regulation of the discharge or performance of its function (viz., of shedding "nervous influence or force") the presence and operation

\* Under the terms "true spinal nerves," the reader will have the goodness to understand that I include (for perspicuity) those nerves whose ganglionic portion is seated, not exactly in what is called "the spine," but in that prolongation of the spinal cord, which has received the name "medulla oblongata," such as what are termed the "respiratory nerves," &c. I do so, inasmuch as it would be unnecessary for the purpose at present in view, to consider such nerves under a distinct and separate division, and not now need call

of some specific stimulus specially adapted by Nature to leading such system to develop its function. I do not attempt to convince the reader of the correctness of any of these statements, has been the object of my foregoing observations. But why, it may be asked, dwell thus long upon such considerations in connexion with the subject before us? Why occupy thus much of the reader's attention with the contemplation of the relation which subsists either between sensible objects, nerves of sensation, and cerebral matter; or between voluntary action, the nerves of volition, and the muscles of voluntary motion; or wherefore (in connexion with the present inquiry) engage in the consideration of the relations of the true spinal nerves? What can these considerations have to do with the pathology of inflammation and fever, or how can questions which appear to be altogether irrelevant have relation to the mechanism of the human circulatory apparatus? As such questions may very naturally suggest themselves to some of my readers, I shall explain why it is I have been induced to trespass thus long on their patience with the consideration of the foregoing inquiries. My motive has simply been this—namely, if the two foregoing statements be true with regard to three distinct, independent, and separate systems of nerves, should there then be found in the constitution of man a fourth system of nerves (of the relations and functions of which it had been supposed we are as yet altogether in ignorance), we should, as I regard it, be warranted *a priori* and independently of all experimental research, in anticipating the probability (to say the least) that the two following statements would, upon inquiry, be found to be facts—viz., 1st, that such fourth system of nerves would be found (like the other three systems) to have been placed in physiological relation and connect with some other order of tissue or organized structure (that is, distinct in its nature from nerves), which that fourth system of nerves was destined by Nature to stimulate to the discharge of its function; and 2nd, that this fourth system of nerves (like the other three systems) would be found to have been provided by Nature with some specific stimulus specially adapted for calling that system of nerves to the discharge of its function. So much, I say, I should be led to anticipate on the recognition of a fourth system of nerves, independently of a recognition of its physiological relations or anatomic connexion with any other order of organized structure. But should we, upon an anatomic examination of the constitution of man, not alone recognize the existence of a fourth system of nerves, but further find that such system has in reality (like the other three systems) been placed in direct anatomic connexion with some other order of tissue or organized structure (that is, distinct in its nature from nerves); should we, I say, find that such has been actually and in reality the arrangement adopted by Nature, then I should feel myself as it were irresistibly almost compelled to anticipate (1st) that the relation of these two orders of organized structure (viz., that fourth system of nerves, and the tissue with which it is found in anatomic connexion); that the relation, I say, of these two tissues would be found upon inquiry to be this—viz., that this fourth system of nerves had (like the other three systems) been anatomically united with the other tissue with which it is found in connexion for the following purpose—namely, of stimulating that other structure to the discharge of its function; and I should further feel warranted in anticipating—2nd, that this fourth system of nerves would be found (like the other three systems) to have been provided by Nature with some specific stimulus which could regulate (as to activity and time) the development or discharge of its function.

The reader will have the goodness (bearing the foregoing observations in mind) to reflect upon the two following facts—viz., 1st, a fourth system of nerves is found in the constitution of man, to which has been given the name, "the ganglionic" or "the sympathetic nerve;" and 2nd, that fourth system of nerves is found in direct anatomic connexion with another order of tissue or organized structure (that is, distinct in its nature from nerves), to which has been given the name "vascular tissue."

In order that the reader may be enabled the more readily to contrast the nature of the mechanism of the several distinct apparatuses referred to, and be thereby enabled, with greater facility, to recognize the bearing of these remarks, I shall now briefly recapitulate the foregoing observations, making (for the sake of greater perspicuity and clearness) some slight variation in the form of expression, as follows—viz.,

1st. We see, in the first place, that, what for a moment I have ventured to term "a mental apparatus," has been constructed, consisting of two orders of structure essentially distinct in their physiological nature—viz., 1st, "of cerebral matter," to give development to mental phenomena; and 2nd, of "a system of nerves," to stimulate such cerebral matter to the discharge of its function. We further see (in relation to this "mental apparatus") that its system of nerves has been supplied by Nature with a specific stimulus specially adapted for regulating (as to time and intensity) the development or discharge of its function; to which specific stimulus has been given the name "the sensible objects in surrounding creation."

2dly. We see, in the second place, that "a voluntary motor apparatus" has been constructed, consisting of two orders of structure essentially distinct in their physiological nature—viz., 1st, of "muscular fibre," to give development to motor phenomena; and 2nd, of "a system of nerves," to stimulate such muscular fibre to discharge of its function. We further see (in relation to this "voluntary motor apparatus") that its system of nerves has been supplied by Nature with a specific stimulus, specially adapted for regulating (as to time and intensity) the development or discharge of its function; to which specific stimulus has been given the name "volition."

3dly. We see, in the third place, that "an involuntary apparatus connected with the true spinal cord" has been constructed, consisting of two orders of structure essentially distinct in their physiological nature—viz., 1st, of the several structures with which the true spinal nerves are anatomically connected (such as sphincters, &c. &c.), which give development to the phenomena which appertains to such structures; and 2nd, of "a system of nerves," to stimulate such structures to the discharge of their functions. And we further see (in relation to this "involuntary apparatus connected with the true spinal cord") that its system of nerves has been supplied by Nature with a specific stimulus specially adapted for regulating (as to time and intensity) the development or discharge of its function.

4thly and finally. We see, in the fourth place, that "a circulatory apparatus" has been constructed, consisting of two orders of structure essentially distinct in their physiological nature—viz., 1st, of "vascular tissue," to give development to some species of phenomena; and 2nd, of "a system of nerves (viz., ganglionic)" which stands in some relation to such "vascular structure." From these facts, I feel warranted in deducing the two following conclusions—viz.,

1st. That the function of the system of nerves here referred to (viz., "the ganglionic nerves") is to stimulate to the discharge of its physiological function (whatever that

The reader will have the goodness to observe, that the two inferences or deductions which analogy would here lead us to anticipate in relation to what is termed "the ganglionic system of nerves," correspond exactly with the general inferences or deductions which I have already made an attempt to establish with regard to all systems of nerves—viz., 1st, that the specific physiological function of nervous tissue generally (whatever additional function, whether imaginary or real, may be attributed to its agency) is to stimulate to the discharge of its physiological function (by shedding thereon "nervous influence or force") those organized structures or residual products with which such nervous tissue has been placed by Nature in direct anatomic connexion; and 2nd, that nervous tissue (in common with all organized structure which develop "a vital phenomenon") requires for the normal discharge of its function the presence and operation of some specific stimulus.

be) the "vascular tissue" with which such nerves have been placed in direct anatomic connexion; and

2nd. That this system of nerves (in like manner as the other three systems) will be found to have been furnished by Nature with some specific stimulus specially adapted for regulating (as to time and intensity) the development or discharge of its function.

(To be continued.)

## CASE OF ACUTE GLANDERS DEVELOPED SPONTANEOUSLY IN A FEMALE.

By Dr. TESSIER.

On the 8th of June, 1852, a woman, named A. J., aged 47, was brought to the Hôtel Dieu at Lyons; she was married; worked in silk, and was only employed on black satins. Her lodging and food were healthy and sufficient. She had led a very sedentary life. From inquiries made with the greatest care of her and those about her, it appeared that she had not been in contact with horses, had had no transactions with coachmen, grooms, or cavalry soldiers, and had touched no object which could have been charged with the virus of glanders. There was a butcher's shop in her house, but not a slaughter-house; good meat alone was sold there.

In 1849, she had syphilis; a bubo appeared in the right groin, which suppurated and healed after two months. On May 30th, being exposed to a draught of air while her body was covered with sweat, she experienced a feeling of intense chill, which lasted four days, and was accompanied with debility, headache, anorexia, and pains in the joints. On the fourth day, when reaction was established, there appeared on the middle of the front of the right leg, a white pustule, surrounded by a red areola.

On the fifth day, the dorsal surface of each foot was covered with edematous erysipelas; and on the aspect of extension of the four limbs, there suddenly appeared tumours, with or without discolouration of the skin, consisting of more or less painful hard nodosities. On the succeeding days, the symptoms continued; an abscess formed under the pustule in the right leg, and was opened on the day before the admission of the patient into hospital.

On admission, her state was as follows: Countenance anxious; skin hot; pulse quick; tongue whitish and dry; she had headache, and general pain; much thirst; she answered questions with some difficulty. She was much agitated, and complained of not being able to sleep, or rather that her sleep was broken by painful startings. The legs were edematous, and presented diffused erythematous patches on their anterior part, and on the dorsal surface of the feet. She could not bear the least pressure on the great and second toes of the left foot. Eight or ten tumours, or nodosities, some tender with or without inflammation of the skin, others fluctuating, and evidently formed by abscesses, existed on both upper and lower limbs. A sanious pus escaped from the abscess in the leg; two pustules resembling ecchyma were observed, one on the styloid process of the right tibia, and the other on the summit of an abscess on the thigh. She was ordered to have diaphoretic tisane, a calomel mixture, ointment, and a poultice to the abscess.

Up to June 14th, the symptoms went on increasing, and she was ordered to take tincture of iodine, and to have the sores dressed with powder of cinchona and charcoal. Under this treatment, gangrene of the leg, which had set in, was arrested. At this time, there appeared two new pustules like those of variola at the stage of suppuration, and an abscess with violet coloured skin, over the left malar bone. Up to this time, Dr. Tessier had treated the case as one of fever, with the tendency to the formation of abscesses and to erysipelas; but the appearance of the varioloid pustules on the face, led him to suspect that the case had some re-

semblance to one of glanders. As, however, there was as yet no purulent discharge from the nostrils, he did not arrive at any conclusion.

On June 16th and 17th, the varioloid pustules increased in number. The face expressed stupor, the tongue was dry, the abdomen was in a state of meteorismus. M. Lecoq, director of the Veterinary School, examined the patient, but could not decide whether she had glanders. The abscesses and pustules increased in number; there was extreme prostration, with subsultus tendinum, and some petechiae on the thorax.

On June 20th, there appeared erysipelas on the face, below the internal angle of the eyebrows; it spread rapidly, and on the next day assumed a blackish tint, and became covered with phlyctenae. The pustules and abscesses became more and more numerous; the pulse was 130; the tongue appeared as if roasted, and some small blackish crusts were observed in the interior of the nares, but there was no discharge.

On June 21st, diarrhoea set in, and phlyctenae appeared on some of the abscesses on the limbs, and the patient died in the morning of the 22nd.

*Post-mortem examination twenty-four hours after death.*  
*Exterior.* There were six or seven bullae on the limbs containing a sero-purulent liquid, and two gangrenous phlyctenae, one at the root of the nose, the other on an abscess in the thigh. There were twenty-nine opaque pustules, resembling those of small-pox, at the period of suppuration, but without the central depression. Traces of erysipelas were only seen in the face. Where it had been present on the feet and hands, thick pus was found beneath the skin. There were twenty-seven abscesses, two of which were gangrenous. Some were subcutaneous; others were deeper seated among the muscles; while some were within the joints. Pus was found in both knees and elbows, and in some of the joints of the toes. The pus was generally thick, unhealthy, and mixed with grumous clots. In some of the abscesses, it was sanious.

*Interior.* The brain was healthy; there was slight arborescent injection of the arachnoid. The sinuses of the dura mater were filled with dark blood. In the nasal fossae, the mucous membrane was thick, softened, of a very deep red, and was easily detached from the bones. It was infiltrated with a sanguinolent serosity through nearly its whole extent. At some points, it presented granular enlargements infiltrated with pus (an essential character of glanders). The turbinate bones were of a blackish aspect; they were filled with sanguinolent and purulent mucosity; so that, if the patient had lived, two or three days longer, there would have been a discharge from the nostrils. The mucous membrane of the fauces presented the same appearance as the pituitary membrane, but in a less degree. There was no abscess in the lungs; but they were infiltrated with dark blood, and the left lung presented, especially posteriorly, marked lobular engorgement. The heart was healthy; as were also the liver, spleen, pancreas, and kidneys. The sexual organs presented no trace of syphilis, and the stomach, there was an ecchymotic patch of the sized of a franc piece, and the mucous membrane here was softened. Throughout the intestines, there were only some red arborescent patches of cadaveric injection. Peyer's and Brunner's glands were healthy. The absence of pathological changes in the intestines is one of the most important points in the anatomical history of glanders; the lymphatic glands were not visibly engorged.

On seeing these appearances, M. Lecoq, of the Veterinary School, who was present, did not hesitate to affirm that, if he saw similar appearances in a horse, he should consider the case one of acute glanders. One proof, however, was required—that of inoculation. Some pus, taken during life from an abscess, was introduced into a lean but healthy horse; and in ten days the horse died of all the symptoms of acute glanders. On post-mortem examination, the characteristic appearances were found on the pituitary membrane.—*Lond. Jour. of Med.*

## OBSERVATIONS UPON A GENERAL METHOD FOR DETECTING ORGANIC ALKALOIDS IN CASES OF POISONING.

By Professor STAS of Brussels.

WHATEVER certain authors may have said on the subject, it is possible to discover in a suspected liquid all the alkaloids, in whatever state they may be. I am quite convinced that every chemist who has kept up his knowledge as to analysis, will not only succeed in detecting their presence, but even in determining the nature of that which he has discovered, provided that the alkaloid in question is one of that class of bodies, the properties of which have been suitably studied. Thus he will be able to discover conia, nicotine, aniline, picoline, petinine, morphine, codeine, narcotine, strychnine, brucine, veratrine, colchicine, delphine, emetine, solanine, aconitine, atropine, and hyoscyamine. I do not pretend to say that the chemical study of all these alkaloids has been sufficiently well made to enable the experimenter who detects one of them to know it immediately, and affirm that it is such an alkaloid, and not such another. Nevertheless, in those even which he cannot positively determine or specify, he may be able to say that it belongs to such a family of vegetables—the Solanaceæ, for example. In a case of poisoning by such agents, even this will be of much importance. The method which I now propose for detecting the alkaloids in suspected matters, is nearly the same as that employed for extracting those bodies from the vegetables which contain them. The only difference consists in the manner of setting them free, and of presenting them to the action of solvents. We know that the alkaloids form acid salts, which are equally soluble in water and alcohol; we know also that a solution of these acid salts can be decomposed so that the base set at liberty remains either momentarily or permanently in solution in the liquid. *I have observed that all the solid and fixed alkaloids above enumerated, when maintained in a free state and in solution in a liquid, can be taken up by ether when this solvent is in sufficient quantity.* Thus, to extract an alkaloid from a suspected substance, the only problem to resolve consists in separating, by the aid of simple means, the foreign matters, and then to find a base which, in rendering the alkaloid free, retains it in solution, in order that the ether may extract it from the liquid. Successive treatment by water and alcohol of different degrees of concentration, suffices for separating the foreign matters, and obtaining in a small bulk a solution in which the alkaloid can be found. The bicarbonates of potash or soda, or these alkalies in a caustic state, are convenient bases for setting the alkaloids at liberty, at the same time keeping them wholly in solution, especially if the alkaloids have been combined with an excess of tartaric or of oxalic acid.

To separate foreign substances, animal or otherwise, from the suspected matters, recourse is commonly had to the tribasic acetate of lead, and precipitating the lead afterwards by a current of sulphuretted hydrogen. As I have several times witnessed, this procedure has many and very serious inconveniences. In the first place, the tribasic acetate of lead, even when used in large excess, comes far short of precipitating all the foreign matters; secondly, the sulphuretted hydrogen, which is used to precipitate the lead, remains in combination with certain organic matters which undergo great changes by the action of the air and of even a moderate heat; so that animal liquids which have been precipitated by the tribasic acetate of lead, and from which the lead has been separated afterwards by hydrosulphuric acid, colour rapidly on exposure to the air, and exhale at the same time a putrid odour, which adheres firmly to the matters which we extract afterwards from these liquids. The use of a salt of lead presents another inconvenience—viz., the introduction of foreign metals into the suspected matters, so that that portion of the suspected substance is rendered unfit for testing for mineral substances. The successive and combined use of water and alcohol at different states of concentration, permits us to search for mineral substances, whatever be their nature,

so that in this way nothing is compromised, which is of immense advantage when the analyst does not know what poison he is to look for.

It is hardly necessary to say, that in medico-legal researches for the alkaloids, we ought never use animal charcoal for decolourizing the liquids, because we may lose all the alkaloid in the suspected matters. It is generally known that animal charcoal absorbs these substances at the same time that it fixes the colouring and odiferous matters.

The above observations do not proceed from speculative ideas only, but are the result of a long series of experiments which I have several times employed for discovering these organic alkaloids. To put in practice the principles which I have thus explained, the following is the method which I propose to set about such an analysis;—I suppose that we wish to look for an alkaloid in the stomach or intestines; we commence by adding to these matters twice their weight of pure and very strong alcohol;\* we add afterwards, according to the quantity and nature of the suspected matter, from ten to thirty grains of tartaric or oxalic acid—in preference tartaric; we introduce the mixture into a flask, and heat it to 160 or 170 deg. F. After it has completely cooled it is to be filtered, the insoluble residue washed with strong alcohol, and the filtered liquid evaporated in vacuo. If the operator has not an air-pump, the liquid is to be exposed to a strong current of air at a temperature of not more than 90 deg. F. If, after the volatilization of the alcohol, the residue contains fatty or other insoluble matters, the liquid is to be filtered a second time, and then the filtrate and washings of the filter evaporated in the air-pump till nearly dry. If we have no air-pump, it is to be placed under a bell-jar over a vessel containing concentrated sulphuric acid. We are then to treat the residue with cold anhydrous alcohol, taking care to exhaust the substance thoroughly; we evaporate the alcohol in the open air at the ordinary temperature, or still better, in vacuo; we now dissolve the acid residue in the smallest possible quantity of water, and introduce the solution into a small test-tube, and add little by little pure powdered bicarbonate of soda or potash, till a fresh quantity produces no further effervescence of carbonic acid. We then agitate the whole with four or five times its bulk of pure ether, and leave it to settle. When the ether swimming on the top is perfectly clear, then decant some of it into a capsule, and leave it in a very dry place to spontaneous evaporation.

Now, two orders of things may present themselves; either the alkaloid contained in the suspected matter is liquid and volatile, or solid and fixed. I shall now consider these two hypotheses.

*Examination for a Liquid and Volatile Alkali.*

We suppose there exists a liquid and volatile alkaloid. In such a case, by the evaporation of the ether, there remains in the inside of the capsule some small liquid stræ which fall to the bottom of the vessel. In this case, under the influence of the heat of the hand, the contents of the capsule exhale an odour more or less disagreeable, which becomes, according to the nature of the alkaloid, more or less pungent, suffocating, irritant; it presents, in short, a smell like that of a volatile alkali masked by an animal odour. If we discover any traces of the presence of a volatile alkaloid, we add then to the contents of the vessel, from which we have decanted a small quantity of ether, one or two fluid drachms of a strong solution of caustic potash or soda, and agitate the mixture. After a sufficient time, we draw off the ether into a test-tube; we exhaust the mixture by two or three treatments with ether, and unite all the ethereal fluids. We pour afterwards into this ether, holding the alkaloid in solution, one or two drachms

\* When we wish to look for an alkaloid in the tissue of an organ, as the liver, heart, or lungs, we must first divide the organ into very small fragments, moisten the mass with pure strong alcohol, then express strongly, and by further treatment with alcohol exhaust the tissue of everything soluble. The liquid so obtained, is to be treated in the same way as a mixture of suspected matter and alcohol.

of water, acidulated with a fifth part of its weight of pure sulphuric acid, agitate it for some time, leave it to settle, pour off the ether swimming on the top, and wash the acid liquid at the bottom with a new quantity of ether. As the sulphates of ammonia, of nicotine, aniline, quinine, procaine, and pectine, are entirely insoluble in ether, the water acidulated with sulphuric acid, containing the alkaloid in a small bulk, and in the state of a pure sulphate, but as the sulphate of quina is soluble in ether, the ether may contain a small quantity of this alkali, but the greater part remains in the acidulated watery solution. The ether, on the other hand, retains all the animal matters which it has taken from the alkaline solutions. If it on spontaneous evaporation leaves a small quantity of a feebly-coloured yellowish residuum of a repulsive animal odour, mixed with a certain quantity of sulphate of quina, this alkaloid exists in the suspected matter under analysis. To extract the alkaloid from the solution of the acid sulphate, we add to the latter an aqueous and concentrated solution of potash, of caustic soda, or of lime, and exhaust the mixture with pure ether; the ether dissolves ammonia, and the alkaloid is now free. We expose the ethereal solution at the lowest possible temperature to spontaneous evaporation; almost all the ammonia volatilises with the ether, whilst the alkaloid remains as residue. To eliminate the last traces of ammonia, we place for a few minutes the vessel containing the alkaloid in a vacuum over sulphuric acid, and obtain the organic alkaloid with the chemical and physical characters which belong to it, and which it is now the chemist's duty to determine positively.

I applied, on the 3rd March, 1851, the process which I have described, to the detection of nicotine in the blood from the heart of a dog poisoned by the carbide of ammonia (C<sub>2</sub>H<sub>3</sub>N). I introduced into the trachea, and I was able in a most positive manner to determine nicotine in the blood. I was able to determine its physical characters, its odour, taste, and alkalinity. I succeeded in obtaining the chloro-platinate of the base perfectly crystallized in quadrilateral rhomboidal prisms of a rather dark yellow colour, and to ascertain their insolubility in alcohol and ether. I have applied the same process for the detection of opium in a very old tincture of henbane, which my friend and colleague Mr. de Lemprière was so kind as to put at my disposal; and I was equally successful in extracting from the liquid colourless resin, presenting all the physical and chemical properties of this alkali. I was also able to prove that the alcohol which bores down in solution, carries off a notable portion of this alkaloid when the solvent is exposed to spontaneous evaporation.

*Examination for a Solid Alkaloid.*—I suppose that this alkaloid is solid and fixed, in that it does not depend on the nature of the alkali, but on the nature of the substance from which it is extracted. The acid solution to which we have introduced the carbonate of soda, may leave or not quinine, containing an alkaloid. If it does, we add a solution of caustic potash or soda, and the liquid is agitated briskly with ether. This dissolves the vegetable matter, and the alkaloid remains in the solution of potash or soda. In either case, we exhaust the matter with ether. Whatever be the agent which has set the alkaloid free, whether it be the bicarbonate of soda, or potash, or caustic soda, or potash, it remains, by the evaporation of the ether, on the sides of the capsule as a solid body, but more commonly a colourless milky liquid, holding solid matters in suspension. The colour is animal, disagreeable, but not pungent. It turns litmus paper permanently blue.

When we thus discover a solid alkaloid, the first thing to do is to try and obtain it in a crystalline state, so as to be able to determine its form. Put some drops of alcohol in the capsule which contains the alkaloid, and leave the solution to spontaneous evaporation. It is, however, very rare that the alkaloid obtained by the above process is pure enough to crystallize. Almost always it is soiled by foreign matters. To isolate these substances, some drops of water, feebly acidulated with sulphuric acid, are poured

into the capsule, and then moved over its surface, so as to bring it in contact with the matter in the capsule. Generally we observe that the acid water does not moisten the sides of the vessel. The matter which is contained in it separates into two parts, one formed of greasy matter which remains adherent to the sides, the other, alkaline, which dissolves and forms an acid sulphate. We cautiously decant the acid liquid, which ought to be limpid and colourless, if the process has been well executed; the capsule is well washed with some drops of acidulated water, added to the first liquid, and the whole is evaporated to three-fourths in vacuo, or under a bell-jar over sulphuric acid. We put into the residue a very concentrated solution of pure carbonate of potash, and treat the whole liquid with absolute alcohol. This dissolves the alkaloid, while it leaves untouched the sulphate of potash and excess of carbonate of potash. The evaporation of the alcoholic solution gives us the alkaloid in crystals.

It is now the chemist's business to determine its properties, to be able to prove its individuality. I have applied the principles which I have just expounded to the detection of morphine, iodine, strychnine, brucine, veratrine, emetine, colchicine, aconitine, atropine, hyoscyamine, and I have succeeded in isolating without the least difficulty these different alkalies, previously mixed with foreign matters.

I have thus been able to extract, by this process, morphine from opium, strychnine and brucine from nuxvomica, veratrine from extract of veratrum, emetine from extract of ipecacuanha, colchicine from tincture of colchicum, aconitine from an aqueous extract of aconite, hyoscyamine from a very old extract of henbane, and atropine from an equally old tincture of belladonna. Thus it is in all evidence that such this process to the consideration of chemists who undertake medico-legal researches.—*Bulletin de l'Académie Royale de Médecine de Belgique, and Edin. Monthly Jour.*

## FRACTURE OF THE FEMUR NON-UNION— DEATH. CANCER OF THE LUNGS, AND CANCEROUS DEGENERATION OF THE EXTREMITIES OF THE FRAGMENTS.

Miss E. S., fifteen years of age, with no hereditary predisposition to disease, apparently in the enjoyment of substantial health, highly educated, and of a nervous temperament, has had, for upwards of two years, a small tumour of the size of a walnut, on the inner aspect of the thigh, directly over the femoral artery. It has never caused her any inconvenience, is painless, and the lymphatic glands of this region have no appearance of being diseased. In December, 1850, while descending a staircase, and in making the last step, the thigh bone of the right side gave way, and she fell helpless to the floor. The fracture was at the junction of the middle and lower thirds. During the first eight days she had an attack of measles, but nothing occurred worthy of note. The fracture was treated in the straight position, and at the end of the fifth week the bone seemed united. During this time, however, the tumour of the thigh increased in size and ulcerated; the nervous system became involved, and her extreme irritability had frequently to be controlled with chloroform, and finally, upon starting from her sleep, the thigh was refractured in the former situation. The general system now sympathized more acutely; emaciation followed; the pulse became rapid, severe neuralgia constantly harassed her, and at length, about five months after the first accident, death put an end to her sufferings.

*Autopsy.*—Great emaciation: tumour, a large encephaloid growth in the second stage. Lungs both filled with cancerous masses, varying from the size of a shot to that of a walnut. In the thigh the callus had been removed, and an irregular encephaloid mass occupied its place; cancerous matter was also found deposited in the lower part of the shaft of the femur, and about the knee-joint; it was detected in no other part of the body.—*N. Y. Journal.*

## CASE OF SUPPOSED POISONING BY BATTLE'S SOLUTION OF OPIUM, INJECTED INTO THE RECTUM.

On 18th September, an inquest was held by Mr. Wakley, on the body of the Hon. Major Charles R. W. Forester, aged 41, who had died at 6, Cavendish-square, early on the morning of Thursday, the 16th, after using an opiate enema, prescribed by Mr. Richard Dawson, of 15, Finsbury Circus. Mr. Clarkson appeared on behalf of Mr. Dawson. The inquiry was not completed, and the inquest was adjourned to the 28th, but from the evidence and what transpired in the room, we learned that the deceased gentleman had for several months been undergoing hydropathic treatment; that he had afterwards put himself under the care of a homoeopathic practitioner; and latterly, conceiving himself to be affected with *spermatorrhœa*, had applied for assistance to Mr. or Dr. Dawson, author of a work on that disease, and, as our readers may remember, the subject of encomiums in a pamphlet extensively distributed some years ago by a certain disinterested Mr. Teevan, the victim of a set of unscrupulous quacks, whom he denounces, all to the manifest advantage of Mr. Dawson. It appeared that on the morning preceding his death, after eating a hearty breakfast and being in his usual health, Major Forester paid a visit to Mr. Dawson, and when he returned about two hours afterwards he complained of suffering acute pain, the result of an operation he had undergone. He had to be assisted to his bed-room, had a warm hip-bath, and at two p.m., sent to Messrs. Savory of Bond-street, with a verbal message, requesting them to send thirty grains of Dover's powder, a syringe, and an enema, to be composed according to the following prescription of Mr. Dawson:—

R. Liquor opii. sedativ. ʒij.  
Tinct. opii. camphor ʒss.  
Mucil. ʒij.  
Spir. camph. mxx.  
Ft. enema.

Mr. Savory refused to supply the Dover's powder without a written order, but sent the enema prescribed, with a gum-bottle. In less than two hours a written order for fifteen grains of Dover's powder was received; with a request that a fresh supply of the enema, with a different instrument, should be sent, as the patient had failed in using the gum-bottle. In delivering the fifteen grains of Dover's powder, Mr. Savory cautioned the servant by telling him that the paper contained what was equal to three doses; he also gave him another bottle of the enema and a pewter syringe. The evidence of the wife of the deceased not having been taken, it did not come out clearly at what time part of the Dover's powder was taken, or when the second supply of the injection was used. It was stated by the valet that about eight his master had tea and partook of a mullin, and that a little before nine he was summoned to remove a basin which he supposed to have been used in throwing up the injection. In the bottom of the basin he observed a little of the enema; there was also a small quantity of it in the syringe, and a little had been spilled on the carpet. The servant did not see the deceased after this till eleven o'clock, when he appeared in his ordinary health. He told the servant that they would not have prayers, and that he might go to bed. In less than ten minutes afterwards the bell rang with violence, and the valet was ordered by the deceased's wife to bring immediately the first medical gentleman to be found in the neighbourhood.

Dr. Halley of Queen Anne-street, reached the house within a few minutes. He found the patient reclining on the sofa, in a profuse perspiration, his eyes closed, breathing tranquil, his countenance pale, and of a slightly leaden hue; when loudly spoken to and shaken, he became partially conscious, but he never spoke; the pupils were in a middle state between dilatation and contraction, and contracted under the influence of a strong light. Dr. Halley was informed that the gentleman had undergone an operation in the forenoon, and the paper

containing the Dover's powder was shown, with only a part, estimated to be eight grains, removed from it; Dr. Halley kept bathing the temples and forehead with cold water for above an hour, and gave him brandy and ammonia; the patient gradually became more conscious, but did not speak in reply to questions. Before leaving, Dr. Halley strongly urged the importance of his being instantly sent for, should the sleep become more deep, or any new symptom present itself; and on his reaching home, he put out his stomach-pump with other things, in readiness, in case he should be called. It was not till four hours afterwards—viz., at half-past four, that he was summoned, and on hastily repairing to the house, he found the patient dead. The stomach-pump was used, but no smell of opium was detected in what came away; and there were no signs of returning animation. Dr. Halley was now shown, for the first time, the prescription, above copied, for the enema, and he also found a six-drachm phial, which contained half of the quantity of the injection that had been prescribed, and these he took possession of. The melancholy occurrence having been notified to the coroner, an order was given for a post-mortem examination, and Mr. Shaw, Surgeon to the Middlesex Hospital, was requested to assist Dr. Halley. It may be shortly stated, that throughout the whole body, every organ of which was carefully examined, no morbid lesion was found, except in the urethral orifice of the bladder, where a circular portion of the mucous membrane, the third of an inch in diameter, was converted into a thin dead film or superficial eschar, exactly like the effect of a touch of lunar caustic; a congeries of small bloodvessels concentrated round this eschar; the mucous membrane of the trigone was highly vascular, and the same membrane in the bladder generally, was marked with patches of vascular spots; but all the above appearances were manifestly of recent origin, and were presumed to be the consequences of the operation alleged to have been performed on the patient on Wednesday forenoon; the prostate vesiculæ seminales and urethra were quite sound. The rectum was contracted, the mucous membrane healthy, and in the small quantity of feces which remained there was no smell of opium. The only abnormal changes met with in the other organs, were from congestion of the blood, which was fluid throughout, except in the inferior vena cava, and in both ventricles of the heart, where small, soft, imperfectly coagulated clots were found; both lungs were much gorged with blood, particularly in their inferior lobes and posteriorly; the brain was but moderately congested; the mucous membrane of the stomach was healthy.

The chief cause of the adjournment of the inquest was said to be the doubt entertained by the coroner, whether so small a quantity of opium as was proved by the evidence to have been taken by the patient could produce death, and instructions were given for a chemical examination to be made. According to the facts stated, it appeared that the deceased gentleman had swallowed eight grains of Dover's powder; it moreover appeared, that in injecting the enema, only half of the quantity prescribed had been taken from the bottle, and that of that half, he spilled some on the carpet and into the basin, and some was retained in the syringe. It therefore did not seem probable that more than half a drachm, if so much, of the Battle's solution of opium prescribed in this enema was received into the rectum. Before the question can be satisfactorily answered whether such a quantity of opium so administered, partly by the mouth and by the rectum, can produce death (for the mode of death, as well as the post-mortem appearances, corresponded with those of fatal narcotism from opium), two points have to be attended to: one that belongs more particularly to the province of the medical man—viz., does opium injected into the rectum produce its narcotic effects more powerfully than if taken into the stomach? A great surgeon, Baron Dupuytren, has stated his opinion that such is the case; and the other point, relating more particularly to the objects of this journal is, "What is the true strength of Battle's solution of opium?" When that question was put at the in-

quest to Mr. Savory's assistant, who dispensed the injection, he answered, without hesitation, that it was of the same strength as *tinctura opii*, and the answer was received without any observation or objection. Now there are some writers, referred to in Dr. Taylor's work upon Poisons, who consider the *liquor opii sedativus* to be three times as strong as *tinctura opii*. Dr. Christison describes it as one-third stronger than the tincture. Is it creditable that such doubts should exist about the strength of a preparation so generally prescribed by our most eminent practitioners?—*Pharm. Jour.*

#### REVIEWS AND NOTICES OF BOOKS.

**THE NATURE, SYMPTOMS, AND TREATMENT OF CONSUMPTION**, being the Essay to which was awarded the Fothergill Gold Medal by the Medical Society of London. By R. P. Cotton, M.D., Assistant-Physician to the Hospital for Consumption, London. 1852. 8vo. pp. 288.

This treatise has not been published (the author tells us) with the object of introducing "any newly-discovered cure for consumption, or to advance any speculative theory as to the origin of tubercular diseases; but to present a practical exposition of phthisis, derived from personal observation."

Dr. Cotton arranges his subject under three heads; the "nature of consumption" is first considered; next its "symptoms;" and lastly, "its treatment." The topics which come under the first of these heads are, "distinction between phthisis and tubercle; consumption a non-contagious disease, mode of origin; general characters and minute structure of tubercle; situation of tubercle; curability of consumption; identity of consumption and scrofula; relation of consumption to other tubercular diseases, and to diseases of a different character; predisposing and exciting causes."

Dr. Cotton does not believe in the contagiousness of phthisis. "Experience might, at first sight, he says, appear to favour the idea of phthisis being a contagious disease, as examples are sufficiently common of persons previously in robust health having succumbed to its attacks, after the painful trial of tending a consumptive husband, or wife, or sister, or friend. But when it is remembered, that whatever lowers the physical powers, and depresses the spirits—more especially if associated with a morbid mental impression so likely in such cases to prevail—is in itself sufficient to engender phthisis, we have a satisfactory explanation of these occurrences, and might even wonder that they are not more common."

The particular tissue in which tubercle is formed, or first deposited, has been a disputed point; it might be anticipated (the author observes) that anything separated from the blood—which permeates every where—would not be limited to any one structure. The tubercular deposit is accordingly found both upon free surfaces and within the pulmonary texture. When slowly deposited, it has a manifest tendency to accumulate in the areolar tissue between the air-cells; but even under such circumstances it is far from being limited to this part, but may be found also both in the interior of the air-cells and in the smaller bronchial tubes. "I have seen it (Dr. Cotton says) in all these situations, both in uninjected and injected specimens, and I have reason to believe that it sometimes occurs within the coats of the bloodvessels themselves."

The question as to the inflammatory or non-inflammatory origin of tubercle has been often debated; the author believes that tubercular matter is formed in two ways—1, "by a gradual and uninfammatory process of separation from the blood; 2, by inflammatory action ending in a morbid serofulous secretion, instead of a healthy or fibrinous one. The first of these is by far the most common—in fact, the ordinary mode of its production, and may be illustrated by any of the numerous cases where phthisis begins slowly, and advances insidiously, unattended at its commencement by any marked thoracic symptoms; the second is comparatively

rare, and is to be seen in those cases where pneumonia, pleuro-pneumonia, or bronchitis, either from neglect or a consumptive predisposition, become obstinate and chronic, and finally pass into confirmed phthisis."

In the chapter upon the curability of phthisis, the author discusses the question as to its curability in the several stages. In its first stage, the tubercular deposit (Dr. Cotton observes) "may, under favourable circumstances, become absorbed, and the health be perfectly restored; or the tubercle may remain latent and unproductive of any serious inconvenience for a very considerable time—perhaps even during a long life—the patient being able, under proper care, and by the exercise of discretion, to enter with so much freedom into the duties even of an active life, that were it not for the chance of some depressing cause subsequently reviving the disease, a cure might be said to have been effected."

In the second stage, Dr. Cotton has seen a few cases, in which, after the most unequivocal evidence of tubercular softening, all the active symptoms of pulmonary disease completely disappeared, and the general health was so far restored that the patients seemed to have recovered. But it must be confessed, he adds, "such examples are rare, and the most successful treatment of the second stage of phthisis seldom proceeds beyond an arrest of the tubercular symptoms, and a partial and temporary restoration of health." "I have seen, he says, this painfully illustrated on many occasions, where, after every urgent symptom had long been absent, and the most hopeful anticipations appeared to have been realized, the patient has suddenly relapsed, and all the phthisical symptoms have reappeared."

In the third stage, "although I would not deny (Dr. Cotton says) the possibility of a cure, by the escape of the softened tubercle, and the healing of the cavity, I cannot help maintaining its extreme rarity, and confessing that I have never met with an unequivocal example of its occurrence." "It is, happily, not very unfrequent (he observes) to find persons even in the third stage of consumption with their pulmonary disease so stationary, and their general health so greatly restored, as to be able, by the exercise of proper care, to pursue their former avocations, and to enjoy for a long time—perhaps for some years—a fair amount of happiness. But such persons cannot be strictly said to be cured of their disease; upon close investigation, the most fortunate of them will be found to be more or less invalids, and sooner or later, they will fall the victims of phthisis; their pulmonary cavities, although perhaps considerably contracted and quiescent, have not healed, but are liable at any time to become the seat of renewed disease; whilst some neighbouring tubercle is almost certainly present, ready to develop, under any exciting cause, its fatal properties."

The second part, which is devoted to the symptoms of phthisis, commences with a general description of its several stages, followed by "a more particular description of the prominent symptoms." The "different forms of phthisis" are next described, and "the physical signs" conclude this part.

In the third part, Dr. Cotton considers, first, "preventive treatment," next the treatment "before tubercle is deposited," "after tubercle has been deposited," and the "treatment of the various forms of consumption." The volume concludes with a "more particular description of the chief agents employed in treatment." Under the latter head, Dr. Cotton mentions the results of some experiments made by him with various oils, in order to discover a substitute for cod-liver oil. "With a view of ascertaining the value of substances bearing more or less analogy to cod-liver oil, I have made repeated trials (he observes) of train oil, the oil of the spermaceti whale, and neat's-foot oil, as well as of linseed, almond, and olive oils."

"The common train oil, after being disguised by some aromatic essence, such as cinnamon or peppermint, in order

that the patient's imagination might have no share in the result, was given in fifty cases, in different stages, and notes were carefully preserved. Except in ten instances, it was not continued longer than a month; for within this period its inferiority to cod-liver oil became too manifest to justify further experiment. In these ten cases it was taken, and for a considerable time, with good effect, especially in those which had reached the third stage; there was in each an increase in weight; the cough was lessened; some of the most urgent symptoms were relieved, and the health improved. Upon the whole, however, the benefit appeared less than might have been expected from cod-liver oil.

The *spermaceæ* oil was tried in the same number of cases, but with less satisfactory results. In four or five instances the health improved, the weight slightly augmented, and the cough diminished; but in none was the advantage of this remedy either so conspicuous or long continued as that of even the train oil; and upon the whole, the effect was so little encouraging as to lead to its early discontinuance.

*Nearly-foot oil* was given to twenty patients, and persevered with for a longer period than either of the preceding, but with a result of a very similar kind. Some gained slightly in weight, and expressed themselves as having received benefit, but the majority appeared so little, if at all, improved by its employment, that this oil, like the others, ultimately gave place to its more trustworthy competitor.

From these observations it may, I think, be concluded that other animal oils possess the same qualities as those of cod-liver oil, although in a less degree; and that the nearest approach to the latter is found in the common whale or train oil, which, in case of necessity, might to some extent become its substitute. It may be thought that the trial afforded them was of insufficient duration; but I became so soon convinced of their comparative inferiority, as to feel it would be wrong to sacrifice to further experiment the most fitting opportunity for making some impression upon the course of the tubercular disease.

The oils of *linseed*, *almond*, and *olive*, may be included under one head. They were given respectively in about thirty cases, in all of which there was either no improvement whatever, or it was so slight as to render it difficult to determine whether or not the oil deserved any of the credit. The cough, however, was generally diminished by their influence; but neither the patient's appetite nor strength was materially increased, whilst the olive oil occasionally produced a disinclination for food and slight diarrhoea. It was singular, indeed, to observe the rapid improvement which often followed their exchange for the oleum assæ.

Dr. Cotton's connexion with the Hospital for Consumption necessarily afforded an extensive field for observing and treating phthisis, and this volume shows that he availed himself of these opportunities; and although the subject upon which he writes is sufficiently hackneyed, he has produced a very excellent practical treatise upon it, which deserves, and we have no doubt, will have, extensive circulation.

## NEW INSTRUMENT FOR PERFORMING TRACHEOTOMY.

By M. GERSON of Hamburg.

M. GERSON has lately invented an instrument which is similar to a three-branched speculum in principle, for the purpose of opening the trachea without risk of hæmorrhage. It consists of three branches, which, when closed, form a sharp point, with a shoulder about four or five lines from the point, which will prevent its introduction into the trachea to a greater depth. In order to introduce it, a small incision through the skin is first made with a scalpel, which should afterwards be used to separate the vessels, so as barely to show, with the aid of the nail of the left index finger, the space between two cartilaginous rings. First, fixing the trachea with the left hand, the point is then introduced up to the shoulder, when, by turning the screw, the three blades are separated sufficiently to dilate the ligament so as to allow of the introduction of the canula; the instrument is then withdrawn, leaving none of the consequences occasioned by the flow of blood so frequently attendant upon tracheotomy by the usual modes.—*Prov. Med. and Sur. Jour.*

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, NOVEMBER 10, 1852.

### SURGICAL EDUCATION.

IN our last number we furnished our readers with a sketch of Dr. JACOB'S Introductory Lecture, so far as it had reference to medical affairs in general; we now avail ourselves of the same materials to supply some information, with comments, on professional education in particular. We mentioned in the article to which we allude, that much danger was to be apprehended from the uttering of sham or counterfeit Diplomas, but we were unable from want of space to dwell upon the subject, and now therefore resume it for brief allusion. To our friends in the provinces, it may appear astounding that such a strange method of compensation for the irregular working of the machinery of our medical system should be attempted; but it is even so. Notwithstanding the profuse facilities hitherto afforded for the acquisition of medical and surgical titles to practise, amounting notoriously to a most grievous abuse, the proposal of the day is the multiplication of them. It was not enough that one Irish and three English Universities had the power to grant two different Medical Degrees, one of Bachelor, and the other of Doctor; and that one Irish and five Scotch ones were authorized to grant full Doctor's Degrees; but a new one, or rather an old one revived, is put into requisition for the same purpose: and this notwithstanding the more legitimate authority of three Colleges of Physicians to grant Licences to practise Medicine. If the musty archives of defunct Monastic Institutions be ransacked, we shall doubtless find abundance of materials for the extension of this plan of Medical Reform, and in Ireland especially there is no knowing what may not result from a cultivation of this branch of academic antiquities. From the labours of the Rev. Dr. Todd in this behalf, we gather that

"A school or university of Armagh is said to have been founded by St. Patrick, and was certainly of great antiquity," and that "Caradoc of Lhancarvan asserts that Gildas Albanus, who flourished in the sixth century, and died January 29, A.D. 512, was for some time Master Regent of this seminary," and that "if we may believe Florence McCarthy, who gives, as his authority some MS. preserved at Oxford, the number of students at one time exceeded seven thousand." "Of the school of Clonard, we learn from its founder, St. Finnian, that, under the miraculous guidance of an angel, he was led to a place called *Chath-Bruid*, where his fame soon attracted the notice of the learned, and many illustrious men flocked thither." "Another school of learning, too, was instituted at Ross, anciently Rosnalithe, and still the seat of a bishopric, which is now annexed to that of Cork."

And, doubtless, these Universities had ample powers to grant Diplomas "*in omnibus artibus et facultatibus*." For the diffusion of titles to Surgical practice also, ample provision had been made by the foundation of one College of Surgeons in Ireland and another in England; and by the recognition of three Surgical titles conferred in Scotland; yet this, it appears, did not suffice, for out of the sacred repositories of Durham and Dublin, additional means of increasing the motley medical population have been brought to light. Including the Licences of Apothecaries' Halls, it appears that no less than six-and-twenty parchments are now in the market, purporting to authorize the purchasers of them to practise without being called quacks. On this topic, Dr. JACOB, in his Lecture, observed, that whatever

doubts might be entertained respecting the power conferred or usurped to grant Degrees, Diplomas, or Licences, they may be set at rest, seeing that as any man who pleases can practise Medicine, so can any body of men grant Diplomas; adding, that the Surgeons of Hospitals or the Teachers in Schools could do so. This, in fact, is the true interpretation of the "law opinions" relied upon by corporations exceeding their powers in this respect. They say that, because they cannot be prevented from doing a thing, they have "a right" to do it; and we conclude that, coming from such a source, it is good both in logic and ethics. A Diploma, however, is one thing, and a Degree or a Licence quite another matter; and even between a Licence and a Degree there is a wide difference. In the Lecture to which we are now referring, these distinctions were disposed of by a warning, that however indigent and imperfectly educated persons might rest satisfied with a tainted or disputed title to practise, no man anxious to take his place amongst the Surgeons of Ireland would risk his character by attempting to do so, under any authority less than the Licence of a lawful constituted College of Surgeons, honestly and in truth granted by unsuspected parties. On the subject of preliminary education, Dr. JACOB, in his Lecture, reminded his audience that, notwithstanding the noise made by certain interested parties just now respecting this matter, men, not having objects of their own in view, did not see their way so clearly through the difficulties of the question. He said that "it was all very well to extol preliminary education, but people should first agree as to what that preliminary education should be. Those proud of their academic honours, assumed that the 'classics and science' of a College course was all that was required, but he had his doubts as to that;" and so have we. We shrewdly suspect that certain hallucinations touching the virtues of caps and gowns, and hoods and surplices, with commons and chapels, take the place of sober matter-of-fact calculation of the intrinsic value of knowledge in some men's heads. Sinners as we are, we must fain confess that our faith is not so strong in the virtues of a smattering of Greek and Latin, and a very convenient acquaintance as that of others with what is commonly called "science" by the learned. In the Lecture we have under notice the audience was informed, that the period in their cases having passed for such considerations, it only remained to suggest to all, whether gown'd or not, to acquire the valuable art of writing a letter neatly and legibly, in plain English, correctly spelled. On the subject of professional education, Dr. JACOB, in his Lecture, reminded his audience that the sources from whence they were to draw the knowledge upon which they had to rely for a livelihood were manifold: the dissecting-room, the hospital, lectures, books, and examinations; warning them, at the same time, against the fatal error of relying exclusively upon any one of them, or of rejecting as useless any of them. In the Dissecting-room, they had not only to learn anatomy, but the use of the knife, and in no other way could they acquire that practical acquaintance with the art they proposed to exercise. A falling off in this respect was cautiously regretted, and some hints offered respecting the perversion of the opportunities here afforded to less important purposes; in fact, it seems that the Dissecting-room is not always exclusively devoted to the cultivation of Anatomy in general, and of all parts, but of certain peculiar portions of it, particularly admired by

the Examiners of the day. How far this may be well founded, we do not pretend to say; but if it is, the sooner an amendment takes place the better. Of the Hospital, it was truly said, that there only could the Student acquire the small stock of experience with which he must rest satisfied on his departure from the schools, and there, only could he cultivate the faculty of observation upon which he must rely for future improvement. Here it was that he saw disease in reality, and here he was to take his first lessons in actual practice; every case, however apparently unimportant, being a valuable example; and every operation a demonstration of what the Student had himself to undertake at the first moment of his professional life. On the subject of lectures as a source from whence information was to be derived, a warning was given against the adoption of views hostile to this method of instruction. In this way, the two senses of sight and hearing were made available for the admission of knowledge, and in this way only could explanations, requiring demonstration, repetition, and varied methods of expression, be successfully given. It was true that there were good lectures as well as bad ones; but was this method of instruction to be despised because it was not always perfect? Was the use of it to be condemned because of its abuse? To the Lecture-room the Student was not to come for amusement or excitement, but for valuable information, however communicated; he was not to expect there pratorial effusions, but plain, intelligible, and impressive words, such as they had so often heard from good Surgeons. The lectures of seniors were to be valued for their intrinsic importance as confidential communications, the result of experience; while those of juniors were to be prized for their more recent preparation, and perhaps their greater freshness. Respecting the knowledge to be derived from books, the same caution was given against a blind faith in them, and a rash rejection of their aid. They were no substitute for dissection, hospital, or lectures; but neither were these to be substituted for them. Of this means of acquiring knowledge, there was no want of variety: good, bad, and indifferent, there were; and in some departments, surgery, for example, and physiology, the present generation were fortunate, but so much perhaps could not be said for anatomy. This, we conclude, applied, not so much to any want of books for the Dissecting-room, but to the want of such a perfect system of anatomy as the advancement of this branch demanded; something like a new version of the valuable works of SOEMMERING or MECKEL. On the subject of instruction by examination, irreverently called grinding, "time did not permit the Lecturer to enlarge, nevertheless it was one demanding the most serious attention." Of this there can be now no question, as the substitution of it by many Students for every other species of instruction is too notorious, and this, not for the purpose of becoming good Practitioners, or even to enable them to practise at all, but to pass an examination by a miserable subterfuge which any young man of common capacity and common industry could pass without any such discreditable and destructive evasion. To instruction by examination no objection can be made; on the contrary, it is one of the most valuable means by which the Teacher can operate, and the only one by which the less intelligent Student can be brought to concentrate and give expression to his ideas: but to examinations having no other object but the limitation of a boy's knowledge to the narrow bounds prescribed by a bad system and worse

practice, we emphatically object: it is a vile expedient, disgraceful alike to him who practises it, and him who requires it. On this point we venture to express our opinions freely, because in doing so we express the opinion of every man who has the interests of our Profession at heart: the evil has become so intolerable that we can no longer refrain from endeavouring to correct it, and we are determined, as far as in us lies, to assist in abating the nuisance.

# QUACKERY REWARDED.

A contemporary says, "We are grieved to find that the Cross of the Legion of Honour has been given to the vilest quack whom France ever produced. The man had been for years selling and advertising a wonderful medicine for syphilitic disease, and has now, probably by dint of money, obtained a distinction which, in former times, used to be granted only to men of high attainments, or who had rendered some signal service to their country."

"*Dat Galenus opes*," saith the adage; but it appears from this, he gives honores also; and why not? Many a man wears a coronet won by services no more worthy than quackery. Moreover, who can tell what's a quack these times. MESMER, HAHNEMANN, and PRIESSNITZ, have had better than the Cross of the Legion conferred on them by a discriminating public, and why not allow a Prince to honour a syphilitic philanthropist.

## MEDICAL PRACTICE IN ENGLAND.

THE following is an extract of a communication from the other side, touching the case copied from a Bath paper into our number of the 20th October. It affords information, irrespective of that case, which Irish practitioners may require:—

TO THE EDITOR OF THE MEDICAL PRESS.

"It is, however, to the evidence of the medical witnesses that I would most especially direct your attention; for the course pursued by Mr. Cox is only in keeping with a system which prevails in this country, enabling so many of those who follow it to ride in their carriages, as Mr. Cox, and his volunteer abettors in open court, all do. I leave it to yourself to make the called-for comments upon the evidence, and, perhaps, you may notice, too, how adroitly the "Surgeons" availed themselves of the opportunity of advertising their position and experience; and, above all, the dead hit Mr. Harries made in publishing it to the world, that he would be glad of a hundred such cases at ten shillings each, though Mr. Cox had charged twenty guineas for the case in question. Such, Sir, is the *profession* in England and Wales. You have in this case a perfect exemplification of the system of general practice; and though Mr. Cox has been found out and exposed, I pray you do not think worse of him than of his brothers, generally, of the pill and draught.

And these, Sir, are the hands into which the practice of medicine has fallen; and the physician, who does not court them, buy them, and make "hail fellow well met" with them, has but little chance of getting a living by his profession, except by underselling and supplanting them; and colluding with chequists and druggists, a practice now of such frequent occurrence that the general practitioners are loudly complaining of it, as *disgraceful to the profession*! Alas! for the profession; its days are gone by in England and Wales; for though in the metropolis we have yet a few high-minded and honourable physicians, medicine has become a trade of by no means a very respectable character.

Cases like that of Bourn and Cox are every day occurring, but never heard of, for not one in ten thousand would have the hardihood to come out before the public in such matters as Mr. Bourn has done.

Be it remembered, that the lad who was Mr. Cox's patient was but an apprentice to an upholsterer. Out of such a patient there could be no possible chance of squeezing twenty guineas all at once; and it would not have been Mr. Cox's policy to attempt anything of the kind if the lad were remaining in England. But the lad was going abroad, perhaps never to return, intending, too, evidently, to bilk the Doctor; and Mr. Cox pounced upon him, in the only way he could to get all he could out of him, no doubt, without dreaming that, under such circumstances, a word about the proceeding would ever transpire.

Had the patient remained in Bath, Mr. Cox would ultimately have got his money in a quiet way, by following the course usual in the profession.

He would take, year after year, such instalments as the patient could conveniently pay, the balance due always acting as a *lien* to secure the patient to him as a customer, not only whilst a bachelor, getting out of one scrape only to get into another, but, by and by, when a married man, and requiring a man-midwife in the family. That is the way in which things of the kind are managed; with us, here in England, to get up and rub together practices.

There are no men more lenient to their debtors than our general practitioners are, and upon this principle, that the heavier the load upon the patient in the books, the stronger and tighter are the fetters that bind him to the doctor.

Doctoring, I do assure you, is, on the whole, a very thriving trade in England; yet the fifth of the doctors here could not get a living—not bread and cheese—if they did not resort to such stratagems as we see patent on the face of Mr. Cox's bill.

Notwithstanding this, crowds of young men are every year crushing into the profession.

When, at Dr. Todd's introductory lecture this year, I saw the benches thronged with apparently gentlemanlike young men, I lamented over their destiny, thinking it a pity to see such nice youths plunging into a calling in which the great majority of them must become scoundrels or beggars. I thought, too, of your honest advice to your class on a similar occasion some years ago, which was to this effect, that if they had not the means to support them for many years, till they could, honourably, get into practice, they had better turn, at once, to some honest trade or pursuit whereby to get a living.

Talking on the same subject, and expressing my sorrow for the lot of the young men, to a friend, as I was walking home, he said, "Humbly nonsense, man! they are, nearly all, the sons of apothecaries, bred in the thing, and think it all right; and what you look upon as cheating, they hold to be an essential part of the professional knowledge reduced to practice."

In concluding this I would just remark, that in the evidence of the Bath doctors there is a feature which is worth your notice—the free-and-easy way in which some of them swear, and their evidence upon oath. But, Sir, when it is only a *matter of opinion*, it is easy enough to find witnesses to support either side.

Your constant reader,

AN OLD SURGEON.

London, October 26, 1852.

## RED CLOVER BLOSSOMS A CURE FOR TETTER.

Dr. W. D. Dorris states that he has used the extract of the blossoms of red clover, for the last five years, with success, in the various forms of tetter, by applying it to the parts affected twice a day for several days, washing the parts clean before applying it. It will produce a burning sensation. If it burns too severely, apply the unguentum stramonii. If it is on the scalp, after it is cured, Dr. D. encourages the growth and beauty of the hair by sponging it with the following: Take uncoloured whiskey, one quart; best Cologne, one gill. Mix and shake. It will be ready for use immediately. This mixture will prevent baldness. The extract of red clover is made in the following manner: Clip the blossoms when the dew is on them, with a pair of shears, and put them in a brass or copper kettle with a cover over it; add water enough to cook them; strain, and then boil the fluid over a slow fire until it is as thick as molasses; then pour it into your jars for safe keeping.—*Nashville Med. Jr.*

**SACCHARIZED HYDRATE OF MAGNESIA.**—A preparation under this name has been introduced by Mr. White, of Cork, who describes it as "pure hydrate of magnesia uncombined with any acid, and in the finest gelatinous state," sweetened with sugar, and flavoured with an aromatic. Each ounce contains a quantity of magnesia equivalent to twenty grains of the carbonate. This is a convenient form in which to administer magnesia, especially to children, as it is not at all disagreeable; and the magnesia being suspended, there is no sediment.—*Ph. Jour.*

## DR. BELLINGHAM ON ANEURISM.

Lately published, 12mo, price 4s.

## OBSERVATIONS ON ANEURISM AND ITS TREATMENT BY COMPRESSION.

By O.B. BELLINGHAM, F.R.C.S.I.

One of the Surgeons of St. Vincent's Hospital.

"In our opinion, he has conferred a signal benefit upon the art of surgery by his improvement of the mode of employing pressure, and upon the science by his ingenious and philosophic exposition of its operation."—*Medico-Chirurgical Review.*

"Dr. Bellingham has ably advocated the cause of compression as a highly useful and successful mode of treating numerous cases of external aneurism."—*Lancet.*

"The very excellent and practical essay lately published by Dr. Bellingham, to which we would refer our readers, as containing a most masterly account of the treatment of aneurism by compression."—*British and Foreign Medical Review.*

"I conceive that for a just exposition of the principles on which that mode of treatment should be conducted, as well as for some valuable improvements in the mode of proceeding itself, the surgical profession is mainly indebted to you."—*Sir Philip Crampton's Letter to the Author.*

London: John Churchill, Princes-street, Soho.

Dublin: Fannin and Co., Grafton-street.

## TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

## BROWN'S CANTHARIDINE BLISTERING TISSUE,

PREPARED FROM PURE CANTHARIDINE.

An elegant Preparation, vesicating in much less time than the Emp. Lytte. P.L., easily applied and removed, and will not produce strangury or troublesome after-sore. It has received the sanction and commendation of many of the most eminent Practitioners in the kingdom.—*In Tin Cases, containing twelve feet, 6s. 6d.; and small Cases of six square feet, 3s. 6d. each.*

## BROWN'S TISSUE DRESSING,

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, and may be called a companion to the above.—*In Tin Cases, containing twelve square feet, 1s. 6d. each.*

*Extracts and Editorial Note from the New York Journal of Medicine.*

March 1, 1850.

"BROWN'S CANTHARIDINE TISSUE.—It presents peculiar claims to our notice in the inflammatory diseases of females and children, in whom the unpleasant consequences which so often follow the application of the Emp. Cantharides are most apt to occur. We have found it a reliable and peculiarly safe vesicant, and from the many trials we have given it, we are satisfied that it deserves the attention of the Medical Profession."

"Accompanying this article is a very simple and neat dressing."

*From the Medical Examiner and Record of Medical Science for May, 1850, published in Philadelphia.*

"We have received from Dr. George D. Phelps of New York specimens of Brown's Cantharidine Blistering Plaster and Dressing, with which our readers are doubtless familiar as a new and exceedingly neat preparation, easy of application and certain in their effects. We have given them a fair trial and find they fully answer our expectations."

"Army Medical Department, January 16, 1850."

"The Principal Medical Officer of the General Hospital, Fort Pitt, Chatham, reports that Mr. Brown's Blistering Tissue has been used extensively in the Military Hospital, has been found effective as a vesicatory, when carefully applied, and has not been productive of any degree of strangury."

"ANDREW SMITH, M.D.,

Deputy Inspector-General of Hospitals."

"Mr. T. B. Brown, Druggist,  
Handsworth, Birmingham."

Sold by the Sole Consignee, Mr. William Bailey, Horseley Fields Chemical Works, Wolverhampton; and all wholesale and retail Druggists and Medicine Agents throughout the British Empire.

**PRACTICE OF PHYSIC.**

Dr. BENSON will commence the Course of Lectures on the Principles and Practice of Physic in the Royal College of Surgeons, on Wednesday, the 10th day of November, at Three o'clock p.m.

The Description, Pathology, Diagnosis, and Treatment of Medical Diseases will form the subject of the Course.

Pathological Preparations, Plates, and recent Specimens of Diseased Parts, will be exhibited for the purpose of illustration. The Lectures will be delivered on Mondays, Wednesdays, and Fridays, throughout the session, at Three o'clock.

N.B.—Gentlemen entering the Army are required to attend Two Courses of Lectures on the Practice of Medicine; and those entering the Navy to attend Three such Courses.

Fee for each Course ... Two guineas.

**MILITARY SURGERY.**

Mr. TUFNELL will commence the Course of Lectures on Military Surgery in the Theatre of the City of Dublin Hospital on Tuesday, November 16th, at Four o'clock p.m.

This Course is recognized as equivalent to Six Months Surgery in the professional qualifications of Candidates for the Medical Departments of the Army, Navy, and Ordnance; and by an Order of the India Board, dated March 1, 1852, is rendered imperative upon all Gentlemen educated in Ireland, who may hereafter seek admission into the Hon. East India Company's Service.

**CORK SCHOOL OF MEDICINE**

The Twenty-sixth Winter Session commenced on the 22nd inst., at Two o'clock p.m.

Anatomy and Physiology—H. A. Caesar, M.D.  
Surgery—W. K. Tanner, M.D.  
Materia Medica—J. F. McEvers, M.D.  
Botany—T. Power, M.D.  
Midwifery—W. C. Townsend, M.D.  
Practice of Medicine—C. Y. Haines, M.D.  
Chemistry—W. C. Nash, M.D.  
Natural History—T. C. Shinkwin, M.R.C.S.  
Natural Philosophy—Ed. McCarthy, Esq.  
Practical Anatomy—H. A. Caesar, M.D., T. C. Shinkwin, M.R.C.S., and E. Lundy, M.R.C.S. Eng.

This School, situate on the South Mall, midway between the North and South Infirmarys, has all the requisites for complete Medical Education. Its reputation, for over a quarter of a century, is best tested by the high character of its numerous "Alumni," not only in this city and province, but in each department of Her Majesty's Service, and every quarter of the globe.

DISSECTIONS HAVE COMMENCED.

For particulars apply to Dr. Caesar, South Mall.

October 12, 1852.

**THE MIDLAND RETREAT.**

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY.)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System.

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

**THE COMPOUNDING DEPARTMENT AT**

**G. O. AND CO.'S MEDICAL ESTABLISHMENT**

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

**HOSPITAL SULPHATE OF QUININE, PURE CRYSTALLIZED,**

Prepared by EDWARD HERRING, of the late firm of HERRING, Brothers, for the use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of crystal is the same and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is unbleached and the other bleached. It was originally introduced for the use of Hospitals, Dispensaries, and public Charities, but its purity and great reduction in price is attracting the attention of Medical Men and the Dispensing Chemists.

It is put up in bottles (free) of three ounces and six ounces each, capsuled, with the name of the Proprietor, and labelled with the name of the Inventor. The peculiar mode of preparing the unbleached and white sulphates is being made the subject of a patent, and will shortly be made public.

Both articles to be had of the leading Druggists in London and the united kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Junr., Proprietor,

Chemical Works, Trinity-street, Southwark, London.

October 23, 1852.

**SHIRTS CUT BY MACHINERY.**

**WEBB AND CO.'S**

New System of Shirt-cutting by Machinery enables them to produce really First-class Shirts at prices lower than they have ever yet been offered.

Their Eglinton Shirts,

at 2s. 6d., 3s. 6d., and 4s. 6d. each,

are accurately Cut, elegant in Design, and perfectly sound in Fabric.

A large assortment of Fancy Veined Full-dress Shirts always on hand.

**THE TAILORING AND GENERAL OUTFITTING WAREROOMS**

are now most extensively supplied with every description of WINTER CLOTHING.

**THE READY-MADE DEPARTMENT**

contains an immense variety of

Top Coats, Travelling Coats, Wrapper Coats, Pilot and Frieze Pea Coats,

at 15s., 17s. 6d., and 20s. each,

which, for Workmanship and Solid Value, are not and cannot be surpassed.

WEBB AND CO.,

10, 11, and 12, CORN-MARKET.

## SCHOOL OF SURGERY.

## ROYAL COLLEGE OF SURGEONS IN IRELAND.

WINTER SESSION 1852-53.

The Dissecting-rooms opened on the 1st of October, and the Lectures commenced on the 25th.

Anatomy and Physiology—Dr. Jacob.  
 Descriptive Anatomy—Dr. Hart and Dr. Power.  
 Surgery—Mr. Porter and Mr. Hargrave.  
 Practice of Medicine—Dr. Benson.  
 Chemistry—Dr. Barker.  
 Midwifery—Dr. Beatty.  
 Comparative Anatomy—Dr. Jacob.  
 Dissections by the Professors of Anatomy and the Demonstrators—Dr. Lecson, Mr. T. D. Hargrave, Mr. Malcomson, and Mr. J. Morgan.

## SUMMER SESSION.

Materia Medica—Mr. Williams.  
 Medical Jurisprudence—Dr. Geoghegan.  
 Botany—Dr. A. Mitchell.  
 Practical Chemistry—Dr. Barker.

*The fee for each of the above Courses is two guineas, except Comparative Anatomy, which is free.*

A public course of lectures on Comparative Anatomy and Zoology, free to all students, is delivered by the Professor of Anatomy and Physiology at the commencement of the session, and additional lectures on the same subject at intervals during the winter.

Practical instruction in Operative Surgery is given by the Professors of Surgery, separate from the surgical lectures. Fee, £5 5s.

The Professor of Chemistry receives operating pupils into the Chemical Laboratory.

The following Ordinance was made by the Council of the College on the 9th of April, 1851.—“To enable surgical students to devote more time to hospital attendance and dissection during the winter session, the lectures on materia medica, medical jurisprudence, practical chemistry, and botany, shall be delivered during the summer session in the school of the College, and in the schools recognized by the College; and certificates granted subsequent to the 30th of April, 1851, shall not be received as qualification for Letters Testimonial, unless issued in conformity with this regulation.” Similar regulations have been adopted by the Council of the College of Surgeons of England.

*Hours of Lecture :*

Descriptive Anatomy—Twelve o'clock every day.  
 Chemistry—One o'clock, Mondays, Wednesdays, and Fridays.

Anatomy and Physiology—Two o'clock every day, except Monday.

Surgery—Three o'clock, Tuesdays, Thursdays, and Saturdays.

Practice of Medicine—Three o'clock, Mondays, Wednesdays, and Fridays.

Midwifery—Four o'clock, Tuesdays, Thursdays, and Saturdays.

Dissections from sunrise to sunset; one or more of the Demonstrators being always present to give instruction.

The Professor of Botany will commence a course of lectures on Structural and Physiological Botany in February. This course, taken in conjunction with that on Comparative Anatomy and Zoology, by the Professor of Anatomy and Physiology, constitutes the course of Natural History required by the Army Medical Board.

Pupils attending the Lectures on Midwifery and Diseases of Women and Children are admitted to the practice of a recognized midwifery hospital on payment of a fee of £4 4s.

The Professor of Medical Jurisprudence gives practical instruction in Toxicology in his Laboratory.

## DISEASES OF THE EYE.

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

## CITY OF DUBLIN HOSPITAL,

Upper Baggot-street.

The Winter Session commenced on Monday, October 25.

The arrangements of this hospital are such as to afford the student an opportunity of studying disease in all its forms—Medical and Surgical. The morning visit commences daily at half-past eight o'clock, when the nature, treatment, and progress of each case are explained at the bedside of the patient, and ample opportunity afforded to every pupil of becoming practically acquainted with the uses of the Stethoscope. Clinical Lectures are delivered after the hospital visit.

Connected with the hospital is an extensive Dispensary, at which the pupils are allowed to perform the minor operations, under the guidance of the surgeons, and are rendered familiar with the details of dispensary management.

Every facility is given to students desirous of acting as Dressers and Clinical Assistants, subsequent to which all pupils of the hospital are eligible to the situation of House-Surgeon, according to merit.

A distinct course of Lectures upon Diseases of the Eye is delivered by Dr. Jacob, which the pupils are privileged to attend without additional fee, and special wards are appropriated for the reception of Eye Cases. Extended opportunities are thus afforded for acquiring a thoroughly practical knowledge of this important subject.

A ward is appropriated to the Diseases of Females, and clinical instruction is given upon all forms of Uterine Affection by Dr. Beatty.

Mr. Tufnell's course of Lectures upon Military Surgery is also open to the pupils of the hospital. This course is recognized as equivalent to six months' surgery in the professional qualification of candidates for admission into the Army, Navy, and Ordnance Medical Departments, and is required to be attended by all gentlemen entering the Hon. East India Company's Service.

A Lending Library of well-chosen books has been provided for the use of the pupils; and a correct Registry of the cases in hospital is kept by the House-Surgeon, to which they have free access.

Certificates of attendance on this hospital are recognized by all the Colleges, Universities, and Halls, and by the Army and Navy Medical Boards.

Fee for Winter six months	...	...	Six guineas.
" Summer six months	...	...	Four guineas.
" Nine months	...	...	Eight guineas.

*Medical Attendants.*

A. Jacob, M.D., Fellow and Professor of Anatomy and Physiology, Royal College of Surgeons, 23, Ely-place.

T. E. Beatty, M.D., Fellow and Professor of Midwifery, Royal College of Surgeons, 18, Merriion-square, North.

C. Benson, M.D., Fellow and Professor of the Practice of Medicine, Royal College of Surgeons, 34, York-street.

W. Hargrave, M.D., Fellow and Professor of Surgery, Royal College of Surgeons, 37, York-street.

R. C. Williams, M.D., Fellow and Professor of Materia Medica, Royal College of Surgeons, 14, Lower Fitzwilliam-street.

T. G. Geoghegan, M.D., Fellow and Professor of Forensic Medicine, Royal College of Surgeons, 52, York-street.

J. Tufnell, Esq., Fellow of the Royal College of Surgeons, 58, Lower Mount-street.

*Consulting Physicians.*

Sir Henry Marsh, Bart., and Professor Apjohn.

*Consulting Surgeons.*

Sir Philip Crampton, Bart., Professor Porter; and J. W. Cusack, M.D.

For further particulars apply to Dr. Benson, York-street.

Printed by Thomas Decy, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

### MISCELLANEOUS CASES AND OBSERVATIONS IN THE PRACTICE OF MEDICINE.

By J. KIRBY, LL.D.,  
Ex-Professor of the Practice of Physic in the Royal College of Surgeons, &c. &c.

#### VALUE OF MERCURIAL INUNCTION IN THE TREATMENT OF ERYSIPELAS.

In December, 1845, I published a series of cases in the MEDICAL PRESS on erysipelas, with a view to establish the value of mercurial inunction in that formidable and often fatal disease. I then affirmed that in my opinion it is applicable to the disease in all periods and stages, and this without any reference to the degree of existing fever. I then observed that I use the strong mercurial ointment, and I do not confine its application to the parts diseased alone, but that I extend its use to those parts that, from their immediate vicinity, may be presumed likely to be engaged by an extension of the disease, and I continue its constant use to the third day or so, when the mouth becomes affected, using the remedy more seldom, or wholly discontinuing it, according to the amount of salivary action.

I observed that as soon as the breath is tainted, a marked alteration takes place in the symptoms, evinced by the subsidence of the swelling, the wrinkling of the cuticle, and the abatement of fever, and then that the course of the disease is shortened, superficial sores are prevented, and the formation of purulent deposits is opposed. I will now adduce a case which appears strongly confirmatory of the utility of the practice which I have advocated:—

Mrs. G., a lady, about 45, was seized with erysipelas on the 5th of October last. For some time past, her health was in great disrepair. She endeavoured to remedy what was amiss by warm sulphur baths, of which she had taken three at five o'clock in the afternoon; returning to her home (two miles distant) on an outside car, being indifferently provided against the weather, which was then exceedingly cold.

The attack commenced in her right ear; it slightly en-

## METEOROLOGICAL TABLES.

gaged the upper eyelid, and the face at that side. Living at a distance from town, she sent a very intelligent lady to communicate with me, and to inquire as to the course it would be most prudent to pursue.

I advised two pills, composed of equal parts of pil. hyd. and pil. rhei comp., to be taken at bedtime, and a rhubarb draught in the morning, which was to be repeated, if necessary, in the course of the day.

The lady called the next day, and she informed me that the pills and draught operated abundantly; the erysipelas had not extended; patient was exceedingly weak, and was confined to her bed; she was constantly harassed by a sickness and a desire to vomit, but discharged nothing more than a frothy mucus; the thirst was very considerable. She found cold water to be more grateful than any other drink, and freely indulged in its use.

Knowing a good deal of my patient's constitution, I now prescribed a mixture of decoct. cincho., tinct. cin., carbonate of ammonia, and lemon-juice, to be taken every fourth hour, and I desired powdered starch to be applied occasionally to the affected parts.

The third day I was called to visit her. I found she had taken the second rhubarb draught, by which she was much purged, and was consequently greatly reduced in strength. The erysipelas had extended over the cheek, which was of a brownish red colour, and covered with minute vesicles, filled with an opaque straw-coloured fluid; none of these were broken. The eyelid was much swollen. The nose was more engaged, and the disease reached the brow, and passed down the front and side of the nose. There was much oedema. The pulse was 100 in a minute, and very weak, yet steady. She protruded the tongue with much difficulty, in consequence of an inflammatory fulness at its base; it was clean. The degree of feverishness was slight; she made no complaint of pain in the affected parts, or in her head; was very thirsty, and loathed her food; she liked the mixture, found it agreeable to her palate, and it appeared to calm the sickness of stomach and the fruitless effort to vomit. The urine was natural in appearance, and was regular in quantity. Her voice was

extremely weak. There was a great tendency to sinking, and she required two glasses of wine and some chicken-broth to avert fainting.

Five grains of pil. hyd. and half a grain of watery extract of opium were ordered to be taken at bedtime, and the bark mixture was desired to be continued.

Mercurial inunction was prescribed to the parts and to their vicinity, with many cautions as to repetition. A small quantity of starch was added to the ointment to increase its adhesiveness.

The fourth day the erysipelas had reached the other side of the face, and both eyelids were so tumid as to conceal the globe of the eye. The bowels were profusely free; she was much sunken; the voice was very weak; the pulse was as yesterday in frequency, but much weaker; there was no headache; she has had no sleep for two nights; urine abundant; and the tongue was clean. I ordered as follows:

℞ Carb. ammon. gr. v.  
Mist. cretæ uncias quatuor.  
Liquoris opii sedativ. ʒi. diem.  
Confect. arom. ʒi.  
Aquæ cinnam. ʒii. M.

St. unciam post singulam dejectionem liquidam phiala agitata.

℞ Liquoris opii sedativ. gttss. quindecim.  
Aquæ cinnam. ʒvi.  
Syrupi aurantii drachman. M.

Ft. haustus hora somni sumendus.

The bark mixture to be continued, and the mercurial inunction when necessary.

Vesicat. applicetur nuchæ per horas octo.

As she still complained, not so much of sickness as of pain in the epigastric region which a light pressure induced, and mustard poultice did not relieve, I deemed it prudent to lay on a blister below the xiphoid cartilage for six hours.

She was allowed three glasses of port wine and chicken-broth as heretofore.

The fifth day, the erysipelas had much retired from the right side of the face, but was very great on the left side, over the ear and eyelid. She had some confused sleep during the night, was more sunken than she was on yesterday, notwithstanding her allowance of wine and other remedies, yet she drank well, and carried the vessel to her mouth with a steady hand. She called for her wine and preferred it with water. She took nourishment freely; her bowels were still lax; the vomiting and sickness had ceased since the application of the blisters; pulse regular; tongue clean; there was slight delirium.

℞ Pulv. Doveri, grana decem.  
Pulv. Jacobi, grana sex.  
Confect. arom. q. s. Fiat pilula tres sumat unam tertiis horis.  
Mistura cretæ continuantur.  
℞ Carb. ammon. grana duo.  
Camphoræ granum.  
Confect. arom. q. s. Fiat pilula sumat tertia quaque hora.

Vesicat. inter scapulas per hora sex admoveatur.

The night of the fifth day delirium was so increased, she had continual hallucination, displaying itself in a variety of ways, she was wholly sleepless, and was so sunken since morning, that Sir Henry Marsh and Dr. Duke, who lived in the vicinity, were called to my assistance. They saw the danger which threatened, and recommended the medicines to be persevered in, with Madeira wine, given in small quantities, often repeated, paying due regard to the effect it might have on the pulse.

Cont. inunctio unguento hydrargyri.

That night and the sixth day passed without any sleep, and increasing delirium. The erysipelas had greatly retired from the eyelids, brows, and prominences of the cheeks, on which the vesicles had broken, without any purulent deposit. The eyeball was free from congestion or

inflammation; the pupil was contracted to a mere pin-hole, and was immoveable. She could bear a very strong light, and could tell the hour by a watch after a close examination. She took her nourishment and wine, but did not recognize the taste of anything offered to her. These circumstances were seized on as favourable for the use of opium. Fifteen drops of Battley's sedative was accordingly given, and two drops were administered every hour for three hours. Through this day (the sixth), the pulse sunk to an alarming degree, and was recalled to the wrist by wine; it was 80, and flickering. It called for wine or ammonia every half hour. The delirium became worse; she refused her food and drink, and she quarrelled with her attendants. She did not know where she was, and desired to be removed in the evening. The symptoms became rapidly more desperate. Sir Henry Marsh and Dr. Duke were again sent for; they arrived at twelve o'clock. We all considered the case as all but hopeless; we knew no medicines nor any treatment more efficient than those we had hitherto employed, and we resolved to persevere in them. A slight attack of dysentery now supervened, which we were disposed to attribute to the mercurial inunction, which we thought it prudent to suspend. We prescribed means for its arrest should it be repeated.

It was the seventh morning; the delirium increased. The ammonia, camphor, and Battley's sedative, with wine, and nourishment of the farinaceous kind, were given, when she could be prevailed on to take them. Still there was not any sleep. Blisters were applied to the calves of the legs, but they caused no irritation.

I ordered ten grains of musk in a draught, and repeated it a second time, when she refused it. *A mercurial odour was perceptible from the mouth, and the speech was thick.*

Being much fatigued, I retired to rest for a short period. I had not been in bed many minutes when I was called to my patient, who was sitting by her bedside dressed, and ready for her removal. Her bonnet, which she held in her hand, she thought to be full of horse hair, which she constantly endeavoured to remove. She also imagined there were spots of dirt on her silk dress, which she tried to pick away. Her extremities were perfectly cold, and her face with a clammy sweat, such as is often a precursor of death. Her voice was exceedingly weak, and the pulse, not quick, was scarcely perceptible at the wrist. Madeira wine, given often, appeared to maintain it at its present strength. Her attendants, very properly, did not oppose her in these proceedings, being apprehensive of the consequences of imposing the least restraint; and accordingly she was allowed to remain for some time in her present position. Her weakness now increased, and she seemed to be sensible of it herself. It was proposed to her to lie down and rest herself, which she did under a promise that the car would be soon ready to convey her to any residence she selected.

Her bed being made comfortable, she was assisted to it, and was covered up as warm as she could be made by heated cloths being placed closely everywhere about her person. She had some medicine, with a dose of Battley's sedative introduced into it. In a short time she was fast asleep. Reaction had taken place; she was hot, and perspiring, awakened in an hour, was much composed, and was satisfied to remain in bed some time longer; she asked for some wine, which was given, with Battley's solution, as heretofore, and she was soon asleep again. She was now watched most narrowly. On every occasion when she awaked she had some stimulant, but with the greatest caution, taking as much care as possible to give neither too little nor too much. The next day and succeeding night were periods of great watchfulness and inexpressible anxiety.

From this period matters began to brighten; the medicines were carefully administered, especially the pills composed of ammonia and camphor. Wine, tea, and light nutriment were given in small quantities as her periods of being awake permitted.

Pursuing this plan, her mind began to recover, and in

another day raving had altogether ceased; the face scaled generally, and threw off large flakes coloured by the mercurial ointment, which was laid aside on the mouth being sore, as it now was in some degree.

A number of boils now broke out over the epigastrium, the neck, the back, and in some inconvenient situations. They were accompanied with much distress. I applied to them a solution of nitrate of silver in the proportion of a drachm to an ounce of distilled water; this gave great pain at the time, but was of much service where it was applied, in subduing the attendant irritation and fretting soreness.

For some nights she required Battley's sedative to induce sleep. The dose, however, was gradually diminished until its final discontinuance. The stimulants, too, were lessened in proportion as more generous nutriment was permitted, until at length she was reduced to the quantity admissible in health. She was now convalescent.

(To be continued.)

#### EXAMPLE OF HERMAPHRODITE FORMATION.

By SAMUEL STUART, Esq., Donaghadee.

THE following case, the particulars of which I here give, came under my notice a short time since. I deem it sufficiently interesting to bring before the profession on account of the imperfectly developed state of the generative and urinary organs, and the irregularity in their distribution and arrangement:—

On the morning of the 3rd of October, 1852, I was called to attend Mrs. G., the wife of a butcher in Donaghadee. It was her fourth confinement. She had brisk pains, the head presenting, and in a short time she gave birth to a fine healthy-looking child; this was followed in about half an hour by another, also a head presentation; both children were of full average size, the younger a female, and the elder in every way well formed except the organs of generation, which present a considerable deviation from the usual appearance.

It is furnished with a double scrotum, which occupy, respectively, the situation of the labia majora in the female; each scrotum contains one testis. On the inner side of the right scrotum, in close connexion with it, and pointing towards the left side, is a small sized penis, about a quarter of an inch in length, or, more properly speaking, a glans only, with a prepuce, which is mostly retracted; by this rudimentary penis the urine passes freely. In the space between the scrota are two openings of a circular form, capable of admitting a probe or small quill, and separated by a thin membranous septum. These openings occupy the situation of the urethra and vagina in the female, and seem to represent those organs; indeed, the upper one is a *real urethra*, the urine passing regularly through it, also in a full stream, though *not at the same time* that it passes by the penis, thus showing, I believe, that there are two bladders. Whether the lower opening, which seems to represent the vagina, may lead to a uterus, I cannot say, though the presumption is that it does. At the point of junction of the scrota inferiorly, at the anterior margin of the perineum, a fleshy vascular tumour projects, about an inch and a half long, of an irregular pyriform shape. It has, about a week since, begun to discharge a dark, glairy fluid, which has reduced it in size, and it seems likely soon to disappear altogether. The child is healthy and thriving, and likely to live, as any child of its age.

This is a good, brief account of this species of congenital malformation, and better because it is brief. Such a one was exhibited at the Surgical Society last season, but no description of it was published in the Transactions. Notwithstanding the care with which such deviations from the natural or regular organization have been investigated, the subject admits of farther illustration, and so therefore is this short notice acceptable.

#### SCIRRHOUS CONTRACTED STOMACH.

By W. W. SANDHAM, Esq., Cork.

THE following is a report of an autopsy held on the body of Mrs. B., aged 50, at an inquest in Cork, June, 1852, the husband being accused of causing her death by giving her a blow on the stomach six months before. Dr. Fowler was present:—

For a considerable time she complained of a lancinating pain in the region of the stomach, which she described to me (or I attended her previous to death) as if caused by suddenly thrusting a blunt knife through the organ, and immediately withdrawing it; constant vomiting of anything taken into the stomach, and a pulsation of the aorta beneath, which appeared unnatural; soon after taking drink a tumour would arise, and appear to occupy the region of the stomach, which by gentle pressure with the palm of the hand could be emptied. This phenomenon she could produce in a few moments at pleasure.

*Autopsy.*—The body was emaciated to an extreme degree. The skin was contracted to its utmost, and of a dark-brown leathery appearance. On making the abdominal section, the scalpel moved with the greatest difficulty through it. On separating the parietes of the abdomen, no appearance of anything like a stomach was visible. The liver was healthy, but small, and the left lobe completely concealed the stomach. All the other viscera were healthy, the intestines being very pale, and beautifully transparent. On passing the hand up under the left lobe of the liver, I found what was a stomach, but now had no resemblance to such an organ, tightly drawn up against the diaphragm, and was with some difficulty drawn down into view. It resembled a portion of intestine, about six inches long, and scarcely an inch and a half in diameter, whose coats were thickened and indurated, indeed semicartilaginous. The cartilaginous deposit extended the whole length of the superior or concave edge, from which, at regular intervals, three or four rib-like processes proceeded at right angles, anteriorly and posteriorly, and terminated in points near the inferior, or, what ought to be, the convex edge. On slitting it open it was empty, and could not contain more than a wineglassful of fluid. Near the pyloric extremity was a tumour, projecting inwards, about the size of a hazel nut, of a scirrhus hardness, and appeared the nucleus or centre of the disease. The whole organ was of a dead-white colour, no appearance of vessels ramifying through it, nor was the mucous membrane ulcerated in the least, and if separated from the body and shown to any anatomist living, he would not say that it was a human stomach: any fluid drank must have passed through it as through a cylinder of wood.

The aorta beneath was no more than the natural size; and the tumour that used to form during life, leading one to suppose that it had a direct communication with the stomach, was produced by the colon, when distended with fluid or flatus, rising up and appearing in front of the stomach.

From her having complained previous to the blow received from the husband, and the extraordinary change produced in the organ, Dr. Fowler agreed with me that the disease was produced by natural causes, and was decidedly *scirrhus* in its nature.

This state of stomach has been seen before; but it is well described here, and is worthy of attention. We prefer such brief matter-of-fact descriptions to more glowing recitals. There is a place in Dublin where certain Doctors meet to exhibit the results of their practice, much in the same way that Indian warriors assemble to count their scalps: this stomach in the hands of any of them would have created quite "a sensation," but coming from Cork, and published in the Press, it will make no impression.

## OPHTHALMOLOGY.

## OPHTHALMOLOGICAL GIMCRACKS.

The following account of some of the "new found old inventions" of the day, proves that this branch of surgery is still in the hands of men who do not understand it. What a power must be given to the use of simple instruments, and what a better means of realizing ophthalmological character, there is no end of these miseries. The journal from which we quote is famous for its patronage of the gimcracks and jawbreakers of "ophthalmology."

## NEW INSTRUMENT FOR THE OPERATION FOR CATARACT AND FOR ARTIFICIAL PUPIL.

By Dr. FURNARI.

The principal application of this instrument is to entirely remove adherent portions of the capsule, and thus prevent the formation of secondary cataract. The needle, fixed in an ivory handle, is of the same size as Scarpa's; it consists of a stem ending in two perfectly equal branches, which unite to form a slightly curved point, and having their internal surfaces toothed, to seize the pieces of opaque capsule. A sheath, extending into the interior of the handle, accompanies the needle as far as the base of its point. The instrument is moved by means of an apparatus in the handle. By pressing on the lever the sheath is withdrawn into the handle: the needle then separates, seizes and detaches the opaque bodies which obstruct the pupil, and when the thumb is removed from the lever, the needle again closes, forming a true forceps. The advantage in this instrument is, that pressure on the lever opens the blades of the needle, by which it is rendered more easy of appliance than when constant pressure is required to keep the instrument closed. Dr. Furnari also describes a forceps-knife (*couteau pince*) and a forceps-curette (*curette pince*) on the same principle. —*Lond. Jour. of Med.*

## NEEDLE FOR DEPRESSING CATARACT, AND A NEW INSTRUMENT FOR SECTION OF THE CORNEA.

By M. LANGIER.

Almost every surgeon must have experienced the inconvenience of the ordinary cataract needles, with a fixed point. Displacement of a fragment of the lens, or of a portion of the opaque capsule, can only be effected by making the lancet describe extended arcs of circles, having as a centre the point of the sclerotic traversed by the instrument. The extent of these arcs leads to too great lacerations of the hyaloid membrane, and sometimes even to injury or detachment of the iris. M. Langier believes that these difficulties and dangers may be partly avoided by articulating the point on the stem of the needle, the point being moved by means of a lever in the handle, like the key of a flute. By means of this modification, the centre lens, or a portion of its capsule, or false membranes, may be readily removed from the field of the pupil. It may be introduced quite straight into the eye; and, when arrived in front of the cataract, may be placed at any angle which the operator may desire, and is susceptible of alternate extension and flexion, according to the object which it is proposed to attain. The motion of the point resembles that of the third phalanx of the fingers; and it would be very easy to make an instrument with two joints, which, however, M. Langier has not yet found necessary. With a single joint, the movements of flexion and extension of the point may be subservient to a number of purposes, such as in breaking up the cataract, tearing through its adhesions, and even forming artificial pupil, either by tearing down adhesions, or by detachment of the iris.

M. Langier has also combined with the jointed needle a concealed cornea knife, by which he believes that the section of the cornea will be made more surely than with the scissors of Richter or others. This keratome, at the end of which is the articulated point, is a little larger than the ordinary needle. It is much like a lithotome with a

single blade; but the blade is not contained in a sheath, which would uselessly increase the size of the instrument, but it is merely applied to another blade, with blunt edges, which cover it, and which contain the spring for moving the point of the needle.

In operating, a large opening may be made in the capsule by the point of the needle, which is directed towards it through the dilated pupil. It will then penetrate the lens, and bring it, either by the movements which may be communicated to it, or by simple pressure above or below, into the anterior chamber. In withdrawing the instrument by the passage by which it has entered, the blade of the keratome separates from the flat stem on which it lies, and incises the cornea, for a fourth or third, at most, of its diameter. This incision is long enough in most cases. One advantage of the concealed cornea knife, M. Langier states to be that of incising the cornea from within outwards, so that the deep layers of the membrane are cut to the same extent on the superficial.

In the wood-cuts which accompany the description, the motion of the keratome is represented as being regulated by a ring in the handle of the instrument. —*Id.*

Although it is not very probable that any of our readers will trouble their heads or pockets with "Dr. Furnari's" invention, it may be as well to tell them that it is quite unnecessary to remove portions of an opaque capsule from the eye, unless very large, very thick, and very hard. With a proper needle (not a cutler's awl with an ebony handle and silver ferule, but a fine needle curved at the point), any man who has the use of his hands can detach fragments of capsule, and leave them to retract behind the iris, or to be absorbed. When the opaque capsule is very large, thick, and hard, it must be extracted, through an incision in the edge of the cornea, by means of a fine forceps or hook. Of "M. Langier," his depressor, it is the same. Any botch with any needle can depress a cataract; but the great difficulty is to keep it depressed, which this contrivance will not do, but on the contrary will prevent. The following we print by way of specimen. It is a precious sample of ophthalmological egotism and vain-glorious boast. The "thoroughly satisfactory cures," the ten years' study of "minute bodies," and "with a microscope" too, as well as the valuable statistics, are highly characteristic. Then the "thirty-seven thousand one hundred and ninety-nine" patients, in italics; the smiths, the stone-cutters, the millers, the turners, and so on. How accurate! So likewise the objects from the "organic and inorganic world," the "vegetable tissues," and "animal bodies." The manufacture of iron rings by palpebral friction is, however, best of all. We advise a perusal of a chapter in some book on eye-surgery, touching foreign bodies in the eye, by "the author":—

## EXTRANEOUS SUBSTANCES IN THE EYE.

By AUGUSTINE PRICHARD, Esq., Bristol.

(Read before the Bath and Bristol Branch of the Provincial Medical and Surgical Association, October 7, 1852.)

The detection and treatment of the symptoms produced by foreign bodies in the eye, are matters of considerable surgical interest, dependent upon the value of the organs implicated, the destructive results of inefficient surgical aid, and the thoroughly satisfactory cures obtained by the most simple measures. Besides this, the subject is a surgical curiosity. Having constantly under my care a number of these cases, I have for ten years past always examined with a microscope the minute bodies which I have removed from the surface of the eye, and might perhaps be supposed, have met with a considerable variety.

It will perhaps make my paper more worthy of a scientific body like the present, if I first give some account of

the numbers of accidents to the eyes, in proportion to the whole number admitted to an ophthalmic charity, of the percentage of accidents where a foreign substance still remains in the eye at the period of admission, of the numbers of the different kinds of substances found, and the occupation of the applicants. I will afterwards show to any who feel disposed to examine them, some of the objects I have prepared.

My observations are collected at the Bristol Dispensary for the cure of complaints in the eyes, founded by Mr. Estlin in 1812; and they go back as far as the year 1834, from which time the various injuries have been more distinctly arranged under their separate heads than they were before. This comprises a period of eighteen years, during the first part of which I attended the Eye Dispensary as pupil, and for the last ten years as surgeon.

Thirty-seven thousand one hundred and ninety-nine patients have been admitted during this time, that is about 2100 in every year, upon an average, 2856 of these patients were injuries to the eye, being between seven and eight in every hundred.

From this number of accidents we must take those that bear upon the present subject, and they are the following:

		Per cent.	
1. Injuries from lime.....	175	= 0.497	Of whole No. admitted.
2. Pieces of iron or steel on the } cornea .....	650	= 1.74	
3. Other foreign substances.....	524	= 1.40	

I need not particularly describe the symptoms of an extraneous substance in the eye, as all have experienced the sensation, and must know that it leaves little room for doubt as to diagnosis. It must be remembered that the lid is the most sensitive part, and feels in the act of winking the foreign body stuck upon the globe of the eye, and the patient himself always refers to the upper eyelid as the position of the offending substance. The treatment is of course to remove it as speedily as possible, and for this purpose we ordinarily use a silver instrument, shaped like a cataract needle, considerably curved.

There are one or two observations I wish to make respecting the mein of a patient with an extraneous body in the eye. Some of the diseases of the eye are always accompanied by peculiar mein or characteristic gestures on the part of the patient. A child, with strumous ophthalmia, is brought into the room backwards, shrinking from the light, with both eyes screwed up as tightly as possible, with a handkerchief pressed up against them. A man with amaurosis walks in with his eyes widely staring and his brows raised, so as to prevent the possibility of any rays being intercepted in their progress to his insensitive retina. A patient with cataracts has his eyes partially closed, his brows contracted, and his hand raised to shade the eyes, to allow the iris to dilate as much as possible, and in a patient with an extraneous substance in the eye, one is entirely closed, or if opened for a moment, is immediately closed again; he shows great incapacity of keeping his eyes open, which gives rise to the peculiar appearance of intolerance of light with one eye only, the other being in a great majority of cases quite sound. I have constantly noticed that the mein or general appearance of such a patient and of the eye (in a casual examination) exactly resembles that of a man with iritis, which disease most commonly attacks one eye; and if inflammation has been produced by the extraneous substance, the redness is more like that in sclerotic inflammations than the colour of the eye in affections of the conjunctiva. There is another point of resemblance, which is one of particular physiological interest. It is commonly taught, and believed that the optic nerve is the only afferent nerve to the third or motor nerve of the iris—i.e., that the pupil contracts only when the optic nerve feels the impression of the light, and takes it back to the brain, sending the message to contract along the third nerve through the ciliary ganglion to the iris. Persons with an extraneous substance adherent to the cor-

nea of one eye, almost invariably have that pupil contracted than the other, notwithstanding the fact that the eye is kept more closed. The explanation of this is, that the fifth nerve distributed on the lids, feels the irritation, and acts as an afferent nerve to the iris, which immediately contracts. I some time ago brought forward a proof of this fact, or of one exactly similar in nature, from the Blind Asylum Report. Two other instances have come under my notice recently. A girl completely blind from amaurosis after fever, and unable to distinguish the least light, was exposed to the rays of the sun. I saw the pupils of her eyes instantly contract, as in a seeing eye, and she said that she knew she was in the light from the sensation. With another blind person, whose eyes were completely sunk, and where there was no perception of the light, I performed the same experiment. She had no iris to contract, but she began to wink her eyelids, and the tears began to flow from the weakness produced by a bright light, exactly as would happen in a seeing person exposed to the same influence. These facts prove beyond question that the fifth nerve feels the light and acts as an afferent nerve to the iris and eyelids as well as to the optic nerve.

I leave out of our present consideration all cases of accident, except where there have been extraneous substances adherent to the surface of the eye, and this is a tolerably numerous class, 1174 having presented themselves, amounting to one out of every thirty-one. I need scarcely say that very few of these were women.

The artisans of a large city who most commonly come for aid on this account, are the following:—

*Smiths*, with scales of hot iron, which have struck upon the surface of the eye in hammering red-hot metal.

*Stone-cutters*, with minute portions of their chisels, or more rarely, of stone.

*Millers*, who have to chip the millstones, and thus also get struck with pieces of metal or stone.

*Millwrights*, with pieces of steel on the cornea.

*Boiler-makers and engineers*, as they call themselves—i.e. engine-makers, who are particularly liable to get pieces of iron in the eye, in chipping cast-iron, or hammering the rust from old boilers, or in grinding.

*Metal turners*, as opticians' working men, &c., who are struck with minute points of brass or iron; these generally have thin pointed pieces, like the tip of a needle, driven into the eye, where they penetrate perpendicularly and adhere most firmly.

*Carpenters*, in hammering or grinding their tools.

*Tilers, plasterers, and masons*, in building and breaking stones, and hammering the plaster from walls; or what is still more frequent, in driving the nails into the laths in their plastering business. The nails generally used are cast and cut by machine, and are extremely brittle.

We see from the country—

*Colliers*, from the numerous coal mines in the neighbourhood of Bristol, with pieces of coal in the eyes.

*Farmers' labourers*, who are injured in chopping trees, or hedging, or haymaking.

We must add to these, of course, all the little accidents that occur, as for instance in railway travelling or in a dusty road, which are entirely independent of the patient's employment, and may happen to any of us at any time.

I have encountered objects from the organic and inorganic world—in fact, animal, vegetable, and mineral substances of various kinds, some one or two of each of which I should like to show you.

Of vegetable tissues there have been specimens of wood, in the form of chips, imbedded in the cornea, or under the lid; or minute pieces of bark, which have flown from the edge of the hatchet; portions of nutshell, seeds, and grass. One specimen of hard woody structure shows the separate wood-cells very distinctly, but from what plant it comes I have not been able to determine.

The animal bodies, which I have had occasion to remove from the eye, have been minute flies, of various kinds, more or less entire, and the wing cases of insects—that is, the hardened case or shell, in which are folded the inner or real wings of the coleopterous tribe of insects. They are

concave on one side, and convex upon the other, and adhere very firmly to the cornea, in all probability with the action of the leather sucker by which boys raise stones—i.e., by atmospheric pressure. An instance occurred in the year 1839, when the patient presented himself, after suffering pain and inflammation of the eye for ten months, and the removal of the wing-case relieved all symptoms. There is sometimes a little difficulty in detaching them from the surface of the eye. Many of them are pretty objects for microscopic examination, they are very minute, and I have removed several in an entire state.

**Metallic substances.**—Pieces of percussion caps—of iron, brass, or copper, retain their metallic appearance, if they are entirely imbedded in the substance of the cornea, and are thus removed from the action of air and moisture, so that after removal they have the glistening appearance of a metallic surface; and in the case of iron, it is attracted by the magnet. Portions of percussion cap are generally more or less imbedded in the eyes, as the accident is always accompanied with considerable force. Pieces of lime and stone will adhere for some time to the cornea.

One of the most remarkable facts connected with these metallic bodies in the eye, is seen when a piece of iron is driven upon the surface of the cornea, and does not penetrate deeply, but is subjected at once to the double force of friction by the eyelid, and oxidation by exposure to the air and tears. If it remains a few days in the eye, an extraordinary change takes place in its form, for it assumes the shape of a minute iron ring, with a clear central hole. Of this curious fact, I have numberless proofs in the shape of specimens, which I have myself removed from the eye, and which I shall be happy to show you. Now, this ring is formed in two ways—the small piece of iron adheres to the cornea, and the prominent part is gradually rubbed away by the lid until it becomes transparent in the centre, much as an optician grinds a concave lens; the other method is when the circumference of the minute piece of iron adheres as before to the cornea, and the prominent centre is gradually loosened, and removed *en masse* by nature or art. Of the former of these methods—i.e., the gradual thinning of the minute point, I have proof in specimens showing all the stages until a clear ring is formed; and as to the latter, I have frequently removed with the silver curette a central point, leaving a ring behind, which I have detached at once, or after a few days. These rings are frequently only oxide of iron, and not metallic iron, the occasional transparency showing that they are then no longer in the purely metallic state. I do not yet understand clearly why these pieces of iron are so generally circular as is the case; they either fly off from before the hammer hot and fused by the violence of the blow, or they are ground of a circular form between the lids and the globe of the eye.\*—*Prov. Med. and Surg. Jour.*

\* One piece of vegetable cellular tissue went through a somewhat circuitous route, before it finally rested as one of my microscopic objects. A man presented himself with an acutely-inflamed eye, with puriform discharge, and on evertng his upper lid, a foreign substance was seen, and removed, which turned out to be the cellular membrane of some vegetable. The history was this:—a few days before he met and entered into conversation with a friend (a butcher's boy), carrying a *bullock's paunch* in his hand; from words they came to blows, and my patient was brought down by a heavy flap in the face from his adversary's disagreeable weapon. His eye was painful, and intolerant of light, from that time until the substance was removed, when it speedily recovered. The portion of vegetable matter, having escaped in the process of rumination and digestion, found its way thus abruptly into the man's eye, and thence into my possession.

## MEMBRANOUS CROUP SUCCESSFULLY TREATED BY TRACHEOTOMY.

By DANIEL AYRES, M.D.,

One of the Surgeons to the Brooklyn City Hospital, New York.

To the unprofessional observer *all* forms of croup are identical. The special attention of medical students and the practical observation of most physicians is confined to two varieties—1st. False or spasmodic croup is attended with little more disease of the larynx and air-passages than disordered functions. It is generally a secondary or symptomatic disease, short in its duration, and amenable to very simple treatment. 2nd. True or membranous croup is an inflammatory disease attended with fever. Commencing in the larynx, trachea, or bronchial tubes, it may extend to the lungs or even pleura, and is characterised by the effusion of tough plastic material into these passages, thereby preventing the ingress of air and proper aëration of the blood. It requires active antiphlogistic and emetic treatment, but unfortunately is generally fatal.

A third variety called follicular stomatitis or diphtheritis is a well-marked form of disease often confounded with the second variety; but whilst it differs therefrom in the locality of its origin, strongly resembles it in the mode of invasion, symptoms, duration, tendency to spread, in the plastic character of its effusions, and fatal issue. Indeed, so striking is this analogy, that excellent authorities have doubted the existence of any material difference in these two last forms of the disease, and this uncertainty may be greatly augmented when it has existed several days before medical aid is sought. It is when medication in all its forms has failed to arrest the disease, and human life is threatened, that surgery has been invoked to clear the avenues to the lungs, and then a correct appreciation of the condition and parts involved may be of immense moment to the victim; so that even in cases of doubt, the benefit of that doubt may not be withheld.

But here the operation of tracheotomy has now fallen into complete desuetude as a rule of practice, and this because, as applied to the second variety, it too often presents few advantages, and least of all when undertaken *in extremis*. So unfavourably is this operation esteemed by the profession, that it is often difficult to obtain counsel to justify its performance, or the friends of patients to sanction this last chance for life. It is from these causes, together with the miscellaneous confounding of different phases of the disease, that we now rarely hear of the operation. Its success under such discouraging circumstances becomes an important practical fact to the profession and the public; for after all the latter are alone called upon at the last terrible moment to decide the case, and the prospect of success held out by the resources of our art may have great weight in that decision.

These observations are fully illustrated by a case which I saw in consultation, at the request of Dr. Palmedo, a highly intelligent physician of this city, on the sixth day after the invasion of the disease. Dr. Palmedo, who had been associated in the case but the day previous, and watched it with intense and self-denying anxiety, has very kindly furnished copious notes, from which the following history is collated:—I. M., aged four years, of light complexion, rather delicate constitution, but otherwise perfectly healthy, had suffered several attacks of croup since his second year. About the middle of March last he contracted a common catarrh, the result of undue exposure to cold and wet. On the 19th, the cough, which had been troublesome, began to assume a peculiar hoarse sound, and was soon followed by rapidly increasing dyspnoea. The real nature of the case was mistaken for a catarrhal affection of the tonsils, and afterwards for spasmodic cough, under which supposition *pulv. mastic. grs. viij.* had been given in divided doses during Monday night. On Tuesday, the 23rd, the symptoms becoming alarming, the parents of the child felt the necessity of calling additional medical aid, when the disease was recognized at the first sound, even before entering the sick room. The little pa-

FEVER AND CHOLERA.—The yellow fever is ravaging Barbadoes, and a great many of the coloured population have fallen victims to it. Deputy Assistant Commissioner Neal died on the 4th inst. and within four days, his wife, four children, and a large number of his slaves, with the dead. Cholera and small-pox are committing frightful ravages in California among the Indians.

tient being in imminent danger of suffocation, a sponge saturated in boiling water was instantly placed upon the region of the larynx, with a view to produce slight vesication. Subsequently six large leeches were applied to the neighbourhood, and whilst still freely bleeding, a copious emesis was effected by the annexed powders :

℞ Sulphatis cupri, grs. xviii.  
Sach. alba. ʒj. Mix.

Divided into six equal parts, one of which was administered every ten or fifteen minutes.

To prolong this effect, the following mixture was administered :

℞ Potass. tart. antimonii, grs. iv.  
Pulv. rad. ipecac. ʒj.  
Oxymel. scillæ, ʒij.  
Aq. destil. ʒ.

A dessertspoonful repeated every ten minutes for half an hour.

Large quantities of thick viscid slime, and several masses coagulated in the form of membranes and strings, were thus ejected. In about an hour and a half from the commencement of this treatment, all the urgent symptoms began to subside ; the face became quite pale ; respiration slow, perfectly easy, and scarcely audible ; the cough less frequent and loose, was followed by copious expectoration ; pulse 80, soft and small, with a cool and moist skin ; sleep soon succeeded, the first that had been experienced for two nights. He was, however, directed to be aroused every hour for the alternate administration of the following mixture and powders :

℞ Ammon. muriatis,  
Pulv. glycer. aa. ʒi.  
Vini antimonii, ʒjss.  
Oxymel. scillæ, ʒij.  
Syrup. simp. ʒj.  
Aq. anisi, ʒij. Mix. Dose ʒij.  
℞ Hydrarg. submur. grs. vj.  
Antim. sulph. aurar. grs. iv.  
Pulv. g. acacia, ʒss. Mix.  
Div. in chart. No. vj.

In addition, an aperient enema was given, and emplastr. vesicat. two inches by two, applied to the throat. Thus the night was passed quite comfortably, and strong hopes entertained for the child's recovery.

24th : Towards morning, however, the respirations became a little more hurried and wheezing ; pulse 100 ; cough dry and more frequent. The above-mentioned powders having been exhausted, were repeated, and given every alternate hour with ʒij. of the following mixture :

℞ Potass. tart. antim. grs. ij.  
Syr. senega, syr. ipecac. aa. ʒss.  
Oxymel. scillæ, ʒij.  
Aq. anisi, ʒij. Mix.

Towards noon, the respiration became more difficult and wheezing ; a slight mucous râle discovered in the lungs, and a louder râle in the trachea ; occasional harsh cough ; expectoration very scanty ; pulse 110. Anticipating an extension of the disease to the lungs, three more leeches were applied over the sternum, and the following cathartic given :

℞ Submur. hydrarg.  
Pulv. jalap. aa. grs. x. Mix.

About one p.m., a copious and fetid discharge took place from the bowels, after which the pulse and respiration were somewhat relieved. An unfavourable prognosis was, however, entertained, anticipating another relapse. This actually supervened about six p.m. Each inspiration became more wheezing or whistling, and laborious in the extreme, with extraordinary contractions of the diaphragm, aided by all the voluntary muscles. Cough dry, rough, and barking, but less frequent and strong than yesterday. Occasionally a loud râle was detected in the trachea, but no expectoration, and there was now perfect aphonia.

At nine p.m., he was rapidly exhausting with paroxysms of intense excitement and agony ; the whole body thrown into convulsive action whilst struggling for breath, under a sense of impending suffocation. Between these attacks,

he lies listless, half unconscious, with eyes closed, face and lips livid, countenance pinched and sunken ; pulse 120 and weak, but still sufficiently distinct to be counted ; cool perspiration over the forehead ; extremities yet warm ; thorax resonant on percussion and respiration ; when it could be heard, puerile. All hopes from emetics, and in fact from any medical treatment, was abandoned ; and in answer to the urgent entreaties of distracted parents and friends still to do something for the relief of the sufferer, Dr. Palmedo proposed tracheotomy as offering a slight but yet the only hope of salvation. In this condition, I was requested to see the child, and anticipating operative proceedings, desired my friend Dr. Cochran to join the consultation. Death seemed inevitable, and the child being now almost past consciousness (at least of pain), the operation was urged purely as a matter of duty, and finally assented to, but without an expectation of success.

At ten p.m., the child being placed on a table, with the neck well raised, and made tense by depressing the head, I commenced a longitudinal incision just below the cricoid cartilage, one and a half inches long. Carefully dividing the fasciæ upon a director, and separating the muscles, several large veins were brought into view, and pressed out of the way by curved spatulas. The thyroid isthmus interfering, was divided and compressed with very little hæmorrhage. A free opening was then made into the trachea, into which air rushed with great force. A medium tracheal tube was now introduced and secured with tapes, compression above and below the wound being effected by adhesive straps. By means of a long feather, some tough shreds of membrane with viscid mucus were removed. In a few moments, the natural respiratory movements of the chest became slowly perceptible, and in an hour the calmest and most regular breathing was established, colour and life returned to the face, and the child was asleep. When awakened, he was perfectly conscious and comfortable, drank two tumblers full of water during the night, coughed frequently, and ejected large quantities of viscid secretion, which continually accumulated in the tube, and required removal with a feather.

25th : Towards four o'clock in the morning, the respiration became more frequent and laborious, and the cough dry. On introducing the feather through the canula, a solid substance could be felt blocking up the trachea, but nothing could be thus extracted. The symptoms again seemed threatening suffocation ; however, by insinuating the feather about four inches into the trachea and beside the obstructing body, such a violent fit of coughing was produced that a hard fibrinous mass, an inch and a half long, and of similar calibre to the tube, was thrown out and to a considerable distance, whereupon the child dropped away, quite exhausted, and fell asleep. Several smaller masses, with a vast quantity of thick, reddish, and glutinous slime, were expectorated during the whole day ; between the intervals of the cough, the child appeared quite easy, and took some beef-broth.

In the afternoon, between four and five o'clock, the symptoms again became aggravated, and suspecting obstruction of the canula, it was removed, cleansed, and replaced. But still the respiration continued frequent, difficult, and noisy, in consequence of accumulated exudation in the trachea which could not be dislodged. At length, a piece of sponge secured to the end of a curved probe, and saturated with the following solution

℞ Argenti nitratis, ʒij. cum aq. destil. ʒj.

was introduced through the canula into the trachea, about four inches in all. The momentary effects of this operation were terrific. The child twisted and writhed seemingly in the greatest agony, leaped up in his bed, and made every possible effort to blow through the tube. It was the last struggle for life, a few moments delay and suffocation seemed inevitable ; but by a final and still more vehement paroxysm of coughing, another mass of concreted fibrinous matter, two inches long, was blown up high in the air, when the same happy change took place as in the morning, followed by sleep and a comparatively easy night. Of

the following mixture, he was directed to have a teaspoonful every two hours:

R. Liquor. potass. ʒij.  
Acet. scillæ, syr. ipecac. aa. ʒj.  
Mucil. g. acacia, ʒij. Mix.

A free secretion of mucus took place after the introduction of the solution, and to obviate its desiccating in the tube, thereby preventing the free transit of air, the internal surface was lubricated with oil of sweet almonds, and every five or ten minutes a few drops of warm water were introduced by means of a feather. The expectoration was evidently much facilitated by this simple imitation of the natural condition of the air-passages. The tube was daily removed without trouble, the symptoms of the child continued to improve, and the secretions of the chest gradually verging towards a healthy condition.

28th and 29th: It was unnecessary to remove the tube, which was readily cleansed by the swabbing, and on the following day a new tube with a large oval opening in its posterior wall, was substituted for the old one, through which some air was found to pass by the larynx.

April 6th: On removing the tube, the child for the first time cried and spoke, but seemed frightened at its own voice. 9th: The air-passages being now tolerably free, the tube was removed, and its place closed by adhesive straps; the voice is a few notes higher than before. 11th: The wound in the trachea is quite closed by granulations, and the child constantly prattling in its natural tone of voice; the cough is scarcely troublesome, the secretions healthy, and rest undisturbed; with a good appetite, it is rapidly gaining lost flesh, and now walks and plays about the room.

We have been thus particular in recording the minutiae of this case to demonstrate—first, the urgent necessity for the operation; and second, the perplexities it may sometimes surround. But to demand for its confidence and popularity, requires the exercise of care in analyzing symptoms, comprehending the location of the obstruction, its true pathological cause, amount, extent, and the tendencies to death before the operation is demanded. Neglect of these precautions by "wise ignorance" has often brought true conservative surgery into disrepute, and the proclaimed necessity of this operation in disorders simulating inflammatory obstruction in the puerperal and hysterical condition (cases by no means uncommon and apt to alarm the inexperienced), has still further brought disavour upon it, and depressed the resources of science in public estimation.

#### OBSERVATIONS ON THE LATE EARTHQUAKE IN THE WEST OF ENGLAND.

By W. HAMILTON, M.B., Plymouth.

ONE of those phenomena, which are of rare occurrence, at least within the limits of authentic history, in England, and of which I am not aware that any former instance has been recorded in Plymouth, was experienced here between the hours of seven and eight, in the morning of the 12th of August last, when an earthquake of some seconds' duration was felt in the town and neighbourhood. The direction of the motion appears to have been from S.E. to N.W., and so was felt at Callington about eight o'clock. The shock then appears to have been of considerable violence, as it greatly alarmed the inhabitants, and led them to suppose that some magazine had exploded in their neighbourhood. At Beer, situated between this and Callington on the Devon side of the Tamar, the shock threw down a farmer's mill; and it was also felt at Plymstock, about two miles on the other side of Catwater, at Prince Town on Dartmoor, and at Liskeard in the West. At what other places it was felt I have not been able to learn. I have given a brief account of what I have been able to collect in my letter to the Registrar-General, who will, I hope, obtain more detailed and authentic information through the registrars of the district through which the convulsion was felt. The barometer, which has been low throughout the month, indicated a pressure of 29.57 inches

at eight on the morning of the earthquake; at the same hour on the preceding day it was 29.08, and the following day 29.84. Thunder storms took place on the nights of the 10th and 11th, and the atmosphere has been in a highly electrical state throughout the month. Plymouth and Devonport both stand on an argillaceous schist, and were on that account considered exempt from such visitations; but that prestige is now at an end. A similar prestige prevailed in Cumanà prior to the great catastrophe of 1797, and, singularly enough, from a similar cause, the peninsula of Araya being likewise seated on a schistose rock.

Humboldt remarks, at page 223 of the second volume of his Personal Narrative:—"If, in regions the most remote from each other, primitive, secondary, and volcanic rocks share equally in the convulsive movements of the globe, we cannot but admire also that, in ground of little extent, certain classes of rocks oppose themselves to the propagation of the shocks. At Cumanà, for instance, before the great catastrophe of 1797, the earthquakes were felt only along the southern and calcareous coast of the Gulf of Cariaco, as far as the town of this name; while in the peninsula of Araya, and at the village of Maniquarez, the ground did not partake of the same agitation. The inhabitants of this northern coast, which is composed of mica slate, built their huts on a motionless earth; a gulf of 3000 or 4000 toises in breadth separated them from a plain covered with ruins, and overturned by earthquakes. This security, founded on the experience of several ages, has vanished; and since the 14th of December, 1797, new communications appear to have been opened in the interior of the globe. At present, the peninsula of Araya is not merely subject to the agitation of the soil of Cumanà, the promontory of mica slate has become, in its turn, a particular centre of the movements. The earth is sometimes strongly shaken at the village of Maniquarez, when on the coast of Cumanà the inhabitants enjoy the most perfect tranquillity. The Gulf of Cariaco is, nevertheless, only sixty or eighty fathoms deep."

The phenomena of earthquakes are involved in much obscurity, but there seems in many cases, as, for instance, in that of the 12th of August, some connexion between it and the electrical state of the atmosphere. Electricity is necessarily developed in great quantity during volcanic eruptions, from causes which are tolerably well understood at the present day, but why an electrical state of the atmosphere should accompany the convulsion of an earthquake in regions remote from an active volcano, is a problem yet requiring solution.

The earthquake of the 12th of August was felt more extensively than I was at first aware, but I cannot obtain any reliable statements of the time at which it was felt at the different places, I cannot trace with anything like certainty the direction of the convulsion, but my impression is that it was from east to west. Its severity appears to have been greatest down in Cornwall, since at Liskeard an old wall was thrown down by it, the bells of a house in Menhenniot were set ringing, and at Great Caradon, and other mines, the workmen, imagining the roof of the mine was tumbling in, made a precipitate retreat to the upper world. Altogether, the shock appears to have been what brother Jonathan would term "pretty considerable."

Was this convulsion connected with any volcanic or other disturbance in any other quarter of the globe? as, for example, with the eruption of Etna, which took place on the 20th, about eight days later; and to what source are we to ascribe its having been felt by the inhabitants of these towns, and as far east at least as Plymstock, where it was distinctly felt by my daughter, Mrs. Harrison, and others, in the house of her father-in-law, for the first time in the records of authentic history. She describes it as a tremulous motion, accompanied by a low rumbling noise, resembling that occasioned by the passage of a heavily-laden waggon.

Are we to suppose it arose from some internal commotion of the globe, restricted to the portion immediately beneath

our western peninsula? or can its effects be traced in any line connecting the west of England with Italy and Sicily?

With the internal condition of our globe we have no prospect of ever becoming more than hypothetically acquainted, but there are strong grounds for believing that at the depth of a few miles beneath the solid crust on which we are placed, there exists a mass of molten matter which contributes to maintain the heat of the surface. It has been ascertained by experiments made in our deepest mines, that the temperature increases as we recede from the surface, and that this temperature at the several depths is permanent throughout the year, and at all hours of the day and night, and is wholly independent of the presence or absence of the workmen, or the number of lights employed; and Mr. Hearder mentioned to me the name of a mine, which I now forget, in which, at a considerable depth below the surface, in the course of the working, several jets of boiling sea-water burst out, the water of which in its chemical composition corresponded exactly with that of the sea, which appears to have penetrated through some unknown crevice and reached the heated surface beneath, and in this state was forced upwards by the hydrostatic pressure from behind. Humboldt conceives the interior of the globe to be cavernous, but such an idea is opposed to all that we know of the density of the earth and the laws of gravitation. It would be worth while to investigate, as far as our means will allow, the nature of the interior of our globe, availing ourselves of the deepest mines which have been sunk, one of which, in Cornwall, somewhat exceeds a mile in depth.

If a society could be organized to collect information from persons connected with the deepest mines, both in Great Britain and other parts of the world, it could not fail to add much to the existing stores of our knowledge. It is a remarkable fact, that most if not all of the known volcanoes in the world partake of an intermittent character. That of Morne Agarou, in the Island of St. Vincent, appears to have a period of about ninety-four years; and its next state of pyrexia may be looked for some time in the year 1906. The first eruption of which we have any authentic notice having occurred in 1718, and the second when I was at Nevis, on the 27th of April, commencing suddenly at noon, and not ending before the afternoon of the 1st of May. Dr. Anderson visited the crater on the 4th of March, 1784, after sixty-six years of repose, and found stronger symptoms of activity than were observed twenty-eight years later by a party who descended into the crater on the 26th of April, 1812, within twenty-four hours of its renewed activity. This eruption was the closing scene of a series of commotions which had kept the Azores, a large portion of North America and South America in a state of agitation for nearly two years. The great earthquake which destroyed the city of Caracas, preceded the eruption of Morne Agarou by only thirty-two days, and was clearly but a portion of one connected chain of phenomena. Whence arises this intermission, and this progressive march of agitation? Vesuvius re-awoke after a slumber of an unknown duration in the year 79; and Morne Pelee, in Martinique, like Vesuvius, on the 5th of August, 1850, both bearing unmistakable traces of former activity at some period beyond the limits of human records. Multitudes of similar instances might be adduced, and the whole subject is one of deep mystery, and still deeper importance to our well being.—*Phar. Jr.*

**A CASE OF CÆSARIAN SECTION.**—The Paris papers announce the unhappy termination of the case of Madame Francoise-République. It is well known that this formidable operation was performed on the 2nd December. When the circumstances attending it are considered, the result will not be a matter of surprise. The form and constitution of the patient were unfavourable, the fœtus was a monstrosity, and the barbarous instrument employed, the sabre. It is but a slender source of consolation to be informed that the infant has survived, and promises to be an emperor.—*Lancet.*

## HOMICIDAL MONOMANIA.

(Extract from an article in the *Journal of Psychological Medicine* of Dr. Forbes Winslow, for October.)

ONE of the most remarkable and interesting cases illustrating this form of insanity, homicidal mania without aberration of intellect, recently occurred at Lyons; the medico-psychological evidence has been collected and published, with observations by Artaud, whose work has suggested the previous observations. Anthony Emmanuel Jobard was born on the 4th of February, 1831, in the village of Essertenne, Haute Saône; his parents were respectable; and his mother and younger sister are described to have been very religious. The infancy of Jobard was passed at home, without the occurrence of any remarkable incident; at twelve years of age he was admitted to communion in the Catholic Church; and the priest of Essertenne declared that no child ever gave him greater satisfaction. His habits were regular, his disposition gentle, and he was very social and kind to his companions, with whom he was a great favourite. Having received his first communion, he attended mass regularly, assisted in the offices, and was punctual in the discharge of his religious duties; nevertheless, at this early period of life he addicted himself to a degrading and solitary vice. At thirteen years of age he left his native village, and with letters of introduction from his late pastor, he was sent, to complete his religious education, to M. D'Oigny, the canon of Dijon, and here remained at school for three years; leaving the house only to go to the lodgings at which he slept. Here also he is reported to have given his masters every satisfaction; but whatever may have been his exemplary conduct outwardly, at the expiration of this time—when, be it observed, he was only sixteen years of age,—in addition to the vice to which we have adverted, he began to frequent the society of disreputable women. His career of vice began therefore at a very early age, and causes were brought into operation which notoriously pervert the moral feelings, and undermine the strength of the intellect. We are no apologists for crime. The young Jobard had already entered the seductive labyrinth of temptation, and, doubtless, gave unbridled indulgence to his passions; albeit, in the presence of his preceptors he maintained the appearance of being a virtuous and well-conducted youth. The good canon at Dijon was already interested in his welfare; and being now sixteen years of age, and old enough to prepare himself for the active business of life, under his recommendation he was received as a clerk in the establishment of M. Thiebaut, a highly respectable clothier and draper at Dijon. This mercantile firm, which had been long established, bore a high character; the persons employed in it were boarded and lodged in the house, and their conduct, a matter of course, subjected to the general surveillance of the heads of the family, it being understood that any one who committed any infraction of the rules of religion and morality would be liable to summary dismissal. Upon these terms Jobard was admitted, and received, independent of his board and lodging, in the beginning 200 francs a year, which sum was gradually raised until it reached 450 francs. His conduct continued to all appearance good: he was kind, affectionate, and sober; fond of playing with the children of the family; and the care he took of a pet lamb obtained for him the title of "*Père nourricier de l'agneau*," a circumstance indicating elements and feelings of humanity which should not be lost sight of in the sequel. Here also he was constant and punctual in the discharge of his religious duties; he assisted in the service of the church on Sundays, attended the sermons which were delivered at Christmas, confessed and took the sacrament at Easter; all which, it is stated, he did without any apparent ostentation. There can be no doubt, however, that he still privately—when absent from the house of his employers—persisted in the same immoral habits, which he carried to an inordinate excess, and, at the same time, blended his misconduct with religious, or we should rather say, superstitious feelings, often reason-

ing upon scripture passages, and addressing exhortations of reformation to his reprobate companions. He would advise the very females with whom he associated to give up their vicious course of life, and on one occasion took very great pains and interest in endeavouring to recommend one of these unfortunate women to retire into a convent, and there expiate by penitence the errors of her past career. This may appear strange, but the contradictions in human nature are very marvellous. The notorious Burke, who was hanged for murder in Scotland, which he committed for the purpose of selling the remains of his unfortunate victims to the anatomical schools, was very partial and kind to children. He preached religious sermons, and the whole series of his murders was suggested by his confederate Hare reading aloud one winter evening the death of Benhadad by Hazael, in the second book of Kings.\* Incompatible as true religion must ever be with every description of crime, yet we frequently find the almost inarticulate voice of conscience reminding the worst natures of its mandates. Once deeply and at an early age implanted in the mind, true religious and moral principles cannot easily be uprooted, but spread like pure ore through a corrupt soil, blending with elements it fails to purify. We do not accuse such men of hypocrisy; they express in such moments feelings which have become a part of their moral constitution, and which can never be thoroughly eradicated.

These habits of criminal self-indulgence, commenced, as we have seen, so early in life, soon began to undermine the health of Jobard, whose nervous organization, while yet a youth, could not fail to become thereby enfeebled, and otherwise affected. The health and spirits he had enjoyed in the little village of Essertenne, soon failed him at Dijon; he suffered frequently from intense headache, attended with a sense of weight upon the brain, giddiness, and a general feeling of bewilderment; which distressing symptoms ended in a copious bleeding from the nose, which doubtless relieved the cerebral congestion. On one of these occasions the attack assumed a very alarming character, as may be inferred from the following account given by Dr. Noirot, a physician at Dijon, who, upon the occasion of the trial to which we must presently refer, made the following deposition, in the form of a certificate or affidavit. We translate it literally:—"I, the undersigned, Doctor of Medicine of the Faculty of Paris, certify as follows:—A few years ago, the precise date of which I can scarcely determine, but which, from different circumstances, I believe to have been in the winter of 1844-5, I was called one evening by Madame Perle, a "*sage femme*" at Dijon, to attend a young man who was lodging in her house, Ant. Em. Jobard. They informed me, upon visiting him, that he had for many days previously complained of severe headache, and that he became on that morning delirious. He was so when I saw him; and from this fact, the state of his pulse, and other symptoms, I apprehended inflammation of the membranes of the brain (*meningitis*). Accordingly I proposed that he should be immediately bled; he obstinately, however, resisted the operation, and I thereupon ordered the application of leeches, and then withdrew. The following morning, I found the application of the leeches had been neglected; but during the night a very copious nasal hæmorrhage had taken place, which salutary crisis cut

short the disease. He no longer complained of the sense of weight and pain in the head, accompanied by general weakness, which he had endured during the whole of the previous week. I heard no more of the patient, and lost sight of him up to the present period. (Signed) L. Noirot, D.M.P.; and dated Dijon, 7th November, 1851."

On Sunday, the 14th of September, he attended mass, and afterwards vespers, as usual, and after the latter service, went to a restaurant's with three of his fellow-clerks, belonging to M. Thiebaut's establishment, and there they dined together very cheerfully, nor did either of them drink to excess. When the dinner was over, Jobard suddenly rose from the table, and left his companions, following hurriedly into the street a German singing girl, with whom it appears he went home. He remained with her about ten minutes, and then returned to the café, when he called for a glass of *kirsh*; his expression of countenance was anxious and haggard, and the waiter noticed that he was much agitated. Immediately afterwards he took up his cane and hat, and without saying a word to his companions, who were still at the table, he again sallied out, and went in search of a cutler's shop, for the purpose of purchasing a knife; but it was after nine o'clock, and the shops were then shut. Foiled in this intention, he directed his steps to a house of ill fame in the Rue Quentin, where he passed the night. His conduct there, which we abstain from describing, was exceedingly extravagant—apparently insane. About two o'clock in the morning, he hastily dressed himself, said he must be off by the railway to Paris, and, without uttering a word, left the house; and without being prepared for the journey, proceeded to the railway station, and asked for the first train to Paris. He was informed it would not be there until seven o'clock. The train, however, for Châlon, came up while he was talking, and he instantly took his ticket, and proceeded *en route* for Lyons. Arrived at Châlon, he took an omnibus which conveyed passengers to the steam-boat which leaves the pier for Lyons. We must now premise that we are tracking the steps of an assassin—the question of homicidal monomania will be presently considered. In the train from Dijon to Châlon, he tells us that he could not explain the nature of his feelings; he could not think or reflect on anything—(*j'avais la tête vide*); he ate a little, however, on the way. Arrived at Lyons, he felt much fatigued, and walked mechanically to a restaurateur's, where he dined. He drank half a bottle of wine, but ate very little. During dinner, he asked the waiter to direct him to a cutler's. The man did so, but Jobard could not find the house; he therefore got into a cabriolet, and desired to be driven to a shop where they sold knives, where he bought a knife, with as much coolness as if it had been a lead pencil, or any other harmless article. This done, he sought out and entered another house of ill fame in the Rue de la Cage, determined, he afterwards stated, to kill one of the female inmates. He was introduced to a girl named Rachel; he remained with her half an hour, but she was so pretty that his arm was arrested—he could not strike the blow—and was tempted to delay for a few hours his resolution; he therefore left her, promising to return to her at night after the theatre, and he adds, that if he had done so, he would have stabbed her in her sleep (*je lui aurais percé le cœur pendant son sommeil*.) This resolution, he confesses, he did not take without some qualms of apprehension, for he was afraid that before he could effect his escape he would be torn to pieces by the exasperated women of the house.

This happened on Monday, the 15th of September, 1851. Upon arriving in the town, he stopped as he walked along the streets to read a bill of the play, and he determined to go to the Théâtre des Celestins. Upon leaving this house, therefore, after walking for about ten minutes in the Jardin des Plantes, he went to a café opposite the theatre, and there waited until the doors opened. He then paid for his admission, and took his seat in the gallery, *aux premières*, but at the end of the first act of the second piece, which was entitled *Adrienne Lecouvreur*, he changed his place, and went into the amphitheatre, where he sat

\* This is a very curious fact. The diabolical suggestion arose from Hare reading the account given (verse 15, chap. viii.) of the death of Benhadad, who was thus killed by Hazael: "And it came to pass on the morrow, that he took a thick cloth, and dipped it in water, and spread it on his face, so that he died." Burke and Hare adopted the same plan. They made their victims drunk, and then covered the mouth and nostrils with wet cloths. Sometimes, by kneeling on the epigastrium, they forced a deep expiration, which emptied the lungs, and the wet cloths prevented the readmission of the air. This murderous method was so physiologically scientific, that it was suspected to have been suggested by some anatomist. This was not true: the above statement came out in evidence.

down behind a pillar. He there saw at a little distance from him a little girl about ten years of age; he grasped his knife, and would have killed her, but she was beyond his reach, and he could not move towards her without attracting attention. Another little girl, apparently between twelve and fifteen, sat nearer and a little to his right, but she too was beyond his grasp. His attention was next directed to a lady who sat immediately before him; she wore a gray silk dress, and as he stood up and looked down upon her, he saw a portion of her breast uncovered; but at this moment he heard steps behind him, and looking round saw the manager of the theatre, whom he knew personally, and who had just entered the house by a door near him. He instantly pretended to be cleaning the nails of his fingers with the knife; turning towards him, he smiled, and after exchanging a few gracious words with each other, the manager passed on. Suddenly, a scream, sharp and piercing, resounded through the house, and persons were seen rising confusedly around the place whence it proceeded. The fatal deed was perpetrated. With deadly aim and force, he had plunged the knife into the bosom of the unfortunate lady, and as she uttered that thrilling shriek, she withdrew with her own hand the knife from the wound, and, covered with blood, fainted in the arms of the persons near her. Her husband, who was sitting next her, not having any idea of the fatality of the blow, turned round upon the assassin, and exclaimed, "What have we done to you, that you should thus strike my wife?" "Nothing!" answered the imperturbable Jobard; "you have done nothing!" He stood calmly with his arms crossed upon his breast, and added—"I am a miserable being; do what you please with me; it is not my wish to escape!" He was immediately arrested; he did not make the slightest resistance, and as he was being conducted to the Hôtel de Ville, he said, "I am well content." In the meantime, the poor lady was removed into the "foyer" (the green-room of the theatre); the wound now appeared evidently mortal, and in about five minutes she expired. She was a young woman, the daughter of M. Chabert, the *Proviseur* of the Lyceum at Limoges, and the wife of M. Ricard, the Professor of Mathematics in the same institution. Melancholy to add, she was in the family-way. As he struck her from behind, she never even saw the person of her murderer.

He was conducted a prisoner to the Hôtel de Ville, and placed in one of the dungeons, where his first care was to take the sleeves off his paletot, to prevent them being soiled, and then he fell on his knees in prayer. He conducted himself during his examination before the "Juge d'Instruction" with great calmness; his countenance maintained its usual expression, and his pulse was regular, and between 65 and 70 in the minute. When informed of the death of Madame Ricard, he said, "Dead, is she?—so much the better; since I wish them to put me to death." He then asked if there had been time for her to see a priest before dying, and upon being answered in the affirmative, and informed that he had prayed for her, he expressed his satisfaction, and added, "I am sorry I was obliged to put her to death; I pity her and her family, and in that sense I regret it; I shall repent before God; as for me, I cannot make myself better understood than by saying,—I regret nothing." In his first examinations he persisted in the same tone, confessing but not regretting the act; on the contrary, he said, "I always knew, even when I contemplated it, that it was a crime for which I was responsible before God and man." He confesses, "I bought the knife as coolly as I would a crayon, or anything else. I struck her as I would have done a block of wood." At another time he said, "I committed it without reflection. If I had reflected properly—if I had confided in any one—if they had made me reflect upon it—I should have desisted." The murderous weapon was produced before him; he looked upon it with indifference. The distressed husband was confronted with him, and he evinced very great emotion. He was then conducted into the presence of the dead body, and when he beheld his victim, he ap-

peared on a sudden horrified, became extremely agitated, and his pulse rose, gave 88 pulsations in the minute, and was thready and intermitting. He appeared unable to support himself, but nevertheless he almost immediately recovered his self-possession, and spoke with his usual calmness. Upon leaving the room, he again appeared much affected; bewailed the fate of his victim, and the distress of her family; but for himself, he again added, "*I regret nothing.*" The following day he was again examined at the Palais de Justice, and now, he altogether altered his tone; "If my time," he exclaimed, "were this day to come over again, I would not commit the deed I have done: yesterday I endeavoured to render my condemnation inevitable;—to-day I would desire to live." Since his imprisonment, it should be observed that he had experienced nasal hæmorrhages, which may have relieved the brain, and conducted to the return of a more natural state of feeling.

Immediately after the crime was committed—within a few hours—the medico-legal question arose as to the condition of his mind: When he perpetrated the act, was he sane or insane? An ordonnance was issued immediately by the Juge d'Instruction, requiring Dr. Magaud to examine and report upon his physical and moral state; and Messrs. Tavernier and Gromier, physicians frequently called upon to give medico-psychological evidence before the criminal tribunals, received the same mission. The conclusions arrived at by Dr. Magaud were, that the act was premeditated; the motive alleged in his declaration was insufficient to prove any aberration of the intellectual faculties; that there was a continual conflict between his religious ideas and sensual instincts, which may in some degree have obscured his understanding; but that his sense of moral responsibility, although enfeebled, was nevertheless not destroyed, therefore the evidence was not sufficient to be placed in justification of the crime, although it might be urged in mitigation of the punishment. The report of Drs. Tavernier and Gromier, in which they also recapitulate all the circumstances of the case, terminated in opposite conclusions. First, they were of opinion that at the moment Jobard committed the act he was in a state of dementia; second, that Jobard could not be considered responsible for an act which he committed without the participation of his will; third, that as his description of insanity leads to disastrous consequences, society should exercise its right of placing Jobard in a situation to prevent him committing any other outrage, and that he should be confined for life in a lunatic asylum.

The result, therefore, or rather the opinions expressed in both of these reports, are thus far approximative; the one recognizes enfeeblement, the other derangement of the moral sense. The one pleads for mitigation of punishment, the other recommends deprivation of liberty, and confinement, for life, in a lunatic asylum. The view taken by Dr. Arthaud, who has been at the pains of collecting the whole evidence in a very circumstantial manner—not, indeed, omitting the most trivial circumstances that could be interpreted in his favour, is, that Jobard, when he committed the act, was insane—and that his insanity was characterized by a general disturbance of the intellectual faculties; in support of which opinion he refers to the fact, that insanity in different forms, had declared itself both on the paternal and maternal side of his family. His grandfather, at the age of fifty or sixty, upon the loss of an action at law, was for several months insane. His disease assumed the form of lypemania. He continually cried "I am a lost man," believing he was about to be arrested; at length, after obstinately refusing food for a fortnight, he died of inanition. His grandfather's brother also died in a melancholic state, and the cases were very analogous. His cousin, Rosalie Jobard, when twenty years of age had an attack of acute mania. She was confined in the lunatic asylum of Maréville between two and three years, when she was discharged cured. On the maternal side, one uncle became insane at an advanced age, exhibited symptoms of lypemania, and died of senile dementia. Another was affected by melancholia, would associate with no one,

ate the roots of vegetables as he pulled them out of the ground, and wild fruits, and threatened to injure those who approached him. Another uncle, in a state of ordinary insanity, was confined in the lunatic asylum at Besancon, where he died. Again, one cousin was an epileptic and another imbecile from birth. Dr. Arthaud traces these, and some other examples in the family of Jobard of mania, lypemania, dementia, epileptic mania, and idiocy. It is impossible, he then adds, that the hereditary transmission of insanity can be doubted. Pinel, Esquirol, Marc, Falret, Descuret, Baillarger, Moreau, and all modern writers on insanity, consider hereditary transmission one of the most ordinary predisposing causes of this malady.

On the 23rd of March, 1852, Jobard was arraigned before the Assize Court of the department of the Rhone for the murder of Madame Ricard. Upon examining the body it was found that the knife had penetrated between the second and third ribs of the left side, traversed the anterior part of the corresponding lung, and, piercing the left ventricle of the heart, the point of the weapon terminated in the interventricular wall of the right ventricle. The facts of the case were too evident and incontestable to admit of any doubt, therefore the medico-legal depositions, which were endorsed on the back of the indictment, respecting the state of the prisoner's mind, constituted the principal evidence. During the trial the prisoner maintained his self-possession, but was manifestly anxious respecting its result, and endeavoured, by the answers he gave to the interrogatories put to him, particularly to remove the idea that the act was premeditated. He was ably defended by M. Dubost, his advocate; and after the President of the Court had carefully summed up the evidence, Antony Emmanuel Jobard was declared guilty of having voluntarily, and with premeditation, committed a homicide on the person of Josephine Annais Chabert, the wife of Ricard, whereupon he was condemned to hard labour for life.

We do not impugn the justice of this verdict, or consider that it was an aggravated sentence; because the homicidal act was clearly neither instinctive nor impulsive, but the result of premeditation and prearrangement, although the particular victim had not been selected for the assassination until a few instants before the act was committed. Furthermore, we fully admit that Jobard was morally insane; but there was not such an amount of intellectual aberration as to obscure or pervert the understanding; on the contrary, he himself acknowledged that he was conscious he was about to perpetrate a crime, and he knew that he would be responsible for the deed before both God and man. Hence we recognize—in the derangement of his moral or affective faculties and propensities only—extenuating circumstances which very properly suggested to the jury the recommendation to mercy; but we do not see sufficient evidence to justify the full exculpatory plea of insanity. There can be no doubt that a person so dangerous ought to be deprived of his liberty, and provided the hard labour which he is condemned to perform be not incompatible with health, or likely to shorten the duration of his life, we would raise no objection also to this part of the sentence. Indeed, we often in visiting the criminal wards of Bethlem, St. Luke's, and some of our public county asylums, have been struck at observing so many strong and healthy-looking criminal lunatics sauntering with their hands in their pockets, idly about the corridors and courts of the building. How much better would it be for these men to be obliged to work at some compulsory labour—some occupation adapted to their particular capacities and previous conditions in life. Assuredly, it would be beneficial to their bodily and mental state, and conduce materially to their recovery; for whether they are destined to remain under surveillance, or not, their restoration to sanity is to themselves, and all around them, of equal importance. The man who may, under some delusion consequent upon cerebral disease, has attempted even the life of his sovereign, may recover his reasoning powers, and it is manifestly important that he should do so before his death; wherefore he is entitled to

receive as much care and attention as any other patient who, upon recovery, becomes entitled to his liberty.

The present number of this valuable journal contains the following articles:—

Homicidal Monomania; German Psychology; Statistics of Crime, and the Moral and Mental Condition of Prisoners; The Law of Lunacy in France; Mental Dynamics, in relation to the Science of Medicine; American Institutions for the Insane; Mortality and Insanity in Separate Plan Prisons in England and America; On the Organization of Asylums for the Insane; Crime and Punishment in the United States; Education of Criminal Children; Legal Cases in Lunacy; Bethlem Hospital; Descartes; Miscellaneous Notices; Psychological Appointments; British Lunatic Asylums.

To CORRESPONDENTS.—“A Constant Reader” in our next. The hint respecting a review shall have attention; we know the party well. Some letters unanswered remain for private notice.

## MEDICAL PRESS.

“SALUS POPULI SUPREMA LEX.”

DUBLIN: WEDNESDAY, NOVEMBER 17, 1852.

### OPERATION OF THE DISPENSARY ACT.

PARLIAMENT has met, and now is the time to consider whether or not an appeal to it is desirable respecting the working of this measure; to consider whether the Act is in fault, or those who execute it. Away with retrospects and repinings, with grumblings and reproaches, with declamation and agitation, and let the truth come out. Every tangible defect must be pointed out, and every real grievance exposed, without colouring or exaggeration. Facts are still wanted, and until they are supplied no course can with safety be indicated. For example, we hear a great deal about the excessive dimensions of districts: does this misapplication of the powers of the Act exist, and if so, to what extent? A few cases of such abuse will not serve to move the government or legislature: there must be enough to provoke interference. At the moment we write, all the information required on the subject must be in black and white in the Poor-law Office, ready for production to Parliament; and if found sufficient to warrant it, a remedy must at once be provided for such a serious defect. If excessive size of districts be adopted by Guardians and sanctioned by the Commissioners, without remedy in any other place, a case for parliamentary interference arises: a clause in an amendment act must provide that no district shall in any case exceed specified limits. Then as to salaries. Will Parliament interfere after so lately leaving the arrangement of them to the Guardians and Commissioners? and if not, where lies the remedy when they are inadequate? We cannot suppose that the Commissioners will refuse to sanction a just remuneration to the Surgeon for his services, if the Ratepayers and Guardians assign it; and we believe they have not done so in any case, however backward they may have been in enforcing such compliance with the spirit of the Act. If, however, it can be made to appear that in a great number of cases both Guardians and Commissioners refuse to provide adequate salaries, a clause in an amendment act must declare the amount to be paid, notwithstanding the difficulty of laying down a maximum or minimum; for it is obvious that all cases are not alike. But our belief is, that the cure for this evil lies with those

who suffer from it, and that it is to be effected through the instrumentality of the Ratepayers, Guardians, and Committees, by patience, perseverance, and judicious management. If the Surgeon satisfies both rich and poor by the successful discharge of his duties, he cannot fail to exercise his share of influence in his sphere of operation, and thereby to secure his rights as other people do. The administration of medical relief to persons not entitled to it, is another of the difficulties of this measure which further legislation cannot well remove. In the present state of Ireland, and perhaps in other places besides Ireland, no law can draw a distinct line of demarcation between poor man and pauper; but in practice such a law can be enforced, under present provisions, by a fair consideration of the matter by all parties. Our object in making these few observations on this most important subject, at the present moment, is to remind our brethren in the provinces of their present condition as regards this subject, with a view to a candid and impartial consideration of it. They have now before them the results of recent legislation; and from their experience of the past, they can form some judgment as to the future, should they rely on the same means. When abuses multiply and difficulties increase, people say that "something should be done;" but speedily they find that it is not so easy to say what that something should be. Petition Parliament says one, frame an amendment bill says another, and ask for a select committee says a third. Any or all of these may be done; but before doing so, the complaint and prayer of the petition must be agreed upon, the clauses of the bill must be well considered, and the evidence to be offered to a select committee must be properly selected and arranged. If we are going to do anything of this kind let us do it with as little talk about the matter as possible.

#### THE CASE OF BOURN v. COX.

It is only fair to allow the defendant in this case to have the benefit of his own version of it, and we therefore print the following note, addressed to the Editor of the *Lancet*. As we have already stated, we noticed the matter because of its importance as an exemplification of the working of the English system. We do not, however, pretend to claim for Ireland an exemption from such occurrences. A few years ago we had to publish a case of somewhat similar nature which took place in Dublin, and in which a "General Practitioner" was not the only actor.

On what do you found the so-called "facts" given by you in your comments on the case Bourn v. Cox? Your statement of facts is an almost verbatim copy of the opening address of Mrs. Bourn's counsel, which contains statements which were on the trial totally disproved. The fact that a bill of £2 3s. 6d., or any bill at all, was delivered to Bourn, was entirely rebutted. It was not a fact that the ship was to sail on the Tuesday following the arrest on the Saturday, but was to have sailed that very day. It is not a fact that the judge remarked that a gross fraud had been committed. I have already answered the charges against me in the *Provincial Medical and Surgical Journal*, and also before the Bath and Bristol Branch of the Provincial Medical and Surgical Association. I am quite sure, if you knew the means now, and for some time past, in operation here to damage one who has always endeavoured to conduct himself honourably and respectfully as a member of an honourable profession, you would not lend your columns to such a purpose. The whole subject is now under consideration by the District Council of the Bath and Bristol Branch of the Provincial Medical and Surgical Association, and I do not fear being able to show that I have acted neither dishonourably nor unprofessionally.

#### VULGARIZATION OF "EM DEE."

THE following, which elicited certain objurgations, published in our Number of the 3rd of November, was accidentally omitted. We now insert it by way of explanation:—

I am a physician, well stricken in years, and cannot fail, as must every careful observer, to notice the gradual declension of the medical profession in social estimation and position. Reflecting on what can be the cause of this, I have come to the conclusion that the most potent is the vulgarization of the title of M.D. When I commenced practice, the physician was always regarded as a gentleman, and met with the consideration due to a gentleman in society, and the degree of M.D. was then respected as indicative of the man of polite education, as well as of superior professional attainments. He was, in fact, the connecting link between the profession and the aristocracy, of birth and talent, and it was due to the status of the pure physician that the profession of physic was ever regarded as a polite calling rather than a trade. Now how changed is the state of things! So far from now representing the man of university education and prolonged professional study, it is assumed by every fresh emancipated from the rolling of pills and mixing of potions, and is paraded by men who draw teeth for a shilling, and "vaccinate gratis." Can it be a matter of surprise that when Dr. A is seen tugging at an obstinate upper molar, and even eclipses his opposite neighbour the chemist in the blue and red glories of his shop window, that the title should sink in public estimation. How deplorably it has been lowered by such doings, can only be appreciated by those who, like myself, have passed the meridian of life. Why, my grocer, who stands hat in hand in my hall for orders, had two of these bastard M.D.'s at a tea-party last night. There seems to be a morbid desire among general practitioners just now to dub themselves M.D. A highly respectable gentleman of this class in my town has not long since thus added to his title. If he hopes to add to his position by so doing, how will he be mistaken! Still acting as an apothecary and union doctor, however, his brass plate of "Dr. —, Surgeon-Apothecary," may astonish the clodpoles from his parishes, it will give him no importance in the eyes of the more intelligent. By thus decorating himself, the practitioner in pharmacy may degrade the status of the true physician, but he will not raise his own.—*Letter in Lancet.*

#### UNIVERSITY OF ST. ANDREW'S.

LIST of gentlemen who had the Degree of Doctor of Medicine conferred upon them, October 22, 1852:—Thomas Allen, M.R.C.S. and L.A.C., London; S. Blackmore, M.R.C.S. and L.A.C., London; Leonard Buckell, M.R.C.S. and L.A.C., Chichester; Gustavus Matthews Burton, M.R.C.S., Lancashire; John Cautley, M.R.C.S. and L.A.C., Yorkshire; Maurice Davis, M.R.C.S. and L.A.C., King's College, London; Joseph Meldon Dempsey, L.A.C., London; James W. Duffy, M.R.C.S., Chili, South America; Charles Anthony Floyer, M.R.C.S. and L.A.C., Camberwell, Surrey; George Fayer, M.R.C.S. and L.A.C., Essex; Robert Anstruther Goodair, Fifehire; Richard Hassall, M.R.C.S. and L.A.C., Extra-Licentiate of the College of Physicians, Surrey; A. Newstead Holmes, M.R.C.S. and L.A.C., Yorkshire; Fred. Lewins, M.R.C.S. Ed., Bervie, Kincardineshire; Frederick John Lowes, M.R.C.S. and L.A.C., Gosport; Francis Notridge Macnamara, M.R.C.S., King's College, London; Albert Massey, M.R.C.S. and L.A.C., Camberwell, Surrey; Wm. O'Connor, M.R.C.S. and L.A.C., London; Patrick Panton, M.R.C.S. and Extra-Licentiate of the College of Physicians, Turriff, N.B.; John Dugale F. Parsons, M.R.C.S. and L.A.C., Gloucestershire; J. Henry Shorthouse, M.R.C.S. and L.A.C., Surrey; Charles Taylor, M.R.C.S. and L.A.C., Damberwell, Surrey; Charles Jean Tourrelle, M.R.C.S., Mauritius; John Turnbull, M.R.C.S., East Lothian; Henry Watts, L.A.C., Staffordshire; Wm. Wightman, M.R.C.S. and L.A.C., Yorkshire; Simon Armstrong Willis, Licentiate of the Faculty of Physicians and Surgeons, Glasgow, Fermanagh, Ireland.

Mr. Joseph Ewart of Guy's Hospital, passed the requisite examinations, but in consequence of an informality in his certificates, his degree was temporarily deferred.

JAMES McBEAN, A.M., Secretary.

## CORRESPONDENCE.

## MEDICAL CHARITIES ACT.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—On looking over your very useful Students' Number for this year, I find you have omitted the Regulations of the Poor-law Board. You are aware, on the appointment of our learned Commissioner, he "made a rule" that he would not sanction the appointment of a medical officer to any of the lucrative posts under his command unless he was possessed of a surgical diploma from one of the usual licensing bodies in the united kingdom. I will feel much obliged if you will inform me, whether the Commissioners, when they depart from this rule, and confirm the appointment of a man not a surgeon, confer on him ("by the power in them vested") a surgical diploma; or if they merely break through their own rule with their "*sic volo sic jubeo*."

When you have kindly answered this query, and informed me of the manner in which the Poor-law Board manufactures a surgeon, I will, in return, explain to you the manner in which they dismiss a surgeon in possession, and under circumstances that will, I think, startle "One of the late County Secretaries" and the principal agitators who stipulated (as represented in his letter) for the preservation of *existing rights*, will produce a feeling of *insecurity* among all, particularly among those holding the double appointment of a poorhouse and dispensary; and will, I promise you, in its tyranny, treachery, and corruption, throw completely into the shade the grievances inflicted by permission of the act; aye, and the outrages perpetrated in *defiance* of the act, as described to you in my former letters.—Yours truly,

Nov. 11, 1852.

A FELLOW OF THE COLLEGE.

We know not what the case may be to which our correspondent alludes; but this we know, that the dabbling of public departments in the troubled waters of medical affairs is a most dangerous experiment. For the Crown or Parliament to erect institutions for the licensing of Physicians and Surgeons, and then to find these institutions over-ridden by Poor-law Boards and Army Medical Boards is astounding. Yet such is the present state of affairs.

## PRIZE ESSAY ON CHINA.

Two premiums of £50 each, for essays on China and the Eastern Archipelago, in connexion with the objects of the great Exhibition, offered by Mr. W. P. Hammond of London. The following gentlemen will act as judges of the merits of the essays:—The Right Honourable the Earl of Shaftesbury, P.C.; Thomas Baring, Esq., M.P., London; William Brown, Esq., M.P., Liverpool; James Pilkington, Esq., M.P., Blackburn; Thomas Bazley, Esq., Manchester.

£50 for the best essay on China, embracing the following points:—The capabilities of that empire to consume the manufactures of Britain, and existing impediments thereto; the effect of the present British tea duties on its consumption, and on the China trade generally, and the probable influence thereon of a reduction of duty; the opium trade, and its effect upon the commerce and morals of China and India; general remarks on the empire of Japan, and prospects of trade therewith; suggestions as to the most efficient mode of extending Christianity in China.

£50 for the best essay on the Eastern Archipelago, including the Philippines and the Gulf of Siam, embracing the following points:—Piracy, its extent and effect on the price of Straits produce and the consumption of British manufactures; the best means of suppression or prevention; the commercial capabilities of the countries alluded to, and existing impediments to their expansion; Christianity, the best means of its extension therein.

The object of Mr. Hammond in offering these premiums is

to promote the interests of religion and commerce in the China seas and Eastern Archipelago, in connexion with the design of the great Exhibition; he proposes that the rewards should be given in cash, or in gold medals of equal value, at the option of the successful competitors. Three or more competent and disinterested judges are to be appointed to decide upon the merits of the essays, and the last day of October, 1852, is fixed upon as the limit within which manuscripts must be sent in. [At the request of several parties, and to give an opportunity for the transmission of information relative to the empire of Japan which may be obtained by the expedition recently despatched by the American government, this limit is now extended to the last day of April, 1853.]

It is further proposed that a selection of the manuscripts be made, and the copyright of them to be disposed of, and published with the name of each essayist attached, and the net proceeds rateably allotted to the writers, or, with their consent, disposed of as may be considered by the judges most likely to promote the objects treated on; and it is particularly requested that such consent to the publication, and option as to the disposal of the proceeds, be forwarded by each party; but in the absence thereof, assent will be understood and acted upon.

In forwarding each manuscript, it would be preferred that a sealed envelope accompany it, containing the name of the contributor, and superscribed with a motto—the same motto being placed at the head of the essay. The envelope will then not be opened, and consequently the names of the successful parties not be known until after the awards by the judges. This course will not be necessary in the case of short manuscripts contributed for information, and not intended for competition.

In selecting from the contributions those manuscripts which it is proposed to publish, it is intended to include all those containing valuable information, though not sufficiently complete or copious to entitle them to a prospect of the premiums; hence, any member of the mercantile community, willing to convey his practical opinions, and the result of his experience, in connexion with the subjects to be discussed, will be offered a convenient opportunity of laying before the public such details. The contribution, also, on the part of persons in official positions, of statistical tables, and other similar information they may be in a position to afford, will materially aid in rendering the proposed volumes more complete.

In selecting the gentlemen named as judges, to whose kind and most valuable co-operation the success of the proposal will be mainly due, it has been thought desirable not to include parties directly engaged in the commerce of the China seas, with the view of ensuring the fullest confidence in the strict impartiality of the awards, and the avoidance of any possible bias in considering the merits of any question discussed, upon which difference of opinion may exist; the main object being to collect a body of evidence bearing on the present state of religion and commerce in the important countries encircling the China seas, furnished chiefly by parties possessing practical experience on the subject—difference of opinion, of course, in a sound direction, being freely permitted; and the *pro* and *con* of each question being thus fairly brought together.

It is scarcely necessary to add, that the high standing of the gentlemen acting as judges affords the best possible guarantee to essayists. The essays to be restricted to no particular length or character, and the awards to be based on general merit. The second and third, each, to receive a silver medal. All letters and manuscripts must be post-paid, or where pre-payment cannot be effected, a reference for payment of the postage in London will be required. The serious addition which would otherwise be made by foreign postages to the sum offered as premiums, renders obvious, it is hoped, the necessity of this arrangement. In the possible event of none of the essays being deemed by the judges to possess sufficient merit, they reserve to themselves the right to postpone the awards.

The importance of the subjects embraced will be apparent from the following facts:—The population of the countries alluded to may be estimated at more than four hundred millions; any suggestions, therefore, which may tend to promote Christianity and extend civilization and commerce amongst nations now immersed in barbarism and idolatry, and numbering nearly one-half of the whole human family, cannot but be valuable. The important subject of the tea duties, and their effect on Anglo-Chinese commerce, may be

expected to elicit numerous useful facts and suggestions. The opium trade, especially in connexion with the expiration of the East India Company's Charter in 1854, and its effect on the trade, currency, and morals of China. The collection of information on the sealed empire of Japan, and the causes of the singular fact that British relations therein were more developed two hundred years ago than at present. The serious subject of piracy in the China seas, and also in the Eastern Archipelago. The inland restrictions placed on the transit and distribution of British manufactures in China, and other impediments to the development of trade, and the employment of shipping in the China seas. Observations on the present state of British commerce in Java and the Philippines, and suggestions for the removal of any existing restrictions thereon. The state of Christian missions in China and the Eastern Archipelago, and the probability of practical suggestions for their improvement and extension.

These are questions equally interesting to the merchant, the philanthropist, and the Christian in all parts of the globe; and it is hoped that all persons possessing the required opportunity and information will contribute an essay, which may be sent either direct to Messrs. W. P. Hammond and Co., London, or, if preferred, to the care of either of the judges.

M. W. HANLON, M.B.

### SURGICAL SOCIETY OF IRELAND.

The First Meeting of the Society for the Session 1852-3 will be held on Saturday Evening, the 20th inst., at the Royal College of Surgeons, at Half-past Eight o'clock p.m.

The President of the College in the chair.

CHARLES BENSON, } Secretaries.  
O'B. BELLINGHAM, }

### MEDICAL ESTABLISHMENT.

WANTED to take charge of a Medical Establishment in the North of Ireland, a Person possessing a Legal Qualification (a Protestant).

After three or six months, the Proprietorship may be obtained on equitable terms.

Apply at this Office.

### BARON LIEBIG ON PALE ALES.

If I wished to associate with any individual brewery my remarks on the alleged adulteration of bitter beer with strychnine, it would have been only natural to have mentioned another brewery, in which alone, and not in Mr. Allsopp's, I was engaged in investigating the Burton mode of brewing, and it was also in that brewery, and not in Mr. Allsopp's, that the Bavarian brewers acquired all the instructions they obtained—at Burton. The admiration I expressed of this beverage, in my letter to Mr. Allsopp, is advertised in such a manner as to lead to the inference that my praise was exclusively confined to Mr. Allsopp's beer; this was not the case; my remarks referred to that CLASS of beer.

JUSTUS LIEBIG.

Giessen, July 24, 1852.

N.B. The Baron's original letter is in the hands of Mr. Miller, at the Jerusalem Coffee-house, Cornhill, where it may be seen by any one taking an interest in the matter.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Cozeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

### THE COMPOUNDING DEPARTMENT AT G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

### HOSPITAL SULPHATE OF QUININE, PURE CRYSTALLIZED.

Prepared by EDWARD HERRING, of the late firm of HERRING, Brothers, for the use of Hospitals, Dispensaries, &c.

THIS Sulphate of Quinine is chemically pure, its form of crystal is the same and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is unbleached and the other bleached. It was originally introduced for the use of Hospitals, Dispensaries, and public Charities, but its purity and great reduction in price is attracting the attention of Medical Men and the Dispensing Chemists.

It is put up in bottles (free) of three ounces and six ounces each, capsuled, with the name of the Proprietor, and labelled with the name of the Inventor. The peculiar mode of preparing the unbleached and white sulphates is being made the subject of a patent, and will shortly be made public.

Both articles to be had of the leading Druggists in London and the united kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.

October 23, 1852.

### SHIRTS CUT BY MACHINERY.

#### WEBB AND CO.'S

New System of Shirt-cutting by Machinery enables them to produce really First-class Shirts at prices lower than they have ever yet been offered.

Their Eglinton Shirts,

at 2s. 6d., 3s. 6d., and 4s. 6d. each,

are accurately Cut, elegant in Design, and perfectly sound in Fabric.

A large assortment of Fancy Veined Full-dress Shirts always on hand.

### THE TAILORING AND GENERAL OUTFITTING WAREROOMS

are now most extensively supplied with every description of WINTER CLOTHING.

### THE READY-MADE DEPARTMENT contains an immense variety of

Top Coats, Travelling Coats, Wrapper Coats, Pilot and Frieze Pea Coats,

at 15s., 17s. 6d., and 20s. each,

which, for Workmanship and Solid Value, are not and cannot be surpassed.

WEBB AND CO.,

10, 11, and 12, CORN-MARKET.

## SCHOOL OF SURGERY.

## ROYAL COLLEGE OF SURGEONS IN IRELAND.

WINTER SESSION 1852-53.

The Dissecting-rooms opened on the 1st of October, and the Lectures commenced on the 25th.

Anatomy and Physiology—Dr. Jacob.  
 Descriptive Anatomy—Dr. Hart and Dr. Power.  
 Surgery—Mr. Porter and Mr. Hargrave.  
 Practice of Medicine—Dr. Benson.  
 Chemistry—Dr. Barker.  
 Midwifery—Dr. Beatty.  
 Comparative Anatomy—Dr. Jacob.  
 Dissections by the Professors of Anatomy and the Demonstrators—Dr. Leeson, Mr. T. D. Hargrave, Mr. Malcomson, and Mr. J. Morgan.

## SUMMER SESSION.

Materia Medica—Mr. Williams.  
 Medical Jurisprudence—Dr. Geoghegan.  
 Botany—Dr. A. Mitchell.  
 Practical Chemistry—Dr. Barker.

The fee for each of the above Courses is two guineas, except Comparative Anatomy, which is free.

A public course of lectures on Comparative Anatomy and Zoology, free to all students, is delivered by the Professor of Anatomy and Physiology at the commencement of the session, and additional lectures on the same subject at intervals during the winter.

Practical instruction in Operative Surgery is given by the Professors of Surgery, separate from the surgical lectures. Fee, £5 5s.

The Professor of Chemistry receives operating pupils into the Chemical Laboratory.

The following Ordinance was made by the Council of the College on the 9th of April, 1851:—"To enable surgical students to devote more time to hospital attendance and dissections during the winter session, the lectures on materia medica, medical jurisprudence, practical chemistry, and botany, shall be delivered during the summer session in the school of the College, and in the schools recognized by the College; and certificates granted subsequent to the 30th of April, 1851, shall not be received as a qualification for Letters Testimonial, unless issued in conformity with this regulation." Similar regulations have been adopted by the Council of the College of Surgeons of England.

## Hours of Lecture :

Descriptive Anatomy—Twelve o'clock every day.  
 Chemistry—One o'clock, Mondays, Wednesdays, and Fridays.

Anatomy and Physiology—Two o'clock every day, except Monday.

Surgery—Three o'clock, Tuesdays, Thursdays, and Saturdays.

Practice of Medicine—Three o'clock, Mondays, Wednesdays, and Fridays.

Midwifery—Four o'clock, Tuesdays, Thursdays, and Saturdays.

Dissections from sunrise to sunset; one or more of the Demonstrators being always present to give instruction.

The Professor of Botany will commence a course of lectures on Structural and Physiological Botany in February. This course, taken in conjunction with that on Comparative Anatomy and Zoology, by the Professor of Anatomy and Physiology, constitutes the course of Natural History required by the Army Medical Board.

Pupils attending the Lectures on Midwifery and Diseases of Women and Children are admitted to the practice of a recognized midwifery hospital on payment of a fee of £4 4s.

The Professor of Medical Jurisprudence gives practical instruction in Toxicology in his Laboratory.

## DISEASES OF THE EYE.

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

## CITY OF DUBLIN HOSPITAL,

Upper Baggot-street.

The Winter Session commenced on Monday, October 25.

The arrangements of this hospital are such as to afford the student an opportunity of studying disease in all its forms—Medical and Surgical. The morning visit commences daily at half-past eight o'clock, when the nature, treatment, and progress of each case are explained at the bedside of the patient, and ample opportunity afforded to every pupil of becoming practically acquainted with the uses of the Stethoscope. Clinical Lectures are delivered after the hospital visit.

Connected with the hospital is an extensive Dispensary, at which the pupils are allowed to perform the minor operations, under the guidance of the surgeons, and are rendered familiar with the details of dispensary management.

Every facility is given to students desirous of acting as Dressers and Clinical Assistants, subsequent to which all pupils of the hospital are eligible to the situation of House-Surgeon, according to merit.

A distinct course of Lectures upon Diseases of the Eye is delivered by Dr. Jacob, which the pupils are privileged to attend without additional fee, and special wards are appropriated for the reception of Eye Cases. Extended opportunities are thus afforded for acquiring a thoroughly practical knowledge of this important subject.

A ward is appropriated to the Diseases of Females, and clinical instruction is given upon all forms of Uterine Affection by Dr. Beatty.

Mr. Tufnell's course of Lectures upon Military Surgery is also open to the pupils of the hospital. This course is recognized as equivalent to six months' surgery in the professional qualification of candidates for admission into the Army, Navy, and Ordnance Medical Departments, and is required to be attended by all gentlemen entering the Hon. East India Company's Service.

A Lending Library of well-chosen books has been provided for the use of the pupils; and a correct Registry of the cases in hospital is kept by the House-Surgeon, to which they have free access.

Certificates of attendance on this hospital are recognized by all the Colleges, Universities, and Halls, and by the Army and Navy Medical Boards.

Fee for Winter six months	...	...	Six guineas.
" Summer six months	...	...	Four guineas.
" Nine months	...	...	Eight guineas.

## Medical Attendants.

- A. Jacob, M.D., Fellow and Professor of Anatomy and Physiology, Royal College of Surgeons, 23, Ely-place.  
 T. E. Beatty, M.D., Fellow and Professor of Midwifery, Royal College of Surgeons, 18, Merriion-square, North.  
 C. Benson, M.D., Fellow and Professor of the Practice of Medicine, Royal College of Surgeons, 34, York-street.  
 W. Hargrave, M.D., Fellow and Professor of Surgery, Royal College of Surgeons, 37, York-street.  
 R. C. Williams, M.D., Fellow and Professor of Materia Medica, Royal College of Surgeons, 14, Lower Fitzwilliam-street.  
 T. G. Geoghegan, M.D., Fellow and Professor of Forensic Medicine, Royal College of Surgeons, 52, York-street.  
 J. Tufnell, Esq., Fellow of the Royal College of Surgeons, 58, Lower Mount-street.

## Consulting Physicians.

Sir Henry Marsh, Bart., and Professor Apjohn.

## Consulting Surgeons.

Sir Philip Crampton, Bart., Professor Porter, and J. W. Cusack, M.D.

For further particulars apply to Dr. Benson, York-street.

Printed by Thomas Deely, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

### MISCELLANEOUS CASES AND OBSERVATIONS IN THE PRACTICE OF MEDICINE.

By J. KIRBY, LL.D.,

Ex-Professor of the Practice of Physic in the Royal College of Surgeons, &c. &c.

#### CASE OF FETID ABSCESS OF THE LUNG—TREATMENT— PERFECT RECOVERY.

Mr. K., who was under my care for secondary syphilis about four years ago, for which he underwent a mercurial course with strict confinement, and a prolonged salivation, was afterwards affected by lepra, of which he was cured by continued use of the pilulæ picis liquidæ, was attacked about the 10th of September with a violent cough, accompanied by expectoration of extremely fetid matter mixed with blood, which might have taken place in consequence of an emetic taken in bed the day before.

Dr. Neilson, to whom I am indebted for the particulars of this interesting case, observes, that the mucus was very similar to that discharged in bronchitis, and that it came evidently from the base of the right lung. For some days previously, he complained of pain in the region of the pit of the stomach, and he seemed to suffer from much hepatic derangement, for which blue pill and rhubarb pill were administered.

Some time before this he felt considerable difficulty in swallowing; and the obstruction, according to his description, seemed to be close to the cardiac orifice of the stomach. Being in Dublin some weeks before the present attack, he intended to consult me about this difficulty of deglutition; but as the inconvenience disappeared, he considered it to be unnecessary to do so.

After his late attack, he had a very severe cough, occurring in paroxysms, which caused him to gasp for breath. This he remarked to be most distressing whenever any fetid matter was about to be discharged. This has latterly diminished in quantity and foul odour, and the expectoration now consists generally of a thick, yellowish mucus, which is occasionally mixed with some purulent matter.

He never has had a rigor, but he says he has a slight perspiration. The pulse ranges between 68 and 84, and never has been higher; it is generally soft, though sometimes it is a little sharp, yet not in that degree that it would require any sanguineous depletion. The appetite is rather poor. He has suffered much sickness of stomach, especially on leaving his bed. He has occasional thirst. He feels weak, and sometimes complains of a sense of internal heat. He can lie on either side, and drawing a full inspiration does not excite coughing at first. His urine was high coloured, but it has now a natural appearance. In consequence of great sickness of stomach, he took an emetic of ipecacuanha the day before by advice of Dr. Fawcett.

At the commencement he was treated chiefly by expectorants, as mixture of myrrh, decoction of hyosciamus, with aromatic sulphuric acid. Two drops of prussic acid were also ordered, three times daily, in almond emulsion. Small doses of hippo seemed to be indicated, but they were given up in consequence of inducing sickness of the stomach. Cod-liver oil appeared to agree very well with him at first, but he loathed it after a time, and could not be prevailed on to return to its use. The diet consisted principally of jelly, revalenta arabica, barley, and other farinaceous substances, with milk.

For some days the acetic acid and turpentine liniment was applied night and morning over the whole of the chest, and afterwards a large blister, from near the spine, along the edge of the ribs, was directed, and it was subsequently continued over the pit of the stomach, care being taken to keep up a discharge for several days. This was undoubtedly of much benefit, and he seems altogether much better.

Dr. Neilson was disposed at first to think that the matter from the abscess got into the stomach by the œsophagus, but this opinion he soon ceased to entertain. The alvine discharges have been healthy throughout.

Such were the circumstances in which I was introduced to Mr. K., whom I found in bed, and tolerably cheerful.

He had a pretty good night, and ate his usual breakfast with appetite, and while we conversed, he lay on his back, with his shoulders raised on a second pillow, and his breath-

ing did not appear to be oppressed. He had a sharp guttural cough, by which he sometimes brought up mucus, brown and florid blood, and purulent matter. His voice was a little hoarse, but it was very strong, and in no other respect impaired. He sometimes coughed in his throat, as if he wanted to throw forward an elongated uvula, and this sound often preceded the bloody expectoration, which was not by any means constant in frequency, in character, or in fœtor. In his sleep he turned equally on both sides, but he thought the cough was somewhat induced when he turned to the left one. His chest, which was well developed, was perfectly free from uneasiness, except at the right hypochondrium and a corresponding part behind, for about the space of a half hand's width. This was the situation in which he first felt anything unusual, and now the sensation is rather that of uneasiness and restraint than of positive pain. He is somewhat emaciated by confinement to bed and medical discipline, and this alteration is most perceptible in his lower limbs. His pulse is as usual. He has no thirst.

The sounds of his chest are normal, except in the precise situation in which he felt any distress, and in which he believes the abscess to be placed. In these parts, and in these parts only, both before and behind, the stethoscope discovers the cavity of an abscess, with its adherent walls around it, in which there is no respiratory murmur clearly pervading the lung above the angle of the scapula, and above the sixth rib over the front part.

From the nature of the disease, its increase in spite of the remedies used, and his emaciation and weakness whenever he moved to an erect position, his friends were in much alarm as to the issue of such a malady. Nor was my opinion by any means calculated to appease their serious apprehensions. I told them it was an abscess in front of the right lung, leading directly backwards, and that foul fetid matter issued from its cavity; that the danger attending its first opening was now over, and that the suffocation, which might have taken place at the moment of its bursting, no longer threatened, as there was no evidence of any new purulent formation. I informed them that now the danger was, that the disease might expose a large vessel, and cause a copious hæmorrhage, which might be fatal in a moment, and the more remote danger of consumption; however, that as he had youth on his side, and an apparently good constitution, we should hope for the best; that we must be satisfied to wait for his amendment, and to let it spread over a length of time; that from day to day there would be but little improvement, yet that in a fortnight I did hope that matters would wear a much more favourable aspect than they bore at present.

It appeared to both Dr. Neilson and to me, that the first indication was the abatement of the cough, and accordingly Battley's sedative opium, was persisted in such doses as might have that effect. We also had in view digitalis, hyoscinus, bleeding, if required, but sparingly. The second indication was to restrain the hæmorrhage, and this we aimed at by prescribing cerussa acetata in two-grain doses every second or third hour, as also gallic acid in doses of ten drops thrice a day. The third indication was to order his diet, so as to maintain his strength, without increasing any internal inflammation which might be going on, and we ordered farinaceous and leguminous articles of nourishment. The fourth indication was to pay a gentle attention to his bowels, which we did by administering pil. hyd. and rhei at night occasionally, and aiding them by a morning injection, if necessary.

As I remained in the house two days, I saw my patient very often, but nothing occurred worthy of being remarked. However, the day after, a serious change occurred, which induced Dr. Neilson to despatch a messenger after me to Boyle, in the hope of overtaking me, but I had left an hour.

On the next day I received the following letter from Dr. Neilson:—"On Sunday morning, Mr. K. was attacked with hæmoptoe to the extent of about six ounces of blood, which was at first florid and fluid, but afterwards it was coagulated. It appeared as if lodged in the bronchial ves-

sel, or in the cavity of the abscess. I instantly gave him a gallic acid draught, and twenty drops of turpentine. I dry cupped him, and moved his bowels with an enema. He could scarcely breathe from an acute pain in his right breast, and his pulse was sharp and above 100 in a minute. He was cupped at first to six ounces, and in two hours three ounces more were taken. He was relieved. Astringents were continued during the day. No blood appears now in the sputa. He breathes easily. Expectoration is free. The only medicine taken to-day is three grains of ext. hyoscinami. It will not be prudent to give any stimulant for a few days. I gave him twenty drops of tincture of digitalis last evening, his pulse having increased in fullness and frequency. The opiate was withheld, as it seemed to tighten the chest. C. NEILSON."

On the 20th of October, Dr. Neilson informs me "that Mr. K. is considerably improved, and that as there is some excitement remaining, he will still persevere in farinaceous diet. He administered eight drops of liquor. opii sedativus at night, and an enema which, with blue pill and rhubarb, brought away solid feculent matter. He sat up for two hours the last two days, but he was very weak. He takes daily a pint of milk and flummery, revalenta, bread and tea, and ass's milk. We confine him to the plain gallic acid, his opiate, and aperient pills, &c."

On the 23rd, the Doctor informs me "that he allowed Mr. K. an egg for breakfast for two days, finding that there was an improvement, the expectoration being free, having less purulent appearance and no fœtor. He took the gallic acid mixture with quinine, which made him sick, with a tightness across the chest. It was accordingly laid aside, and the lead mixture was substituted. There was slight hæmoptysis, which made me repeat the gallic acid and lead very often, and with good effect. He feels faintish when he sits up or has an enema administered to him. He has taken ten drops of Battley's sedative for the last two nights, and I purpose increasing the dose this evening. He thinks it answers well. He feels to-day better than he has felt since the commencement of the attack."

On the 25th, "the bloody sputa continued, though he persevered in the use of the acetate of lead to twenty grains, and at length he lost about ten ounces of blood, when he got a gallic acid draught, twenty drops of turpentine, and an ounce of infusion of digitalis soon after. His pulse was 100. It was agreed by Drs. Fawcett and Neilson to give the gallic acid draught every third hour, and to attend to the bowels, which, continuing the usual pills, required the assistance of pil. colocynth comp. and ext. hyoscinami, which produced dark motions, resembling swallowed blood. He expresses himself as much easier. I have been just requested to place these matters before Sir Henry Marsh and Dr. Stokes if agreeable to you."

Now, I am one of those persons who adopt a line of conduct from mature deliberation, and thus nothing can change my mind. Here I saw there was nothing which would prevent the hæmorrhage occurring, and therefore I was content to await the effect of the remedies now in use before we had recourse to any other, and I therefore readily availed myself of the advice I was directed to procure, and I accordingly submitted Dr. Neilson's statement to both these gentlemen.

Sir Henry Marsh advised salicine and ext. anthemidis in pills of one grain three times a day; and Dr. Stokes recommended a perseverance in the remedies which were being employed.

On the 28th of October, the hæmorrhage slightly returned, and there was retention of urine, which required the catheter. There was great weakness on moving to the erect position.

The 30th of October there was some return of the hæmorrhage, but otherwise the expectoration has been clearer for some days, and this morning it is nearly white. His strength improves. His pulse is from 84 to 90, so he has lost no ground for some days, and his cough is less troublesome, being controlled by Battley's sedative every night. He rejoices he has your permission to have an egg, and he

will try the beef-tea as you recommend. There are in the day about seven ounces of expectorated matter, which had a bronchitic character.

Dr. N. informs me that there was no appearance of blood for the last three days; that the expectoration was free; and that there was but little fœtor. His strength is decidedly increased. His bowels are opened by enema every second day. He perseveres in his farinaceous diet, with the addition of an egg. His medicines are taken pretty regularly. To the Doctor's wish respecting the increase of the salicine, I do not accede, as it may be too stimulant, and it is better to make no change at present. I am satisfied that matters are going on reasonably well.

November 12th: Mr. K. has been going on favourable. The expectoration is free, and much lighter in colour. His strength is much improved, though he has not been out of bed. His cheeks and temples begin to fill. He feels the air to pass more freely through the right lung, and his cough is less troublesome; tongue soft and clean; pulse as usual; urine natural; he sleeps well, and generally on the left side, and breathes most easily; his appetite is better; he lives on his egg, three pints ass's milk, revalenta, and stirabout; he takes his blue pill and rhubarb; he now takes an increased quantity of salicine and Battley's sedative at night, with twenty drops of nitro-muriatic acid in the day. No fœtor since I last wrote.

23rd: Mr. K. improves, but still does not leave his bed. A day or two since he had a pain in the old situation on coughing on making a full inspiration; but it does not appear to be of much moment. He withdrew the salicine for two days at the suggestion of Dr. Fawcett, although he believed it to have been of use, and I strongly advised a return to it.

It appears from his letter of the 23rd, that "there is a great improvement in every way; but that in consequence of the severity of the weather, he has not as yet left his bed. He has returned to the salicine, and his treatment in point of medicine is as before." He adds, "I have examined the chest, and I think the right lung is now permeable to air, although pectoriloquism is still present."

December 7th: Mr. K. had a slight return of hæmorrhage to day, and a fetid discharge from the abscess; he takes Battley's sedative at night and the salicine and gallic acid, which he reports has done good.

14th: Mr. K. goes on well; he walks about the room, and goes from one room to another; no change whatever has been made in treatment. Dr. Fawcett is anxious to give up the salicine and Battley's sedative, the latter for some other anodyne, but I cannot see the propriety of throwing aside remedies which are beneficial, on the chance of others doing as well. Again, he says, the salicine has been of use.

On the 2nd of January, Mr. K. is reported to be significantly improved, and to have been about for several days; the cough and expectoration are much diminished; bowels regular, and the pulse 70.

15th: Mr. K. is getting quite fat; he coughs very little in the day time, but he feels some uneasiness in the side occasionally.

I now heard nothing more of Mr. K. In about six weeks he came to Dublin with his physician, and Sir Henry Marsh and Dr. Stokes met in consultation. He had wholly recovered his flesh and good looks, though on a very abstemious diet and the avoidance of wine and every stimulant. All his functions are regularly performed, so that a very little medicine was necessary. He had still severe cough, and periodically a little appearance of blood in the expectorated sputa, which he thought to come from beneath the third or fourth rib. He still referred to the original seat of the attack, and said there was a sense of restraint in that part; however, the stethoscope did not indicate anything there beyond a slight dulness and a little resonance of the impermeable state of that part of the lung. We did not advise any new medicine. We desired him to observe his usual manner of living; and above all things, his abstinence from wine and stimulants, except a pint of beer, for which he begged most earnestly, to clothe himself care-

fully, to avoid night air, and as yet not to take exercise on horseback.

Since then Mr. K. has often been in town, and always called to see me, or "rather to show himself to me." He still has a mere slight periodic return of the sanguineous discharge, and on one occasion he was so alarmed as to send for me at night; but before I arrived, it had nearly ceased. However, he took his lead draught and gallic acid, and remained quiet for two days, when it wholly disappeared. I examined the internal fauces, and I am quite persuaded that the hæmorrhage came from an elongated uvula, which I recommended him to have removed; but this he declined to do.

This is the history of an important case, and it therefore deserves a few observations, which I am the more disposed to give, in consequence of the infrequency of the disease, which is here called a Fœtid Abscess of the Lung, not a sloughing abscess, as from such fœtor is never absent. How far his new disease is to be attributed to his old syphilitic affection, it is not easy to decide, but it is evident it was got rid of without recourse being had to any mercurial remedy. Indeed the question was once entertained by the medical persons who attended him, but both very properly yielded their judgment to Sir B. Brodie and to me who treated Mr. K.

It is to be remarked, that some time before this severe attack, he had a difficulty of swallowing, and the obstruction seemed to be near the cardiac orifice of the stomach, but this disappeared, and is not to be explained on any pathological principles, although it might be on those which are functional.

He is now (September 20th) attacked with the symptoms detailed in the history of the case, and he was managed as is there laid down.

At my first interview a plan of treatment was laid down in accordance with the indications which then suggested themselves to me, and which, by Dr. Neilson's good sense and perseverance, were steadily, and as far as possible, carried through. With the exception of Sir H. Marsh's prescription of salicine and ext. anthemidis, there was no material interruption to opiates, laurel water, digitalis, tincture of hyosciamus, to allay the cough and diminish the irritability of the pulmonary system. Acetate of lead, so justly, I say (from the fullest experience of now half a century) extolled by Sir G. Blane, Heberden, and Chapman in his "Therapeutics," was foremost in my commendation. It was given in pill, in draught with vinegar, and in combination with sulphate of quinine, to allay the hæmorrhage from the lungs. Gallic acid was a second most powerful agent, and was confidently employed with the same view.

By the use of these three medicines, Mr. K.'s case ran to a favourable issue, not meaning by any means to detract from the first treatment to which he was submitted.

This case exhibits with clearness the dangerous mischief of heaping a variety of remedies on any patient at short intervals, and well declares the advantage of reliance on a few which are first well chosen.

It is now two years from the period of attack, and Mr. K. continues to enjoy excellent health. He is still very apprehensive of a return of his disease.

(To be continued.)

**SYPHILIZATION IN FRANCE.**—A very animated discussion has lately taken place before the Academy of Medicine of Paris, touching a method of a M. Auzias Turenne, who proposes to use the syphilitic virus like cow-pox matter, and to inoculate it until the individual becomes proof against the disease. The same author likewise advocates, and has practised, the inoculation of the pus taken from chancres for the cure of primary and syphilitic affections. The Academy has reprobated the practice almost unanimously; the two members of the learned body who gave their support to this insane proposal, are Messrs. Malgaigne and Depaul.

WESTERN MEDICAL AND SURGICAL SOCIETY  
OF LONDON.

MR. CHATTERLEY read a paper

## ON THE THERAPEUTICAL EFFECTS OF GOLD.

The author commenced by saying his attention had been drawn to this subject during the treatment of a very obstinate case of scrofula, in which large, indolent, and spreading ulcers existed over the joints of the big toe of the right foot. From this patient he had previously removed the little finger of the left hand on account of ulceration of the cartilages of one of the joints. Previous to the operation, and during the healing of the wound, the iodide of iron had been given almost continuously; and in spite of this, combined with other treatment, the ulcers on the toe continued to increase. By the advice of a medical friend, Mr. Chatterley was induced to try the effects of gold, from which his patient derived such marked benefit, that he was led to investigate the subject further. Gold appears to have been in use among many practitioners in France, Italy, Germany, and Poland, for the last fifty years, and has been reported upon most favourably by them, and amongst others, by Magendie, Dumeril, and Roux, to the Academy of Sciences of Paris. Four preparations appear to be in ordinary use—1st, the perchloride of gold and sodium; 2nd, the oxide of gold (precipitated by potass or magnesia); 3rd, the stanate of gold; 4th, the metal in a state of fine powder. The first is the most powerful, and is used in doses of one-thirtieth to one-third of a grain, mixed with some inert powder, in the proportion of three parts to nine. It is directed to be rubbed on the tongue for a period of from one to five minutes. An increased flow of saliva is the consequence of this friction. It may be given internally, but in very minute doses, as it is apt to excite inflammation of the stomach, and is also very liable to decomposition. The powder has been administered by cutaneous absorption, when the state of the tongue and mouth has prevented the use of the ordinary frictions. The author then proceeded to describe its action upon the system, stating it to be principally stimulant, affecting the stomach primarily, the kidneys, and the bowels. The flow of urine is usually most abundant. The cases which appear most suited for its use are scrofula, syphilis, and syphilitic eruptions, and perhaps cancer.

Dr. ALDIS presented a specimen of perforating ulcer of the stomach, removed from a female of forty years. The characteristics of the ulcer were well marked. Death occurred within thirty-six hours of the attack.—*Lancet*.

CASE OF HERMAPHRODISM—CASTRATION—A  
NEW PRINCIPLE IN JURIDICAL MEDICINE.

By S. D. GROSS, M.D.,

Professor of Surgery in the Medical Department of the  
University of Louisville.

THE following case, which came under my observation in 1849, will, if I mistake not, prove both novel and interesting to my professional brethren. So far as my information extends, there is no account of any operation for a similar object upon record.

The subject of the case, at the time I first saw her, was three years of age, having been born on the 10th of July, 1846. She had always, up to this period, been regarded as a girl, and had been so pronounced at her birth by the accoucheur. At the age of two, however, she began to evince the tastes, disposition, and feelings of the other sex; she rejected dolls and similar articles of amusement, and became fond of boyish sports. She was well-grown, perfectly healthy, and quite fleshy. Her hair was dark and long, the eyes black, and the whole expression most agreeable. A careful examination of the external genitals disclosed the following circumstances:—There was neither a penis nor a vagina; but, instead of the former, there was a small clitoris, and, instead of the latter, a superficial depression, or *cul-de-sac*, covered with mucous membrane,

and devoid of everything like an aperture or inlet. The urethra occupied the usual situation, and appeared to be entirely natural; the nymphæ were remarkably diminutive; but the labia were well developed, and contained each a well-formed testis, quite as large and consistent as this organ generally is at the same age in boys. Her hips and chest, thighs and superior extremities, were perfect.

It being apparent, from the facts of the case, that it was one of malformation of the genital organs usually denominated hermaphroditism, the question occurred whether anything could or ought to be done to deprive the poor child of that portion of the genital apparatus which, if permitted to remain until the age of puberty, would be followed by sexual desire, and which might thus conduce to the establishment of a matrimonial connection. Such an alliance, it was evident, could eventuate only in chagrin and disappointment, if not in disgrace, ruin of character, or even loss of life. Certainly, impregnation could never occur, and even copulation could not be performed, except in the most imperfect manner.

I need not say that I gave the subject all the consideration and reflection that I was capable of bestowing upon it. I was deeply sensible of the responsibility of my position. A new question, involving the rights and happiness of my little patient, and the dearest interests of her parents, was presented to me. I examined the case in all its bearings and relations—moral, physiological, and juridical; I appealed to the records of my profession for precedent, and I sought the counsel of medical friends. The parents were anxious for an operation; they were intelligent, kind, and tender-hearted, and were willing to sacrifice everything for the welfare of their child. Their only object was to save it from future suffering and misfortune. My own mind was made up; but, before I proceeded to take any further steps, I determined to consult my excellent friend and colleague, Professor Miller, in whose judgment and integrity every one who knows him has the utmost confidence. He saw the child and examined her. He viewed the case, as I had previously, in every possible aspect, and his conclusion was, that excision of the testes was not only justifiable, but eminently proper under the circumstances; that it would be an act of kindness and humanity to the poor child, standing as she did towards society in the relation, not of a boy or a girl, but of a neuter, to deprive her of an appendage of so useless a nature; one which might, if allowed to proceed in its development, ultimately lead to the ruin of her character and peace of mind.

Backed by such authority, I no longer hesitated what course to pursue. I performed the operation of castration on the 20th of July, 1849, aided by my pupils, Dr. D. D. Thomson, of this city; Dr. Greenburg R. Henry, of Burlington, Iowa, and Dr. William H. Cobb, formerly of Louisville, now of Cincinnati. The little patient being under the influence of chloroform, I made a perpendicular incision, about two inches in length, into each labium down to the testis, which was then carefully separated from the surrounding structures, and detached by dividing the lower part of the spermatic cord. The arteries of the cord being secured with ligatures, the edges of the wound were brought together with twisted sutures, and the child put to bed. Hardly any blood was lost during the operation. About two hours after, the left labium became greatly distended and discoloured; and, upon removing the sutures, the source of the mischief was found to be a small artery, which was immediately drawn out and tied. No unpleasant symptom of any kind ensued after this, and in a week the little patient was able to be up, being quite well and happy.

The testes were carefully examined after removal, and were found to be perfectly formed in every respect. The spermatic cords were natural.

I have seen this child repeatedly since the operation, as her parents live only a few squares from my office, and have carefully watched her mental and physical development. Her disposition and habits have materially changed, and are now those of a girl; she takes great delight in

sewing and house-work, and she no longer indulges in riding sticks and other boyish exercises. Her person is well developed, and her mind uncommonly active for a child of her years.

I would fain present this example as a precedent in similar cases. The reasons which induced me to recommend and perform this operation in the instance before me have been already mentioned, and now, after a lapse of three years, I have no cause to regret undertaking, or to think that I acted harshly and inconsiderately. If the records of surgery and medical jurisprudence are silent upon the subject; if the learned doctors of the Sorbonne, the fathers of the Royal Academy of Paris, and the Fellows of the Royal College of London have left us no precepts; and if the experience of the present day furnishes no examples; all this, and much more, does not prove that the practice here recommended is not perfectly just and proper, and vindicated upon every principle of science and humanity.

A defective organization of the external genitals is one of the most dreadful misfortunes that can possibly befall any human being. There is nothing that exerts so baneful an influence over his moral and social feelings, which carries with it such a sense of self-abasement and mental degradation, or which so thoroughly "maketh the heart sick," as the conviction of such an individual that he is for ever debarred from the joys and pleasures of married life, an outcast from society, hated and despised, and reviled and persecuted by the world. Nothing but the most perfect resignation, and a well-founded confidence in the mercy and justice of the Creator, can render the lot of such a being at all supportable.

The subject of doubtful sex is one which has always, in all ages, and in all civilized countries, excited the warmest attention of the physiologist, the philosopher, and the medical jurist. Under the vague and ill-chosen name of hermaphroditism, invented at an early period of the world, was described every imaginable form of malformation of the genital and urinary organs, most dissimilar in character; and, consequently, were calculated to mystify and mislead the public mind. A class of beings was imagined, combining, it was said, the qualities of the male and female in the same individual, and capable of performing, within itself, the generative functions. The idea that such a union might exist, had its origin, no doubt, in fable. The reader of mythology need not be reminded here of the story of Hermaphroditus and the nymph Salmacis; how the former so ungallantly resisted the charms and entreaties of the latter, and how, finally, through the interposition of the gods, their bodies were united into one. The ignorance of medical men, the conceit and folly of legislators, and the mercenary conduct of many of the subjects of this variety of congenital malformation, served, afterwards, in no small degree, to perpetuate the error thus engendered, and to transmit it, in nearly all its ancient form, down to a comparatively recent period. Modern researches had done much to dissipate these absurdities, when the publication, in 1836, of the great work of Mons. Isidore St. Hilaire, entitled "*Histoire des Anomalies de l'Organization*," set the long agitated question for ever at rest, by demonstrating, in the most undeniable and conclusive manner, that there is no such thing as hermaphroditism, in the vulgar acceptance of the term; or, in other and more philosophical language, that the union of perfect male and female organs in one and the same individual, is an anatomical and physiological impossibility.

Much prejudice, leading often to the most cruel persecution, existed against this class of individuals among some of the nations of antiquity. The Athenians had a law, providing that all hermaphroditic children should be consigned to the flame; while the Romans ordained that they should be boxed up, and thrown into the sea. In more recent times, all individuals of this description were excluded from holy orders, and from the office of judges; "because they were ranked with infamous persons, to whom the gates of dignity should not be opened."—(Beck's Medical Jurisprudence.) Much of this prejudice

has, fortunately, disappeared, under the benign influences of Christianity and civilization; but much still remains, and must continue in operation, as long as the human mind retains its present organization. If hermaphrodites are no longer burnt and drowned, stoned and persecuted, and mocked and reviled, they are universally regarded with a degree of prejudice, amounting generally to positive aversion; and as unfit for any offices of dignity, divine, legal, or political. If such be the fact, and no one can doubt it, every suggestion, calculated to ameliorate the condition of this unfortunate class of beings, by depriving them of their only incentives to matrimony, and thereby dooming them to everlasting celibacy, should be hailed as a valuable contribution to the science and humanity of the present age.

On this, the Editor of the *American Journal* remarks:

"We have willingly given place to the above communication, not only because it is a very interesting and curious one, but also from the respect we entertain for the opinions of its distinguished author; but in doing so, we may be allowed to say that we cannot feel satisfied with the soundness of his argument in the present instance, and that while we will leave the discussion of the subject to those more competent to the task, we may add, that it appears to us the administration of prussic acid to terminate the sufferings of those afflicted with malignant disease, or who have received severe and irremediable injuries, might be justified by the same train of reasoning."

And so say we also. If we had to legislate for an Utopia, we might provide for similar difficulties, and suggest clauses in acts defining the lengths to be gone in the paring down of superfluities, especially sexual ones. But as it is, we seriously advise our brethren on this side of the Atlantic to refrain from castrating children, be the impulse to do so ever so powerful, or the consequences to be apprehended from their genital developments ever so alarming. We do not deny that great results might flow from a judicious adaptation of this means towards civilization, but then the law at present does not sanction the practice.

#### CASE OF FOREIGN BODY LODGED IN THE AIR-PASSAGES FOR FOUR YEARS AND A HALF; TERMINATING FATALLY BY GANGRENOUS ABSCESS OF THE RIGHT LUNG.

By JAMES STRUTHERS, M.D., Leith.

In October, 1844, Thomas Neal, a footman, æt. 22, while eating part of a fowl, and laughing at the same time, was suddenly seized with a violent fit of coughing, and a feeling of suffocation; he became blue in the face, felt a sharp pain in the chest, and was sensible of part of his food having entered the windpipe. These symptoms subsided in about half an hour, and never returned. An emetic was administered, and acted freely; and both fluids and solids were swallowed without difficulty. From about an hour after the accident a tickling cough, with a wheeze in the throat, continued to trouble him occasionally, but gave little inconvenience; and he went about his work as usual, as if nothing had happened. He still, however, was impressed with the conviction that there was something in his windpipe, and pointed to a spot a little to the right of the upper part of the sternum, saying that he felt it there.

About three months after the accident, the cough began to be accompanied by the expectoration of white frothy sputa, which, without any other change in the symptoms, gradually increased in quantity during the ensuing twelve months. At the end of that time he was seen on several occasions by Sir Benjamin Brodie, and entered St. George's Hospital, London, where he remained for a fortnight, and was then advised to go to the country. About a month afterwards he, for the first time, observed the sputa to be tinged with blood, and to have a fetid odour. During the two following years the cough was more frequent, the ex-

pectoration very profuse, and the quantity of blood in the sputa gradually increased, as did also the fœtor of the breath. This last symptom became so marked in 1848 as to oblige him to leave his situation, for which he was in every other respect fit. During the greater part of 1848, he had exacerbations of the cough every two or three weeks; at these periods there was increased fœtor of the breath, the sputa contained a considerable quantity of florid blood, and he occasionally brought up as much as half a pint of pure blood at a time. In the beginning of November, 1848, he had a rigor, followed by pain in lower right side, increase of cough, and shortness of breath, and the sputa became of a brown colour (pneumonia?); for this he was treated by a physician in Musselburgh. In the beginning of the following month, he entered the Royal Infirmary of Edinburgh, under the care of Dr. Bennet. He was then pale, but by no means emaciated; he complained a good deal of cough, which occurred at frequent intervals, and was accompanied by profuse expectoration of viscid sputa, very fœtid and stained with blood. On examining the chest, there was dulness on percussion over the inferior three-fourths of the right side, both in front and behind, but most decided a little below the nipple. The left side was resonant throughout.

On auscultation, the vocal resonance was found increased over the whole of the right side, particularly at a spot a little below the nipple. At the middle of the same side, posteriorly, a gurgling râle was heard over a space two inches square; in the other parts of this side, the respiratory murmur was very harsh, and much obscured by mucous and sibilant râles; it was least affected at the apex. On the left side, the respiratory murmur was puerile throughout, and unaccompanied by any râle. The appetite was good; bowels regular; urine healthy; he slept well; was free from pain; and the voice was unaffected. During the next three months, there was but little change in his condition. For weeks at a time the sputa were free from blood; but every two or three weeks they became bloody for several days at a time, and then also the cough was more frequent, the expectoration more profuse, and the fœtor of the breath and sputa greatly increased; while the urine deposited large quantities of pink urate of ammonia, and contained numerous crystals of the oxalate of lime. After a residence of three months, he left the infirmary in the beginning of February, 1848. For the next six weeks he enjoyed tolerable health, being able to walk a considerable distance without inconvenience, experiencing shortness of breath only on walking fast; the cough continued pretty constant, with copious expectoration of whitish sputa, generally fœtid, and only occasionally tinged with blood. Once or twice he expectorated several small masses of a brown colour and of some consistence; these he imagined to be portions of the foreign body.

Towards the middle of March his appetite and strength began to fail; he lost flesh and became feverish, thirsty, and restless; was obliged to confine himself to the house; and suffered from shortness of breath, even when at rest; the cough and expectoration continued much the same; he had no rigors, and was free from pain. On the morning of the 24th, he awoke suffering from great increase of cough and shortness of breath, and continued during the day to expectorate, at intervals of a few minutes, large quantities of frothy sputa, deeply tinged with blood, and much more fœtid than usual. I was asked to visit him at his own house on the 25th, and found him much weaker than when I had last seen him, some weeks previously. The cough was constant, the expectoration profuse, the sputa frothy and mixed with florid blood; the breath and sputa had a gangrenous odour, which was very perceptible on approaching the bed. He had no pain, his chief complaint being of great weakness, dyspnoea, and occasional feeling of suffocation. The respirations were 45; the pulse 130, weak and wiry. On examining the chest, the right side was found scarcely to move on inspiration, and was universally dull on percussion; all natural respiratory sound was absent; gurgling was audible over the

greater part, both in front and behind, with coarse mucous and subcrepitant râle, towards the upper and lower parts. Although the voice was weak, the vocal resonance was much increased, and there was very distinct bronchophony over the inferior two-thirds. There was no friction sound audible. The left side was very resonant, and, with the exception of puerile respiration, and some subcrepitous râle, inferiorly, presented nothing unusual. During the next three days, he became rapidly weaker; the cough and dyspnoea increased; he could speak only in monosyllables; the respirations rose to 68, and the pulse to 140; and he expectorated daily about two pints of thin bloody sputa, which had a strong gangrenous odour, and latterly flowed in an almost continuous stream from the mouth. On the 29th, he became typhoid; had hiccup and slight delirium, and died in the evening.

*Sectio Cadaveris.*—Along with Dr. Alison, who had seen the case with me during the last two days, I made a post-mortem examination of the body twenty-two hours after death. The features were much collapsed; there was some yellowness of the skin; and a copious discharge of thin brown fluid from the mouth and nostrils. Percussion of the chest elicited the same sounds as during the last days of life.

On opening the *thorax*, the right lung, with the exception of the lower part of the anterior border, was found firmly adherent to the walls. The adhesions were short, dense, and of a white colour. The lung was removed without laceration; it was somewhat diminished in bulk, of a dark red colour, and had a pulpy feel. The apex was occupied by a closed cavity, the size of a small orange, which was distended with a brown dirty-looking fluid of the consistence of cream, and having a most intense gangrenous odour. The wall of this cavity approached the pleura superiorly; its inner surface was very irregular, presenting numerous shreds of disorganized pulmonary tissue. At the middle of the lung posteriorly, and about half an inch from the surface, there was another cavity, the size of a walnut, lined with a dense gray-coloured membrane, one line in thickness, and broken up in several places; it was partially filled with a dirty-coloured fluid, and opened directly into a bronchial tube, the size of a crow quill, at the other extremity of which the foreign body was found at a future stage of the dissection. In the neighbourhood of this cavity, and throughout the whole of the inferior and posterior parts, the lung was riddled with numerous small cavities, varying in size from that of a hazel nut to that of a pea. Some of these were closed and filled with a fluid similar to that found in the one at the apex; others were nearly empty, more or less anfractuous, and communicated freely with the bronchial tubes; the walls of some were formed of a thick dense membrane, those of others were soft and ragged. The middle part of the anterior, and a small portion of the inferior, border were in a state of gray hepatisation, and were the only parts free from cavities. On laying open the *right* bronchus, a small piece of bone was found at the bifurcation of the middle primary division; it was lying almost loose, and came away without any force being used; it was quite clean, and bore a strong resemblance to part of a vertebra of a small animal, being of an irregular elongated form, and presenting several sharp spicula. The mucous membrane at the part was thickened, but quite free from ulceration, and not more vascular than that of the other bronchi. The *trachea* and the *bronchi* of both lungs were stained of a dark gray colour, but otherwise presented nothing abnormal. In the left *pleura* there were three or four ounces of clear serum. The lung was healthy, except a small portion at the inferior border which was hepatised, and studded with small, gray, indurated nodules, the size of corn-pickles. These consisted, as ascertained by the microscope, of accumulations of altered epithelium, with much granular fatty matter. The apex of the lung was free of deposit, and there was no tubercle in any part. The *bronchial glands*, especially those on the right side, were greatly hypertrophied, several of them being as large

as pigeons' eggs; they contained no foreign matter. The heart was of the normal size; its muscular and valvular structures were healthy; and all the cavities contained both firm decolorized and dark loose clots. The blood, examined under the microscope, presented the red and white corpuscles in the usual proportions. The abdominal viscera were in all respects normal.

The fluid from the abscess at the apex of the right lung, on being examined under the microscope, was found to contain small shreds of fibrous tissue, broken down pus globules, and a large number of crystals of the triple phosphate and of the urate of ammonia.

*Remarks.*—This case presents a very good illustration of the length of time during which a foreign body may remain in the air-passages without giving rise to any urgent symptoms. There can be no doubt that the freedom from distress was due to the bone having, almost from the first, become fixed in the bronchus, and having remained in the same position till death. Had it either been fixed in the larynx or trachea, or remained loose in the passages, it must have given rise to a train of symptoms quite different from that manifested throughout the case. For three months, the only symptom of there being anything amiss in the chest, was the occasional occurrence of slight cough and wheezing, resulting, most probably, simply from irritation, and not from the body becoming loose in the passages. At the distance even of fifteen months, so slight was the disturbance of the respiration, and so doubtful the evidence of the existence of a foreign body, that Sir B. Brodie (the patient informed me) expressed his opinion that there was nothing in the air-passages, and considered the case one of chronic cough, from which recovery might soon take place. A similar opinion seems to have been entertained of the case when under treatment in St. George's Hospital, as no proposal was ever made to the patient to have an operation performed; nor, indeed, would such have been justifiable unless, on physical examination, undoubted evidence of obstruction in the chest had been discovered. It was not till a month after he had left London, and sixteen months after the accident, that the sputa became bloody and fetid; and this seems to have been the period at which the disorganizing process first commenced in the lung. The importance, in such cases, of having recourse to the stethoscope, and of not trusting to the disappearance even of every symptom of the presence of a foreign body soon after its supposed entrance into the air-passages, is still better illustrated by a case mentioned by M. Louis, in which, after the first few minutes, the patient for a whole twelvemonth had not a single bad symptom; at the end of that time the foreign body (a cherrystone) was expectorated; a copious purulent expectoration followed, and the patient died exhausted in three days. The first opportunity I had of examining Neal was in the latter end of 1848, four years after the accident. The history of the case then was such as to excite a suspicion that a foreign body had entered the air-passages at the time supposed by the patient, and had remained there ever since; while the physical examination of the chest established the existence of an open cavity of some extent near the middle of the lung. Such being the state of matters, all operative interference seemed to be contra-indicated; as, even had all doubts of the presence of a foreign body been removed, the probability was that it would be lying in the cavity, and therefore beyond the reach of instruments. I am not aware of any case of recovery, whether spontaneous or by operation, being on record in which more than two years had elapsed from the date of the accident. In those which have lasted longer, death took place sooner or later from disorganization of one or both lungs, either from tuberculosis or gangrene; and the fatal issue would seem to have been equally certain, whether the foreign body remained in the lung or was expelled by the efforts of Nature. When the latter event has taken place, as it has done ten or even seventeen years after the accident, the case has either terminated suddenly, or the morbid process has gone on unchecked by the removal of its original cause, the disorganization which had taken

place before the expulsion having been so great as to prevent recovery. Had the bone been removed in this case, even four years after the accident, there is good reason to believe that recovery would have taken place, as only a small portion of the lung was seriously implicated, the general symptoms mild, and the constitution of the patient but little affected. A point of considerable pathological interest in the case, is the absence of all ulceration at the part where the foreign body was impacted; the only change discovered, after careful examination, being thickening of the mucous membrane. That the bone must have remained all along in the place where it was found, is almost certain; otherwise, from its comparatively small size and spongy texture, it would have been frequently projected up to the larynx, giving rise to paroxysms of cough, none of which ever occurred; besides, there was no thickening of the mucous membrane in any other part; and the cavity which was first formed opened directly into the tube at the mouth of which the bone lay. Another point of pathological interest, was the existence in the fluid from the gangrenous abscess at the apex of the lung of large quantities of the crystals of the triple phosphate and urate of ammonia, formed, no doubt, on the spot by the destruction and decomposition of the surrounding tissue. Their form was exactly the same as that in which they exist in the urine.—*Edin. Monthly Jour.*

#### PRECOCIOUS DEVELOPMENT OF THE MALE SEXUAL ORGANS IN A CHILD FOUR YEARS OLD.

By ROBERT KING STONE, M.D.,

Professor of Physiological Anatomy in the National Medical College, and one of the Surgeons of the Washington Infirmary.

Mr. Charles —, of this district, brought his son, Theodore, to my house on the 14th of September, 1852, his birthday, for my inspection and opinion; stating that on that day he was four years old. I at once declared my incredulity, for his height and robust development seemed those of a child at least six years older than the age he mentioned. My astonishment was greatly increased when, on stripping the boy, he offered to my view the well-developed sexual organs of a man, and the pubes covered with a luxuriant growth of hair. I was perfectly incredulous that the boy was born on the 14th of September, 1848; but his father said he could produce his certificate of nativity, and that he, with his mother, the midwife who delivered him, and fifty other responsible persons, would swear that he had stated his age correctly. The boy is remarkably handsome, and when stripped, presents a form of great beauty, which is, in fact, a miniature model of a perfectly developed athlete. The condition of his muscular and osseous system is extraordinary; the deltoids and other muscles of the arm, forearm, back, and thorax, have the same relations to his height that those of a hard-labouring man would have of the stature of six feet. The muscles of the thigh, gluteal region, and leg, are perhaps better developed than those of the upper extremity, but in nearly the same ratio to the height. If the child's face is concealed the examiner would declare his figure to be that of a miniature man, perfectly developed, and at least 21 years of age. There seems to be little adipose tissue about him, the muscular prominences being clear, and well defined, as if produced by constant exercise or hard labour. The growth of hair is distinct in the axilla, but by no means so marked as that upon the pubes. As in every robust man, the lumbar and sacral regions are covered with a thick down of dark hair. His height is now four feet one-quarter inch, and weight nearly seventy pounds; though his mother informs me he weighed seventy-five pounds in the spring, and attributes his diminution to the great number of lumbricoides which infest him. His penis is that of a well-developed man, measuring in a semi-flaccid state four and a quarter inches in length, and in the state of perfect flaccidity three and a half inches. The prepuce is short, leaving exposed a perfectly formed glans penis. I might state, also, that the papillæ of the corona

glands are in a state of hypertrophy, being distinctly salient, and exquisitely sensitive. The pubes are covered with a luxuriant growth of crisp, curling, dark-brown hair, as found in the adult state. In the scrotum, presenting the appearance of the adult, are two firm, apparently well-developed testicles, perhaps rather under the average size of those organs in the adult. Independently of the penis, the development of these alone would have been decidedly remarkable at that tender age. The spermatic cords are distinct, and under the finger give the impression of perfect organs. Carefully examined from the neck down, the appearances are those of a *perfect man*, whilst the head and face were those of a child. On examining his mouth, it was found to contain only the twenty deciduous teeth of his age, with the exception of the middle incisors of the upper jaw, which were carious to the fangs. The head was perfectly formed, and bears a proper proportion to the development of the body. The breadth between the ears across the cerebellum was great; in fact, the anterior development of the cranium was less than the posterior; yet the relation could not be called bad at his early age. The boy is lively, and seems intelligent, though his speech is imperfect, but he pronounced with facility after his father. He seemed unwilling to talk of his own accord before strangers; his father informs me, however, that he is very talkative at home and quite intelligent. His temper is good, and he is almost always in good-humour, but when excited by anger, his father alone can manage him, which he does by an old-fashioned knock-down blow. His father observed last night, when he slept with him for the first time, a constant erection of the penis, accompanied by a nicker, like an excited stallion, and for these reasons consulted me. The boy has almost always slept by himself, and on a hard pallet on the floor. His back and shoulders are covered with the *acne simplex* of puberty. He has never been known to attempt masturbation, nor is it known whether he has had sexual relations, although the organ has that appearance. The slightest touch of the penis excites it, and the organ becomes tumid and of the average adult size, during the requisite examination. The voice is that of puberty, and has been so for some time. He is the seventh child and third son of his mother; weighed eleven and a half pounds at birth, and fifty-six pounds at three years. At birth, the glans penis was perfectly uncovered, and the hair on the pubes half an inch long; at one year, things were just as they are now. Although his neck is full, there is no remarkable development of the laryngeal cartilages, *Pomum Adami*. The next question is in regard to the power of the testicles to secrete. Since I first saw this man-boy, his father has made inquiry as to this fact, and states the following to me as the result:—On the 13th of September, he slept with a near relative, a married lady, the mother of several children. In the middle of the night she was aroused by finding the boy closely clasped to her back, and her night-dress saturated. She thought he had emptied his bladder upon her, but on carrying her hand to the part, she found that it was saturated with a *very different and glutinous material* from that she expected. I regret that I could not obtain the ejected matter to submit it to a microscopical test. The boy is extremely fond of embracing the opposite sex, though nothing further has been ascertained. In no other of the seven children borne by the same mother has the same condition been observed, and in comparing an elder sister of ten years, I found she was extremely delicate, and only half an inch taller than Theodore. I have several times seen him during an attack of nicker, and am satisfied that it is produced by a tendency to epilepsy.—*Amer. Jr. of Med.*

THE SYPHON-DOUCHE IN ENGLAND AND FRANCE.—M. Maisonneuve presented a short time back, to the Academy of Medicine, an apparatus whereby the cervix uteri and vagina may be conveniently douched. The contrivance is exactly similar to that lately introduced by Dr. Jones; but the English inventor is not mentioned by his French professional brother.

## HOSPITAL REPORTS.

*Peculiar Mode of administering Copaiba.*  
(Under the care of Mr. LLOYD, Mr. POLAND, and Mr. LEGROS CLARKE.)

It has been noticed that such patients as were purged by the copaiba evacuated per anum large quantities of this drug in an unaltered state, their urine not containing any of it. These persons, though sometimes cured, generally had a relapse. Those, however, who were not purged became well more slowly, and had no recurrence of the disease; their stools contained no copaiba, and their urine a great deal. From these facts it became evident that in order to obtain regular and speedy effects, the copaiba should be made to undergo such modifications as to ensure its more complete absorption into the system. Experiments were now instituted respecting the effects of the two principal substances contained in the copaiba—viz., the oil and the resin. These were separately tried. The oil produced a decidedly purgative effect; the resin purged less; but no complete cure was obtained by either substance taken separately.

It was now pretty clear that both the resin and essential oil were indispensable for obtaining curative effects, and the question arose how these could be modified so as to allow the stomach to digest them completely. This end was attained in surcharging the copaiba with oxygen, by means of nitric acid, the latter being added in proportions which varied according to the kind of copaiba acted upon. The nitric acid yields some of its oxygen to the essential oil, and the nitrogen is given off in the form of hyponitrous acid, by combining with the oxygen of the atmosphere. The copaiba thus treated is then well washed with water, until it no longer reddens litmus paper, and to it are added one-tenth part of cubeb in fine powder, the same proportion of carbonate of soda, and one-sixteenth part of calcined magnesia. The mixture is allowed to stand until it is quite solidified, and in that state it is made into small masses. The latter are then carefully covered with sugar, to which a pleasant pink colour (*coccus cacti*) is given, and they then look like very pretty sugar-plums.

To these saccharated capsules the name of Copahine-Mège was given, because the experiments had been made conjointly by M. Jozeau and M. Mège, and the latter had first thought of making the saccharated capsules. For lymphatic patients and delicate females a second mass was prepared, into which, besides the above-mentioned ingredients, some steel was made to enter. This is then a sort of martial preparation of copaiba. The doses are stated as follows:—

When there is neither pain nor inflammation, five saccharated capsules are taken three times per diem. One capsule more is then given with each dose every subsequent day, the doses being thus increased until purging is produced. Where there is pain or inflammation, these should first be treated by the surgeon in the manner he thinks the most advisable, and the copahine is to be commenced when acute symptoms have abated. It has been noticed that the martial capsules have effected a cure when the simple preparation has failed.

Such being the explanations given by M. Jozeau, several hospital surgeons agreed to give the capsules a trial; but this proved somewhat difficult, as far as public practice is concerned, since persons affected with gonorrhœa are not in general admitted as in-patients into these institutions. It was, moreover, evident that upon out-patients the effects could not be so conveniently watched, and the value of the remedial agent ascertained. We here subjoin some of the results obtained:—

## CASES AT ST. BARTHOLOMEW'S HOSPITAL.

John B., aged twenty-eight, has had gonorrhœa four days, and has not tried any remedies. He commenced taking the capsules October 17th, 1851, the dose being five of these thrice a day. Six days afterwards, there was no improvement; bowels open regularly twice a day; no nausea, but slight scalding in passing urine. Take six

capsules three times a day. Two days after this increase of the dose, the patient was found better; the discharge had considerably lessened, the scalding had ceased, and the bowels were opened three or four times daily. No nausea. Take seven capsules three times a day.

October 30th, thirteen days after the commencement of the treatment, the discharge had nearly ceased. Bowels open four times a day. Take twenty-four capsules per diem. Five days after this, the discharge had entirely disappeared. On Nov. 9th, being four days after the complete cessation of the discharge, the latter slightly recurred. The capsules were resumed, and in four days, no appearance of the affection was left.

Edward L., aged eighteen. Gonorrhœa three days; a small sore on the prepuce. Commenced taking five capsules three times a day, on October 17th, 1851, and continued using them for six days, when he was taking twenty-one per diem. The patient was soon purged three times a day, and the bowels continued freely open several times daily, until the eighth day of the treatment, when the discharge ceased. There was no nausea during the use of the capsules.

Sarah A., aged twenty, has been affected with gonorrhœa for one week. She began to take five capsules three times daily, on the 17th of October, 1851, and continued them for four days, increasing the dose to twenty-four per diem, when the discharge entirely ceased. On November the 10th she left the hospital quite cured. After using the capsules for two or three days, the bowels were freely acted upon, but no nausea or sickness ever occurred during their use.

#### CASES AT GUY'S HOSPITAL.

A. B., gonorrhœa for the first time; duration three weeks; inflammatory symptoms subsiding. Patient took the capsules for sixteen days, increasing from five, three times a day, to eight, and became completely well.

W. H., gonorrhœa for the third time; discharge profuse. Took the capsules for four days, and left off from a dislike to the mode of taking the drug, ■ he allowed the sugar to melt away too completely before swallowing, and therefore experienced the unpleasant taste of the copaiba in the mouth.

Male patient; gonorrhœa three weeks. Took the capsules for a week, without any trouble; but having slightly improved, he did not present himself again.

W. B., gonorrhœa for the second time; copious discharge, which had lasted ten weeks. Took the capsules with a little inconvenience, increasing from five to ten three times daily. The drug acted very well, there was slight purging, and the discharge was checked. In this patient the capsules were not continued long enough after the discharge had ceased, for it returned to a certain extent.

Male patient; gonorrhœa second time; copious discharge. Took the capsules, from five to twelve, three times daily, for eight days, without any effect, and did not continue them. It should be noticed that no injections were used in any of the foregoing cases.

#### CASES AT ST. THOMAS'S HOSPITAL.

Mr. Clark has treated three patients affected with gonorrhœa with the Copabine-Mège capsules. The effect has generally been favourable for the time they continued taking them; but, as stated above, the treatment was not submitted to with sufficient regularity to follow up the cases in a completely satisfactory manner. No vomiting, eructation, or unpleasant gastric symptoms occurred in any of the cases.—*Lancet*.

HEALTH OF THE TROOPS ON THE INDIAN STRAITS.—At Sullundhur, sickness is very prevalent amongst the 60th Rifles, there being 166 in hospital. At Meean Meer, upwards of 140 of the 96th Regt. are on the sick-list. In Umballah, the 75th lost by cholera in seven days, nineteen men, six women, and as many children. The Artillery and Lancers are also sufferers.

#### REVIEWS AND NOTICES OF BOOKS.

ON RHEUMATISM, RHEUMATIC GOUT, AND SCIATICA; their Pathology, Symptoms, and Treatment. By HENRY W. FULLER, M.D., Cantab., Fellow of the Royal College of Physicians, London, Assistant-Physician to St. George's Hospital, &c. &c. London. 1852. 8vo. pp. 403.

THE author, in the preface to the volume before us, says that he had "proposed to himself to commence the present treatise by a record of all that has been ascertained of the history of Rheumatism; and by reference to the facts thus proved and established, to show how conflicting opinions may be reconciled, and the pathology and treatment of the disease elucidated." But too many obstacles presented themselves; he therefore commences by an "exposition of his own views of the disorder." The volume consists of an introductory and twelve other chapters; the first five are devoted to acute rheumatism; the four succeeding chapters to rheumatic inflammation of the heart. We have next a chapter upon the other complications of acute rheumatism; and the three last are devoted respectively to rheumatic gout, chronic rheumatism, and sciatica.

Dr. Fuller commences by combating the generally received opinion, that the immediate cause of acute rheumatism is exposure to cold and moisture; he adduces many arguments in support of the opinion that acute rheumatism is the result of the presence of a morbid matter in the blood, and that cold and moisture merely act as predisposing causes. He next considers the rheumatic diathesis, and the causes which influence its development. Among the circumstances which favour this, he attaches some importance to hereditary predisposition, "Among the rheumatic patients admitted into St. George's Hospital, nearly 29 per cent., he says, inherited the predisposition from either parent."

The next chapter is upon the seat and classification of rheumatism. The author describes four forms—viz., acute rheumatism or rheumatic fever; 2nd, rheumatic gout; 3rd, chronic rheumatism; and 4th, neuralgic rheumatism. We have then a description of acute rheumatism, its various modes of attack, its symptoms, general and local, and its complications. The treatment of acute rheumatism occupies the next chapter; after some remarks upon the various remedies which have been employed in it, and upon the uncertainty and contrariety of the remedial measures hitherto adopted, Dr. Fuller treats, in succession, of the following remedies:—"Bleeding, purging, opium, vapour and hot-air baths, mercury, tartar emetic, cinchona, guaiacum, colchicum, nitrate of potash, lemon-juice, and alkalies and their salts." Two of these substances—viz., nitrate of potash and lemon-juice—have been highly spoken of, and extensively employed within the last few years in acute rheumatism; the author has tested each of them in a certain number of cases of the disease, and we shall quote his experience respecting them.

"M. Gendrin in France, and Dr. Basham in this country, have lately been adopting the practice recommended by Dr. Brocklesby in 1764, of giving large and repeated doses of nitrate of potash. Dr. H. Bennett speaks most favourably of its efficacy, as administered by M. Gendrin at the hospital of La Pitié. He states that the salt when properly administered, is from the first tolerated in the great majority of cases. . . . Dr. Basham also speaks highly of its value when freely administered. One, two, or even three ounces of it freely diluted may, he says, be taken in the twenty-four hours in cases of acute rheumatism, and in the majority of cases without producing any obvious effect on the force or frequency of the pulse, the integrity of the digestive function, or even upon the quantity of urine excreted; but it relieves in a marked manner the swelling, heat, and pain of the joints. He has never seen the nitrate of potash, in large or small doses, produce either nausea or vomiting.

Now, I heartily wish I could confirm this favourable report of the curative action of nitrate of potash, but such unfortunately is not the case. I have watched its administration to the extent of about an ounce daily, in seventeen cases of acute rheumatism, and to a smaller extent in several others, and in

one instance only did it appear to exercise any decided control over the course or duration of the symptoms. In most instances it was readily tolerated by the stomach; and in the case alluded to, gave rise to, copious diuresis, with manifest relief to the pain and inflammation; but in every other instance it was without any obvious effect upon the excretions, and the disease continued of average intensity, and ran on to its ordinary duration."

Lemon-juice as a cure for rheumatism, was introduced by Dr. Owen Rees: "he supposed that, by the excess of oxygen it contains, it promotes the conversion of lithic acid into urea and carbonic acid, and thereby favours its excretion from the system, while the small quantity of alkaline citrate which it contains contributes also in some measure towards effecting a cure." "Whatever its mode of action, however, the remedy (Dr. Fuller observes) had the advantage both of simplicity and novelty, and accordingly for some time was very generally adopted. But after an ample trial it has now been discarded as uncertain in its action, and physicians are again content to rely upon a more rational, though more complex method of treatment."

"The advantages claimed for this remedy by Dr. Owen Rees are, power to moderate vesicular action, and to afford speedy relief to the rheumatic symptoms. Judging, however, from my limited experience, I cannot conscientiously speak of these effects as the ordinary results of its administration. I have watched its exhibition in twenty-two patients, and although in several it produced much depression, in some griping pains in the abdomen, and in one gave rise to violent diarrhoea, accompanied by a copious discharge of blood from the bowels, yet in three patients only did it appear to afford relief, or to hasten recovery."

In the three instances alluded to, it was taken in full doses; viz., eight ounces in the twenty-four hours; and was not only tolerated, but, as far as I could judge, was speedily converted or assimilated in the stomach, and its influence in quieting the heart's action, in promoting a free evacuation from the kidneys, and in causing subsidence of the articular inflammation, was very marked. But in most cases it did not appear to be readily converted in the stomach, as was evidenced by the length of time which elapsed before the patient became free from its flavour; and this perhaps may account for its frequent failure in alleviating the symptoms of the disease. Be this as it may, the results of its administration were anything but encouraging."

Rheumatic inflammation of the heart next occupies the author's attention. The chapters upon this complication of acute rheumatism, which extend to upwards of 120 pages, are among the best in the volume. "The space allotted to those diseases of the heart which arise so frequently in connexion with rheumatism, may, at first sight (Dr. Fuller observes), appear unnecessarily large; but the importance of these affections cannot be over-estimated. They may complicate and render formidable the simplest case of rheumatism, and may affect the future as well as the present safety of the patient; moreover, they are the very points on which the student is most in need of instruction and advice." "Their incursion is often (he adds) insidious, their progress rapid, and he who is not well informed on all that relates to their symptoms and treatment, may often overlook their existence, and fail to avert their most dangerous consequences." "I have, therefore, been unwilling (the author observes) to omit anything which may lead to a just estimate of their importance, to a full understanding of their physical signs and symptoms, and to a due appreciation of the various grounds on which their treatment should be based."

We regret that our limits will not permit of our making any extracts from these or the succeeding chapters; we cannot conclude, however, without expressing a favourable opinion of the treatise. The author's position, as physician to a large hospital, gave him opportunities for investigating and treating the disease upon a large scale, and he appears to have fully availed himself of those advantages. His matter is well arranged, his descriptions are clear, his views respecting the disease appear to be sound, and his treatment to be judicious and practical.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, NOVEMBER 24, 1852.

### THE MEDICAL CHARITIES.

In another column we print a series of resolutions adopted respecting this measure at a meeting of the medical men of the counties of Limerick and Tipperary, and it is therefore unnecessary to repeat here what is there so clearly expressed as to the objects contemplated. All we have to do is, to inquire and suggest in relation to the matter; for to offer special advice at such a stage of the proceedings would be an exercise of authority which we could not be justified in assuming. As we have lately hinted, we counsel deliberation and inquiry, to enable our friends to see their way clearly before they commence operations; and in the first place, to consider well the state of the law as it stands relative to the powers conferred on either the Commissioners or Guardians as to the settlement of salaries. Looking at the Act of last year (clause 8), it appears as if no doubt could be entertained on the subject; but we hear that reading it in connexion with the Poor-law Act, and its numerous amendments, and viewing it as affected by previous practice, the matter is not so unquestionable. By this clause the Guardians are empowered to "determine" the salaries, "subject to the approval of the Commissioners," and the Commissioners are empowered to "regulate the amount of salaries," which seems to us, unlearned in the law, plain enough; but let the proceedings of the two parties become conflicting, and the lawyers may make it otherwise. Here, then, is a tangible point for discussion and settlement. If the Guardians "determine" to give an inadequate salary to a Dispensary Surgeon, can the Commissioners compel them to give an adequate one? Then, if they can compel them, it may be well to inquire whether the means at their disposal enable them to do so without such a collision as may lead to serious interruption of amicable relations between the parties. In fact, the same question arises as that between the old Dispensary Governors and the Grand Jurors regarding the power to refuse presentments. The law, if we recollect it rightly, laid down that the Grand Jurors might, and should, and were required to present; but still they, we believe, in certain cases refused, and the Judge did not over-rule their decisions. It is obvious that the question involves the important principle of a taxation by others than the representatives of ratepayers; but then we conclude that such a method of taxation has been sanctioned in other cases. We, however, put the question, because we hear that some Board of Guardians, and we believe in the county Limerick too, has questioned the powers of the Commissioners in this behalf, and even refused to obey their orders to alter the amount of salary. Is this so, or are we misinformed? At all events, if any doubts exist as to this most important point, the sooner they are settled the better; and therefore the sooner the proposed Association applies itself to it, the sooner it will be removed. Doubtless, a legislative provision to settle the matter by declaring that the lowest salary given should be £100 a year, would be most desirable, and every effort should be made to obtain it; keeping in view the advice given at the end of our London correspondent's letter this day, that half should be paid by the ratepayers and half from the Consolidated Fund. In the meantime, while these pro-

ceedings are in progress, other resources should not be neglected. As we have already suggested, a local influence should be brought to bear on local authorities; and appeals should be made to that sense of justice which cannot be entirely dormant even in the lowest grades of society. The most sordid brute that ever sat at a union board will be found sensitive to reproach if it be distinctly directed against him personally. Such fellows are obdurate only when they can shift the responsibility from their own shoulders. It is very well to remind the Commissioners of their obligations, and especially the *ex-officio* Commissioners, who have great government and parliamentary influence, but it is equally important that the Guardians, Ratepayers, and Dispensary Committees should be taught their duty. Why not have a well-drawn up appeal to such parties, prepared and transmitted to every one of them in every union in Ireland. In no other way can instruction on this point reach them; for the newspaper press is too much under control of subscribers to venture on energetic remonstrance.

### MEDICAL DEGREES—LONDON UNIVERSITY.

WHILE we deplore the degradation of the title of Doctor of Medicine, in consequence of the perversion of Colleges and Universities to purposes foreign to their legitimate destination, it is some consolation to find that one at least can be discovered having better objects in view, as appears from the following:—

At the time of its foundation, the University of London initiated a plan of examination before unknown in this country, or at least unpractised by the various medical Examining Boards. A most important feature of the elaborate scheme drawn up by the Senate was the combination of practical tests with the usual oral and written examinations. To insist upon the advantages of testing the practical knowledge in anatomy, botany, *materia medica*, and chemistry, of a man about to engage in the daily practice of applying the resources drawn from the three kingdoms of nature, and variously operated upon in the laboratories of the chemist and the human frame, for the alleviation of disease, now appears to be a superfluous task. But at the time when the metropolitan University was founded, those advantages were disregarded, or the feasibility of subjecting candidates to tests of this nature was denied. The experience of the University has proved how feasible is the task, and the high reputation which the London medical degree has attained places its utility on no doubtful ground. The example has, indeed, since been imitated with success. While the ancient Universities have recognized the value of the example set them by their younger sister, by extending their narrow circle of instruction and examination, so as better to represent the enlarged circumference of modern knowledge, and the increased requirements of a progressive age, the medical corporations have on their part adopted, to some extent, the innovations made by the Senate of the University of London upon the time-honoured system of conducting the examination of candidates for medical practice. The College of Surgeons, in framing the scheme of examination for the higher order of fellows, made it necessary to investigate the practical acquaintance of the candidates in anatomy. From the commencement of the examinations for the degree of M.B., in the University of London, it has been the custom to call upon the candidate to dissect in the presence of the examiners, to demonstrate anatomical preparations, to describe specimens of living plants, to designate specimens from the *materia medica*, and to conduct some elementary chemical analysis; and the candidate for the Doctor's degree has been required to give a minute commentary upon a medical case. The system has worked well. Candidates preparing for the University examinations find it necessary to acquire something more than book-learning. For the Colleges, for the Apothecaries' Hall, students still derive the most comfortable assistance from the "grinder." Men aspiring to the University degrees, resort to the fields, to the museums, to the dissecting-room, to the laboratory, to the clinical wards, as the indispensable means of success. Notwithstanding a re-

commendation made some time ago by the Examiner in Chemistry, prompted, we fear, more by indolence than by any other motive, to discontinue the practical examination in chemistry, the Senate wisely resolved to accede to no infraction of their fundamental principle. They have recently given fresh proof of their faith by carrying out still further the system of practical examination. At the second examination for the degree of M.B., just concluded, the candidates were required to name and describe microscopic specimens. In surgery they were examined by demonstrations from wet and dry preparations, illustrative of various surgical diseases and accidents, and of their treatment. The examiners in medicine required the candidates to examine patients in the wards of a metropolitan hospital, and afterwards to report in writing on the cases. It must be obvious that none but those extensively and practically conversant with the entire range of medical knowledge, and with disease at the bedside, could come out successfully from an ordeal so practical; nor can it be disputed that a man who has come out successfully has established his qualifications for the practical duties of his profession in the most unimpeachable manner. Some persons we know there are, who, with little consistency, and we fear with little candour, have been accustomed to contrast the examinations of the University of London with those of the colleges, by admitting the superior theoretical or speculative merits of the former, and implying that the special merit of the latter is their essentially practical character. How can we separate the theoretical from the practical in medicine? All practical knowledge is based upon some theory. Rightly understood, the theory of medicine is accurate knowledge of the elementary sciences upon which medicine is constructed. Those whose duty it is to introduce to the community men possessed of sound practical knowledge, must take care that the theory is good. This they can secure by extensive examination in the elementary branches of medicine, which are the only safe basis for rules of practice. If they neglect this, they will run the risk of stamping a mere empiric. We cordially thank the Senate of the University of London for this new step in their progressive extension of the system of practical examinations. We are well assured that it will tend still further to augment the credit and the value of the degrees they confer, and to establish the scientific position of medicine.—*Lancet*.

### MEDICAL LIFE IN LONDON.

#### POOR-LAW APPOINTMENTS.

London, November 10, 1852.

COINCIDENT with the opening of Parliament, our King, Lords, and Commons in Berner's-street, commenced the campaign of the Medical Societies this week, with promise of a busy session. Mr. Cæsar Hawkins, on the part of the College, has been to the Government. Sir P. Crampton has arrived professionally in England, and the Duke of Wellington's funeral will not fail to bring more of your "medico's." Would that they could attract the ear of those in authority, like Cæsar Hawkins, and that a better understanding arose as to your medical charity appointments: in the interest of which the MEDICAL PRESS has long laboured with such assiduity and success. Ireland herself (as well and practically alluded to at the opening of the session of the College of Surgeons) is looking up out of the ashes and sackcloth where the political economists would place her. The Schools of Medicine must, also, feel shortly the vitalizing influence of the golden treasures of what Alison calls the "fifth hemisphere" of the world. The late earthquake may have been the facetious result of some of our ophthalmological or other discoveries, and will pass off. Medical affairs come round, and the profession regains its old saturnian reign of respectability and success. We are not going to chronicle the doings of the "Medico-Chirurgical" in Berner's-street; the papers read on Tuesday night, and every fortnightly Tuesday to come of the season, you will find of course in the ordinary channels of information, as we must complimentarily call our weekly journals here. A more practical subject far seems this of your medical charities and salaries.

The chief source of error at present in apportioning the salaries of medical men in Ireland under the new Medical

Charities Act, arises from Government at this side of the water estimating the Dublin surgeon as such another "professional" as the English poor-law surgeon. There are many good and valuable men among the English poor-law surgeons, but the mass of poor-law country practitioners in England are uneducated, and without any professional standing of any apponable shape or quantity, whatever: complete tradesmen, with little huxters' shops, soda water, soaps, scented oils, and the heraldic emblems of the College diploma, making up a show to astonish the bucolic imagination. The position of the two men (the English and Irish parish doctor) are of course alike; but the education and standing of the Irish surgeon are quite and entirely superior. The difference is as great (it should be made known to the Castle authorities) as the difference in respectability between an assistant-barrister at quarter sessions in Ireland and an assistant-attorney, we will say, at a south-western inquest. We never knew but one Dublin literary man to dispute the point. In an English parish, a rule, every one is able to pay a doctor, and it is only the poorest who apply for medicine. A parish doctor here will take an immense district for £10 or £15, for the sole purpose of keeping out another practitioner; and good, easy, large-boned, rural guardians will make it a precedent for a whole side of a country that the thing is to be done for £10 or £15 by the man with the strongest shop.

In town districts, where the Fates are more propitious, we have known men get £150 a year for doing nothing at all, half a guinea for each midwifery case, and two or three guineas, as the case may be, for the minor operations of surgery—dislocations, simple fractures, &c. The redundant population, about Temple-bar and Lincoln's-inn-square for instance, are assisted by more than one or two members of the College in their parturient throes, at sums varying from £120 to £180 a year each; an undescribed animal in the vestiges of creation scale called an "assistant" doing all the work for nothing. The *Lancet* has been telling us of an assistant who ran away from his master on account of the latter trumping up a fictitious practice in his ledger and day-book; perhaps we might put on record (preserve as a fly in amber) the sayings and doings of another of the class whom we incidentally fell in with lately in the library of the College of Surgeons. The gentleman is well educated, is now partner in an establishment not ten minutes walk from Westminster Abbey, but had arranged to act in capacity of assistant in one of the districts before mentioned. Monthly medical tea parties, it seems, are held to play cribbage and epidemiologils; everything going on well; tall fellows of the College in white solemn neck ties; Mr. Highley, bookseller to the College; one or two M.D.'s; a sprinkling of Bartholomew's men: all come together with every new moon, full of sanitary discoveries and the last gossip of the Lord Mayor's dinners; our poor friend introduces himself to the solemn assembly; he had met great men before (the Agamemnons of Fleet-street) the poor fellow stated to us; but then they were only country baronets and lords; and he had played a quiet "rubber" with Lord This, and taken coffee with Lady Blanche the other, and had his run dozens of times with the hounds, as any gentleman; the man, in other words, was superior to every one of the lot, but then it was not every day an "assistant," though a member of the College, could expect the edifying greatness of the St. Bride's and St. Dunstan's wise men of the east. It was arranged by the surgeon's wife that he would answer; it was impossible to say but with a little polishing and getting-up he might finally arrive at such professional advancement as to be able to sell tooth brushes and hair oil as gracefully as if he was paid for it; indeed, it was not easy to say, this lady assured him, what early rising and unremitting toil, from six o'clock in the morning till only twelve at night, might not do. Money was a secondary consideration to the splendid midwifery and

other practice all round the classic precincts of the Temple; the palace of Henry VIII., where he could have his hair cut gratis for nothing among the patients; but *surgit amara aliquid*, the moral of our tale is in the little fragment of bitterness behind. The surgeon's wife, who was master of the shop, thought she would let her happy victim know the entire number of his privileges; the entire poor-law duties were to devolve on him, to which respectable breaking of stones on a public road (we would say in a parenthesis) would be a luxury. In the intervals of attending midwifery and scarlatina in the filthy dens bordering on Saffron-hill, Holborn, and the "ooze of the salt deep" about the Temple, he was to make pill masses and horse balls. "You are an early riser, of course," said this engaging creature with one of her blandest smiles—the poor fellow thought of his friends in the country: we can fancy him even cursing the day that brought him within the precincts of the College of Surgeons at all—"you will be called up at night, of course; but that you are accustomed to." He thought of the vast privileges of monthly tea parties on sanitary reform, though some of the worthy fellows of the College did sell hair oil and tooth brushes, but had white ties. "There is only one other little thing I would just mention: you dust and sweep the shop every morning; and of course take down the shutters." The poor fellow, who is a Welshman, wished the woman some direful curse, all in Welsh consonants (ll's and w's), and wished her a good morning. Yet this man and his master (mistress) are a type of the class on a level with which are now placed the educated Dublin surgeon. If we have had any object more prominent than another in these "jottings" of London medical life, it has been of a practical character, to show the difference between the London and Dublin surgeon. Beautiful as Truth itself, mild and beneficent—we had almost said sacred—becomes the practice of the medical man in his every-day ministrations among the sick; if his rule of conduct be purely professional, if, with that chiefest of Christian maxims, to do unto others as we would they should do unto us, we join a masculine endeavour to do only what is right, and true, and kindly, then indeed is he fulfilling his part as much as in knowing the latest discovery or learning the newest mode of diagnosis. If he becomes, however, once a mere tradesman, all the instincts of London surgery invariably tend, his position day by day with the public becomes worse and worse. Government, as now actually occurs, values him at his own figure, or rather the figure put upon him by his college; his college simply grasps the guineas. No gentlemanlike education is expected from him; the man who was a poor chemist before 1815 has money to buy a fellowship, and asks him to sweep the shop. The London surgeon sweeps the shop, and the London penny-postman holds his nose and passes on. The London surgeon sings at the tavern; the London surgeon in dozens enlist in the police; yea, verily, the very boys in the street cry out the London surgeon is a curiosity.

One is tempted to write this more in grief than anger: that a profession, second to no other in its social position—a profession which should be marked out by all that is noble, generous, and good, should every day, from the cupidity of diploma sellers, become a by-word and a scoffing.

A poor fellow has been lately bitten by a *cobra di capello* in London—the cure all over the world is a stimulant—the man died in agony in almost a few minutes; the public wait with breathless suspense for some member of the College of Physicians or Surgeons to give some hint on the matter, but in default of anything better, the *Times* gives a mortal column of rubbish from one of the leaders of the homœopathic school that the cure most likely to prove of use would be to bite back the man to life by another snake; that one snake antidotes a second, *argal*, though a bottle of simple brandy would have cured him, the opportunity of testing the wisdom of the profound Hahnemann should not have been lost. It is

At about three o'clock, the chair was taken by the President, Dr. Boxwell, the minutes of the first meeting, with the list of the officers for the ensuing year, being read by the Secretary, Dr. Cranfield, and confirmed by the signature of the chairman. After the enrolment of several new members, apologies were read from

many who could not conveniently attend, owing to various causes. There was one from Dr. Carton of Oulart, calling the attention of the society to the inadequate sum allowed for medical attendance on the constabulary, particularly in the country districts, where stations were situated so far from the medical officer's residence. The subject was taken up very warmly; and it was suggested by many that the attendance ought to be resigned, as not at all remunerative, the medical man being exposed to be called on at unreasonable hours to the different localities for such a small sum as was given. However, ultimately, the further consideration of the matter was adjourned to the next quarterly meeting, to be held at Enniscorthy, due notice to be given previously to each member of the society.

Dr. Boxwell introduced the subject of medical men being called on to attend inquests out of their own districts, contrary to the provisions of the Coroners' Act. He read a correspondence which took place between Dr. Furlong and Mr. Hawkshaw, coroner for the south division of the county, in which the latter explained at some length the cause of the complaints made by Dr. Furlong, which appeared satisfactory to the meeting. The Secretary was requested to thank Mr. Hawkshaw on behalf the society for his courteous and gentlemanly conduct, also to thank the county inspector, Mr. Colclough, with whom Drs. Boxwell and Furlong had an interview, in consequence of some interference on the part of some constabulary who outstepped their duty with respect to some recent inquests. The county inspector promised that he would take care they should not do so again, and that he would draw the attention of non-interference in these matters to the different members of the force through the county.

A circular was agreed on, to be sent to each member of the profession in the county, calling attention to the sections in the Coroners' Act, that no medical man ought to attend an inquest in another's district except under some peculiar circumstance, such as absence from the district of the resident, or that a second opinion was needed; as such is often required when something doubtful may occur that the attendance of two medical men is necessary, say in criminal prosecutions, or cases where a satisfactory result may not be come to.

After the discussion of various matters connected with the interests of the profession—say dispensary districts, their practice and attendance—amidst the most perfect harmony the meeting adjourned.

The members dined together, and spent a most happy evening, looking forward with satisfaction to their next assembling at Enniscorthy.

To CORRESPONDENTS.—The letter of "A Constant Reader" is in type: it will appear in next number.

#### THE MEDICAL CHARITIES.

At a most numerous and influential Meeting of the Medical Men of the Counties of Limerick and Tipperary, held at Boyton's Hotel, in Thurles, on the 13th of November, as convened by Circular of the 30th ult., it was unanimously resolved that

JOHN RYAN, Esq., M.D., take the Chair.

It was also unanimously resolved that Dr. Benjamin W. Bradshaw be appointed Secretary and Treasurer.

Proposed by Dr. John Dwyer of Cappawhite; seconded by Dr. John A. Powell of Roscrea—

"That an Association be formed, to be called THE TIPPERARY MEDICAL ASSOCIATION, for the protection of the rights and interests of the Medical Profession, and the taking into consideration any question which might arise either between medical gentlemen or between the latter and the public, which may in any way tend to compromise the honour of the Medical Profession."

Proposed by Dr. M. J. Quinlan; seconded by Dr. B. Mullally—

"That the medical gentlemen of every county in Ireland be requested to form a similar association, for the purpose of co-operating with this and similar associations already formed."

Proposed by Dr. James Heffernan; seconded by Dr. John Ryan of Pallas—

"That in compliance with the suggestion of Dr. Kingsley of Roscrea, a General Meeting of the Medical Profession be held in Dublin early in January, 1853, at which a deputation from each Medical Association in Ireland is earnestly requested to attend."

Proposed by Dr. T. J. Morrissey; seconded by Dr. John Russell—

"That the Council of the Royal College of Surgeons in Ireland, be respectfully requested to use their legitimate and high influence in the furtherance of the objects of this Association, and that we leave to them the naming of the day for calling the General Meeting of the Profession in Dublin."

Proposed by Dr. Stokes; seconded by Dr. Geo. Bradshaw—

"Resolved—That in the most trying times, when fearful epidemics raged through the land, such as malignant Fever and Cholera, the Members of the Medical Profession were, at all times, found at their post; that the mortality among them was very great—in fact, a perfect decimation; that in those bad times they struggled through in hopes that, under the Medical Charities Act, sufficient security would be afforded them; that they would obtain adequate or respectable remuneration for their arduous services; that now, although a greater amount of work is imposed on them, the salary offered is not more than sufficient to keep a servant and horse, and, in some instances, from the extent and size of the district, a second is indispensable to perform the work required from the Medical Officers; that the lowest sum which ought to be offered to a medical man is £100 a year."

Proposed by Dr. Noble Seward; seconded Dr. George Bradshaw—

"That each member be expected to contribute the sum of Ten Shillings annually, for the purpose of defraying any expenses which may be incurred in carrying out the objects of this Association, and that all subscriptions be paid in to the treasurer, before the 1st of January, 1853."

It was unanimously resolved—"That the marked and grateful thanks of this meeting be tendered to Dr. Kingsley of Roscrea (whose unavoidable absence is deeply regretted, and whose able suggestions we have availed ourselves of), for the benevolent and philanthropic manner he has, at all times, come forward to support and forward the welfare of the profession."

Resolved—"That those Resolutions be inserted, for one post each, in the MEDICAL PRESS, and also in the *Dublin Evening Mail and Freeman's Journal*."

JOHN RYAN, M.D., Chairman.

Resolved—"That Dr. M. J. Quinlan be called to the second chair."

It was unanimously resolved—"That the best and most marked thanks of this meeting be given to Dr. Ryan for his dignified and urbane conduct, not only on this, but at all times when called on to lend his aid in advancing the interests of the profession."

M. J. QUINLAN, M.D.

**SCHOOL OF SURGERY.**

**ROYAL COLLEGE OF SURGEONS.**

**NOTICE TO STUDENTS.**

CERTIFICATES of Attendance on the Lectures and Demonstrations of the Winter Session are not received as qualification for the Letters Testimonial of the College, unless such attendance shall have commenced on or before the 25th day of November.

Absent Students are therefore informed that, unless they be present and Enrolled on or before Thursday next, they cannot be returned as Pupils for the present year.

**CORK SCHOOL OF MEDICINE.**

The Twenty-sixth Winter Session commenced on the 22nd instant, at Two o'clock p.m.

Anatomy and Physiology—H. A. Cæsar, M.D.

Surgery—W. K. Tanner, M.D.

Materia Medica—J. F. McEvers, M.D.

Botany—T. Power, M.D.

Midwifery—W. C. Townsend, M.D.

Practice of Medicine—C. Y. Haines, M.D.

Chemistry—W. C. Nash, M.D.

Natural History—T. C. Shinkwin, M.R.C.S.

Natural Philosophy—Ed. McCarthy, Esq.

Practical Anatomy—H. A. Cæsar, M.D., T.C. Shinkwin, M.R.C.S., and E. Lundy, M.R.C.S. Eng.

This School, situate on the South Mall, midway between the North and South Infirmaries, has all the requisites for a complete Medical Education. Its reputation, for over a quarter of a century, is best tested by the high character of its numerous "Alumni," not only in this city and province, but in each department of Her Majesty's Service, and every quarter of the globe.

DISSECTIONS HAVE COMMENCED.

For particulars apply to Dr. Cæsar, South Mall.

October 12, 1852.

**THE ROYAL EXCHANGE ASSURANCE,**

*Incorporated A.D. 1720, by Charter of George the First.*

THOMAS TROUTON, AGENT,

No. 8, WESTMORLAND-STREET, DUBLIN.

Fire and Marine Assurances on liberal terms.

Life Assurances with Bonus (which has averaged 43 per cent. on the Premium); or, at lower rates, without Bonus. Moderate Premiums and a fair division of Surplus.

Age.	With Profit.	Age.	Without Profit.
	£ s. d.		£ s. d.
20	2 0 11	20	1 17 6
30	2 11 7	30	2 7 8
40	3 6 3	40	3 1 9
50	4 11 3	50	4 5 8

Exemption by the Charter from the liabilities of Partnership. The Security of a large Capital Stock, and the moral guarantee afforded by 131 years' experience and reputation.

The soundness of a thoroughly tested Office, with all the real improvements of modern practice.

THOMAS TROUTON, AGENT,

(Successor to Richard Purdy.)

No. 8, WESTMORLAND-STREET, DUBLIN.

**BARON LIEBIG ON PALE ALES.**

If I wished to associate with any individual brewery my remarks on the alleged adulteration of bitter beer with strychnine, it would have been only natural to have mentioned another brewery, in which alone, and not in Mr. Allsopp's, I was engaged in investigating the Burton mode of brewing; and it was also in that brewery, and not in Mr. Allsopp's, that the Bavarian brewers acquired all the instructions they obtained at Burton. The admiration I expressed of this beverage, in my letter to Mr. Allsopp, advertised in such a manner as to lead to the inference that my praise was exclusively confined to Mr. Allsopp's beer; this was not the case; my remarks referred to that class of beer.

JUSTUS LIEBIG.

Giessen, July 24, 1852.

N.B. The Baron's original letter is in the hands of Mr. Miller, at the Jerusalem Coffee-house, Cornhill, where it may be seen by any one taking an interest in the matter

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

**THE COMPOUNDING DEPARTMENT AT**

**G. O. AND CO.'S MEDICAL ESTABLISHMENT**

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

**BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.**

G. O. and Co. continue to be supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

**TO SURGEONS, DISPENSING CHEMISTS, ETC.**

SULPHATE of QUININE, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, capsules, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.

October 23, 1852.

**SHIRTS CUT BY MACHINERY.**

**WEBB AND CO.'S**

New System of Shirt-cutting by Machinery enables them to produce really First-class Shirts at prices lower than they have ever yet been offered.

Their Eglinton Shirts,

at 2s. 6d., 3s. 6d., and 4s. 6d. each,

are accurately Cut, elegant in Design, and perfectly sound in Fabric.

A large assortment of Fancy Veined Full-dress Shirts always on hand.

**THE TAILORING AND GENERAL OUTFITTING WAREROOMS**

are now most extensively supplied with every description of WINTER CLOTHING.

**THE READY-MADE DEPARTMENT**

contains an immense variety of

Top Coats, Travelling Coats, Wrapper Coats, Pilot and Frieze Pea Coats,

at 15s., 17s. 6d., and 20s. each,

which, for Workmanship and Solid Value, are not and cannot be surpassed.

WEBB AND CO.,

10, 11, and 12, CORN-MARKET.

## SCHOOL OF SURGERY.

## ROYAL COLLEGE OF SURGEONS IN IRELAND.

WINTER SESSION 1852-53.

The Dissecting-rooms opened on the 1st of October, and the Lectures commenced on the 25th.

Anatomy and Physiology—Dr. Jacob.  
 Descriptive Anatomy—Dr. Hart and Dr. Power.  
 Surgery—Mr. Porter and Mr. Hargrave.  
 Practice of Medicine—Dr. Benson.  
 Chemistry—Dr. Barker.  
 Midwifery—Dr. Beatty.  
 Comparative Anatomy—Dr. Jacob.  
 Dissections by the Professors of Anatomy and the Demonstrators—Dr. Leeson, Mr. T. D. Hargrave, Mr. Malcomson, and Mr. J. Morgan.

## SUMMER SESSION.

Materia Medica—Mr. Williams.  
 Medical Jurisprudence—Dr. Geoghegan.  
 Botany—Dr. A. Mitchell.  
 Practical Chemistry—Dr. Barker.

*The fee for each of the above Courses is two guineas, except Comparative Anatomy, which is free.*

A public course of lectures on Comparative Anatomy and Zoology, free to all students, is delivered by the Professor of Anatomy and Physiology at the commencement of the session, and additional lectures on the same subject at intervals during the winter.

Practical instruction in Operative Surgery is given by the Professors of Surgery, separate from the surgical lectures. Fee, £5 5s.

The Professor of Chemistry receives operating pupils into the Chemical Laboratory.

The following Ordinance was made by the Council of the College on the 9th of April, 1851:—"To enable surgical students to devote more time to hospital attendance and dissection during the winter session, the lectures on materia medica, medical jurisprudence, practical chemistry, and botany, shall be delivered during the summer session in the school of the College, and in the schools recognized by the College; and certificates granted subsequent to the 30th of April, 1851, shall not be received as qualification for Letters Testimonial, unless issued in conformity with this regulation." Similar regulations have been adopted by the Council of the College of Surgeons of England.

## Hours of Lecture :

Descriptive Anatomy—Twelve o'clock every day.  
 Chemistry—One o'clock, Mondays, Wednesdays, and Fridays.  
 Anatomy and Physiology—Two o'clock every day, except Monday.  
 Surgery—Three o'clock, Tuesdays, Thursdays, and Saturdays.  
 Practice of Medicine—Three o'clock, Mondays, Wednesdays, and Fridays.  
 Midwifery—Four o'clock, Tuesdays, Thursdays, and Saturdays.

Dissections from sunrise to sunset; one or more of the Demonstrators being always present to give instruction.

The Professor of Botany will commence a course of lectures on Structural and Physiological Botany in February. This course, taken in conjunction with that on Comparative Anatomy and Zoology, by the Professor of Anatomy and Physiology, constitutes the course of Natural History required by the Army Medical Board.

Pupils attending the Lectures on Midwifery and Diseases of Women and Children are admitted to the practice of a recognized midwifery hospital on payment of a fee of £4 4s.

The Professor of Medical Jurisprudence gives practical instruction in Toxicology in his Laboratory.

## DISEASES OF THE EYE.

DR. JACOB will deliver a full Course of Lectures on the Anatomy, Physiology, and Optical Mechanism of the Eye, during the ensuing Session, in the College of Surgeons, and also a separate Course on its Pathology and Diseases, with the Operations required in their Treatment, in the City of Dublin Hospital.

## CITY OF DUBLIN HOSPITAL,

Upper Baggot-street.

The Winter Session commenced on Monday, October 25.

The arrangements of this hospital are such as to afford the student an opportunity of studying disease in all its forms—Medical and Surgical. The morning visit commences daily at half-past eight o'clock, when the nature, treatment, and progress of each case are explained at the bedside of the patient, and ample opportunity afforded to every pupil of becoming practically acquainted with the uses of the Stethoscope. Clinical Lectures are delivered after the hospital visit.

Connected with the hospital is an extensive Dispensary, at which the pupils are allowed to perform the minor operations, under the guidance of the surgeons, and are rendered familiar with the details of dispensary management.

Every facility is given to students desirous of acting as Dressers and Clinical Assistants, subsequent to which all pupils of the hospital are eligible to the situation of House-Surgeon, according to merit.

A distinct course of Lectures upon Diseases of the Eye is delivered by Dr. Jacob, which the pupils are privileged to attend without additional fee, and special wards are appropriated for the reception of Eye Cases. Extended opportunities are thus afforded for acquiring a thoroughly practical knowledge of this important subject.

A ward is appropriated to the Diseases of Females, and clinical instruction is given upon all forms of Uterine Affection by Dr. Beatty.

Mr. Tufnell's course of Lectures upon Military Surgery is also open to the pupils of the hospital. This course is recognized as equivalent to six months' surgery in the professional qualification of candidates for admission into the Army, Navy, and Ordnance Medical Departments, and is required to be attended by all gentlemen entering the Hon. East India Company's Service.

A Lending Library of well-chosen books has been provided for the use of the pupils; and a correct Registry of the cases in hospital is kept by the House-Surgeon, to which they have free access.

Certificates of attendance on this hospital are recognized by all the Colleges, Universities, and Halls, and by the Army and Navy Medical Boards.

Fee for Winter six months	...	...	Six guineas.
" Summer six months	...	...	Four guineas.
" Nine months	...	...	Eight guineas.

## Medical Attendants.

- A. Jacob, M.D., Fellow and Professor of Anatomy and Physiology, Royal College of Surgeons, 23, Ely-place.
- T. E. Beatty, M.D., Fellow and Professor of Midwifery, Royal College of Surgeons, 18, Merriion-square, North.
- C. Benson, M.D., Fellow and Professor of the Practice of Medicine, Royal College of Surgeons, 34, York-street.
- W. Hargrave, M.D., Fellow and Professor of Surgery, Royal College of Surgeons, 37, York-street.
- R. C. Williams, M.D., Fellow and Professor of Materia Medica, Royal College of Surgeons, 14, Lower Fitzwilliam-street.
- T. G. Geoghegan, M.D., Fellow and Professor of Forensic Medicine, Royal College of Surgeons, 52, York-street.
- J. Tufnell, Esq., Fellow of the Royal College of Surgeons, 58, Lower Mount-street.

## Consulting Physicians.

Sir Henry Marsh, Bart., and Professor Apjohn.

## Consulting Surgeons.

Sir Philip Crampton, Bart., Professor Porter, and J. W. Cusack, M.D.

For further particulars apply to Dr. Benson, York-street.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho. Wednesday, November 24, 1852.

### MISCELLANEOUS CASES AND OBSERVATIONS IN THE PRACTICE OF MEDICINE.

By J. KIRBY, LL.D.,

Professor of the Practice of Physic in the Royal College of Surgeons, &c. &c.

#### CASES OF IRRITABLE TUMOUR OF THE BREAST.

March 18, 1822: Mrs. O'B., aged about 50, consulted me six months ago in consequence of a small tumour of the right breast, discovered by accident a few days before. The tumour was as large as a small marble, irregular, hard, moveable, and situated in the angle made by the breast as it falls to the axillary side of the nipple. The integuments were free from discoloration. Handling or motion of the arm produced but little uneasiness. The nipple was natural, and the breast in every other respect apparently healthy.

Mrs. O'B. has for several years been a sufferer from derangement of the liver, for which she has occasionally had recourse to mercury. She has sometimes had hæmorrhoids, and has been subject to attacks of diarrhoea, but in her own opinion enjoys a comfortable share of health.

Since I first saw this tumour, she has abstained from handling it, and kept it covered at first with the emplastr. hyd., but lately with the emp. saponis. She has used no other internal medicine than the ext. conii, with the pil. hyd. A moderate diet has been observed, and she has avoided exercise of the right arm.

July 26th: For the last fortnight the breast has been more uneasy, pains occasionally extending to the shoulder, affecting the arm, and prevailing over the region of the hypochondrium, which last circumstance she attributes to an attack of bile, from which she frequently suffers. There is too much reason, however, to attribute it to disease of the mamma, now larger much than the other breast, firmer, and it is more easily pained by handling; and the nipple, where she never perceived anything before, she thinks is now sometimes the seat of uneasy sensations. The axilla is free; she has become very thin, and more sallow than I

VOL. XXVIII.

ever before observed her to be; appetite bad; the original tumour is still moveable, and seems of an unaltered magnitude. Blue pill and rhubarb draught in the morning; afterwards resume the blue pill and extract of cicuta; lay aside the soap plaster, and substitute the mercurial.

She attributes the present change to more exertion of the arm than she was in the habit of making.

Dec. 16th: There was now no pain; she has continued the mercurial plaster; the tumour inconsiderable; the mamma similar to the other; she can move her arm without pain, and can lie without uneasiness or oppression on the affected side.

As the tumour was on the 16th of December, 1822, so it is at the present day, November 27, 1852 (as I am informed by her son, Dr. O'Brien), in no way altered in character, and still covered by a mercurial plaster; and this at the close of a period of thirty years.

Sir Astley Cooper, when treating of these diseases, says he has known it to continue for some years, and "once during twelve years." But the above case demonstrates that it may exist for nearly three times that period without ever displaying a malignant tendency, or requiring an operation which would be "quite unjustifiable."

This disease occurred when the lady was fifty years old, and at a time when the menses had disappeared, but she could not trace it to any exciting cause other than her highly bilious constitution.

Besides the ordinary means to regulate the action of the liver, she employed internally the extract of cicuta, to which much of her freedom from pain is perhaps attributable.

#### CASE 2.

Miss I., who is beyond 50 years old, and of an extremely nervous temperament, has been for some years very subject to intense bronchitis with recurring aphonia, from which, however, she is now free. She is tall, slender, and somewhat emaciated in consequence of the attack and the discipline necessary for its removal.

Upon some slight cause she was first attracted by a small painful tumour in the right breast, of the size and shape

of a small almond nut, which is quite close to the surface and perfectly moveable. It is placed much to the axillary side of the nipple, and seems to be a gland of the absorbent class. The armpit is free from disease, and the clavicular region is also exempt. The breast, which is very thin, is also disengaged, except a slight general enlargement, which she has observed to fluctuate with the uneasiness of her bosom. The distress is not confined to the mamma alone, it extends to the axilla and shoulder, and stretches down the arm to the elbow, wrist, hand, and fingers. The appetite is bad; her bowels are confined; the pulse is unusually quick and weak, and her water deposits a reddish sediment; she is low-spirited, very apprehensive, and easily moved to tears; the breast feels generally sore, but is not in any part discoloured.

I saw her on the 22nd of April, 1851, in conjunction with my friend Mr. Pakenham, and I ordered two leeches to be applied every second day, and a lotion containing  $\mathfrak{z}\text{i}$ . extract of belladonna to  $\mathfrak{z}\text{viii}$ . of water, to be applied in the meantime, and to be covered with gutta percha cloth. On the 5th of May, she was much annoyed by flatulence, and she required a mixture composed of cal. mag., tinct. rhei, and cinnamon water, to correct it. The lotion was continued.

Belladonna plaster was now substituted, and one was applied every fourth day; besides she had some aperient pills. On the 19th, she had opiate plaster in place of those she had hitherto applied, and on the 28th of May she took a teaspoonful of extract of sarsaparilla three times daily.

Under this treatment her health improved, the breast became less tender, and the tumour declined, so that Mr. Pakenham informed me that, as well as he can remember, it entirely disappeared, and he has not since heard anything about it.

#### CASE 3.

Miss A., aged 35, a Quaker lady, of spare and slender make, of a religious and gloomy turn of mind, and exhibiting an appearance of age far beyond her real years, particularly in consequence of the changes of the face which follow the total loss of teeth, applied for advice on the 4th of June, 1822. She had had occasional hæmoptysis.

The glandular substance of the left breast appears indurated and irregular, it is moveable on the muscle to which it presents a flat surface, and the skin is not yet adherent to the mass beneath. The nipple, however, seems in a slight degree retired, and the integuments around the areola are formed into small circular folds. Upon handling the tumour, she does not make any complaint of pain. She has directed my attention to an axillary gland, rather because she never perceived it until lately, than on account of any uneasiness which she now experiences. In this gland I cannot perceive any existence of disease.

The right mamma is also the seat of tumour, the bulk of which does not exceed the size of a hazel nut. It is situated at the axillary side of the nipple. It is moveable, without pain, and seems to be an enlargement of the lymphatic gland of this part of the breast. It is to be observed that both the mammae are very small, appearing as if they never had arrived at a perfect state of development.

I prescribed for this lady a course of blue pill, pil. ruf., and ext. conii, with a mercurial plaster to the mammae.

July 10th: She has continued this plan with very little interruption; the general health is manifestly improved, but I cannot say there is any amendment in the state of the mamma.

In six months afterwards, it was communicated to me that the breasts had lost their pain, and that the tumours had nearly disappeared.

#### CASE 4.

Mrs. W. of Clones, aged 45, many children, somewhat corpulent, but rather sallow, perspiring appearance, good pulse, appetite, and regular bowels; free from cough, indigestion, and every visceral disease; is affected with tumour of left breast.

It is situated in the lower part of the gland, and is to be felt most readily by placing the hand in the angle be-

tween the breast and the integuments beneath it. It is situated transversely, about four inches long by two in width; is free from all adhesion, and is without superficial discolouration. Between the superior margin of the mamma and the clavicle, a tumour exists so large that the hand barely grasps its boundaries; it extends towards the axilla as far as a line descending from lower process, and passes to the right margin of the sternum; firm, regular, fixed, unconnected with mammary tumour; red on elevated summit, with confluent enlarged veins, which are not raised above the surface. These seem as if filled with brown blood. The tumour is elastic, and not painful, unless when pressed where it is red; it involves the pectoral muscle, and Mr. Henry, an intelligent young surgeon, who saw it when no larger than a marble, leads me to conclude that it was then in its origin. It appears to be now fixed to the ribs and their cartilages which most probably it extensively involves. No distinct gland in axilla, yet there a thickening of the nerves and vessels exist. There are occasional darting pains in the tumours, and even sleepless nights, perspiration, and irregular bowels; is of a year's duration, and both tumours commenced nearly at the same time.

Venesection, leeches, and a variety of local applications were directed, with mercury. In consultation with Mr. Colles and Sir Philip Crampton, it was agreed that an operation was out of the question. Quinine and sulphuric acid were ordered, with opium at night. Saturnine lotion, rest, and to avoid all local stimulants, were the principal remedies in this hopeless case.

#### DISEASE OF THE GUMS.

Hypertrophy of the gum is an uncommon disease. Having met with a well marked case of it, I proceed to describe it, and to notice the treatment which was successfully employed. A poor woman, aged 55, presented herself for advice about six weeks ago. She was very sallow, much emaciated, and fainted occasionally.

Her teeth seemed all buried in a large mass of very florid and spongy gums, which projected irregularly, and threw forward her lips, especially the upper one. All her functions were regularly performed, and there was no evidence of any other disease, so that her wasted appearance and debility may be attributed to her impaired mastication, for she used no food but slops, and those not of a nutritive character.

She applied at several institutions for advice, and she was treated with astringent washes and with sundry caustic applications, but from these she derived no advantage whatever.

I punctured the most prominent and most vascular parts of the hypertrophied mass. The mouth filled rapidly with blood, so that I was soon obliged to desist my operative proceeding, fearing the loss of blood might lead to syncope. I renewed the operation the next day, avoiding those parts on which I acted the day preceding. The mouth rapidly filled with blood, she grew very languid, and I again desisted. On the third day I was more confident, and I punctured a highly vascular tumour. The bleeding was less than the day before, and ceased quickly. The fourth day the disease had yielded, and the hypertrophy was a little less. This plan was pursued up to the present time, allowing one, two, or three days to intervene between the operations, as circumstances seemed to require. Fifth day, the gums have resumed their natural size and aspect. No medicine was administered. I should observe that this disease was accompanied with fetor, difficult articulation, as well as difficult mastication.

I have not called this disease either epulis or scurvy. The former disease, though sometimes originating in no assignable cause, is usually preceded by an abscess near a carious tooth, or a carious affection of the maxillary bone. It rarely, if ever, engages the whole gum, is confined to a part, and grows by a pedicle, it is but little painful, and may acquire in time even a cartilaginous hardness, though the fungus is covered by a fine, shining membrane, which is pale and red, with a viscid discharge which oozes through

many small openings on its surface. But this may become puriform or even bloody. It was much more with the latter affection, and did most certainly resemble it, but only at the commencement of the disease, when all other symptoms are absent, for none of them existed here.

**SINGULAR DISEASE—VICARIOUS MENSTRUATION—PROFUSE HÆMORRHAGE FROM THE MOUTH—NERVOUS SYMPTOMS—TREATMENT—RECOVERY.**

The 6th of June I was called to visit Miss C., whom I found extremely nervous and very pale. When she lies on the left side a large quantity of bloody water issued from the mouth, unaccompanied by cough or sickness of the stomach; pulse 90, and very steady; the temperature of the body is natural; the whole of the right side of the trunk, the right arm, and thigh, are exceedingly tender when they are touched, while the least motion gives considerable pain. The under region of the trunk is accurately bounded by the mesial line; tongue clean, rather red; no appetite or thirst; bowels costive; sleeps badly; the chest and abdomen are free from organic disease; she is sometimes much depressed in spirits, often very cheerful.

I ordered minute doses of vinum colchici and full doses of infusion of roses and quinine; the first with a view to the state of the right side; the second with a view to the sanguineous discharge. I attended to the bowels, and fearing that something was wrong in the head, I advised small doses of mercury frequently repeated. This line of practice was suggested by the strange tenderness which prevailed, as well as from a vertiginous sensation she sometimes experienced for some days before she took to her bed.

My next visit was the 16th of June. The medicine was continued in the meantime, and the mouth was now slightly sore; the pulse 90; tongue clean; less bloody fluid by the mouth; she menstruated profusely during the last two days, previous to which the bloody fluid had much decreased; the bowels were costive; spirits very variable; she had some headache. Vesicatorium vertici. A grain of ioduret of iron was ordered three times a day. I now desired her removal to the country, and a discontinuance of the mercury.

In a week the hæmorrhagic fluid had ceased, and the pain and tenderness disappeared.

July 12th: Her apothecary called to inform me that my plan had been followed to that day, when she quite convalesced.

Vicarious menstruation is a very rare disease. I am not aware, however, that the menses have ever made their appearance in the force in which they are seen in this disease.

Every medical person has seen a substitute for the menstrual discharge issuing from the nose, the puncta lachrymalia, the gums, the skin, the ends of the fingers, the umbilicus, and even from strumous sores on the neck, but I am not cognizant, from my experience, of its ever having taken place in the quantity it did in this instance, or in the same situation.

**NOTICE OF A FUNGOUS HEMATODES IN THE ORBIT.**

Kelly, before death the tumour had attained to an immense size, standing out from the orbit like a small melon. A slough of a dark colour, and about the dimensions of a large walnut, appeared in the centre. In a short time this was detached, and immediately a copious hæmorrhage took place, which produced extreme exhaustion. His sufferings now were of the most intense character; night and day he was harassed with torturing pains, which he referred to the posterior part of the head. About a month before the fatal termination of the disease, two or three of the molar teeth belonging to the upper jaw became loose, and soon dropped out. To this there succeeded a continual flow of a thin sanies, so exceedingly fetid as to add considerably to the miseries of the unfortunate patient. He daily became worse; the hæmorrhages were more frequent;

the exhaustion was extreme; he lapsed into a state of deep coma; and death now concluded his temporal calamities.

*Examination of the body.*—It is remarkable that the tumour, which before death had arrived at so considerable a magnitude, immediately after that event became contracted to about one-half of its original dimensions. Its colour was completely altered from a dark red to a perfectly pale cast. Its structure now was more firm and resisting. During life a large chasm occupied its centre; now its extent became amazingly diminished, and instead of it, a mere depression remained behind. On making a vertical section of the head, we obtained a correct knowledge of the extent of the disease. The orbital process of the frontal bone was nearly completely absorbed, and the diseased structure in this situation pressed upon the brain, on the surface of which we remarked a dark brown spot, about the size of half-a-crown. The disease had extended backwards towards the superior orbital fissure, and the part of the brain corresponding to this situation presented the same appearance as before described. The antrum became engaged in the disease, and the superior maxillary bone was spread out and absorbed in several places. The root of the tongue also became implicated.

The septum nasi was completely absorbed: the tumour had passed through and occupied part of the other cavity. There was no remarkable appearance presented by the optic nerves. No section of the tumour has been made, but the eyeball was not primarily engaged. J. T. K.

**PROCEEDINGS OF SOCIETIES.**

**ROYAL MEDICAL AND CHIRURGICAL SOCIETY.**

**ON THE PATHOLOGY OF RHEUMATIC AND NON-RHEUMATIC PERICARDITIS.**

By Dr. ORMEROD.

THE author commenced by a reference to the researches of the late Dr. Taylor, who had satisfactorily shown that acute rheumatism was not exclusively the cause of pericarditis, and who had also called attention to the importance of granular disease of the kidney in reference to this morbid condition. The author desired to limit the use of the word pericarditis to present inflammation of the pericardium; and this analysis referred exclusively to cases of this nature. The means of investigation comprehended complete records of 1410 cases observed under nearly similar circumstances; that is, in the wards of different hospitals. Of these, 1249=88.59 per cent. were not cases of rheumatism; 161=11.41 per cent. were admitted on account of rheumatism, or suffered from it while under observation. Of the whole number, 85=6 per cent. had recent pericarditis, observed during life, or discovered after death, and were thus distributed:—

24=1.92 per cent.	occurred among 1249 non-rheumatic cases.
61=37.88 per cent.	161 rheumatic cases.
85=6 per cent.	1410

The mean age of 61 subjects of rheumatic pericarditis was about 21; the mean age of 24 subjects of non-rheumatic pericarditis was 42; the extremes being 7 and 63 years. As to the different causes of the pericarditis:—

Rheumatic.....	61 cases coincided with acute rheumatism.								
Non-rheumatic of local origin,	<table border="0"> <tr> <td>7</td> <td>ensued on inflammation of lungs or pleura.</td> </tr> <tr> <td>2</td> <td>ensued on malignant disease of the pericardium.</td> </tr> <tr> <td>1</td> <td>ensued on old cardiac disease.</td> </tr> </table>	7	ensued on inflammation of lungs or pleura.	2	ensued on malignant disease of the pericardium.	1	ensued on old cardiac disease.		
7	ensued on inflammation of lungs or pleura.								
2	ensued on malignant disease of the pericardium.								
1	ensued on old cardiac disease.								
Non-rheumatic of constitutional origin	<table border="0"> <tr> <td>6</td> <td>coincided with granular disease of kidney.</td> </tr> <tr> <td>4</td> <td>coincided with hæmorrhage or exhaustion.</td> </tr> <tr> <td>2</td> <td>coincided with scarlatina or erysipelas respectively.</td> </tr> <tr> <td>2</td> <td>were inexplicable.</td> </tr> </table>	6	coincided with granular disease of kidney.	4	coincided with hæmorrhage or exhaustion.	2	coincided with scarlatina or erysipelas respectively.	2	were inexplicable.
6	coincided with granular disease of kidney.								
4	coincided with hæmorrhage or exhaustion.								
2	coincided with scarlatina or erysipelas respectively.								
2	were inexplicable.								

The date of the accession of pericarditis was determined in 33 of the rheumatic cases. The mean of these observations gave the 10.5th day of the rheumatic attack as that on which the pericardial complication most commonly super-

vened. The question, whether a first or second attack of rheumatism was more likely to be accompanied by pericarditis, was beyond the reach of hospital statistics. This source of information was silent also on the question, whether pericarditis be more likely to occur in severe or in the slighter cases of rheumatic fever. It might, however, be safely inferred, that the severity of the articular and pericardial affections bore no very close relationship to each other. It was certain that the most severe, even fatal pericarditis, might occur where there was but faint evidence of articular affection, and this latter condition might exist in the most aggravated and intense form without involving the addition of pericarditis to the other sources of distress. The author then entered upon the consideration of the subject of non-rheumatic pericarditis of local origin; and a question of importance here presented itself—What was the influence of preëxistent cardiac or pulmonary affections in inducing inflammation of the pericardium? The question was of equal importance in relation to acute rheumatism. The relation of pulmonary inflammation to pericarditis was thus illustrated:—In the 1410 cases, the basis of this inquiry, some form of pulmonary inflammation—that is, pneumonia, pleuritis, or pleuro-pneumonia—was ascertained to exist, either by auscultation or dissection, in 265 cases. Of these—

117 had pneumonia,	of which 19 had recent pericarditis.
86 had pleurisy,	6                      "
62 had pleuro-pneumonia	8                      "
265	33 = 12.4 per cent.

In the rheumatic class, pericardial inflammation commonly preceded, yet sometimes, though rarely, followed, pulmonary inflammation. The non-rheumatic class told quite a different story; here pulmonary inflammation had apparently a distinct influence in inducing pericarditis, and this influence was most evident in cases of pleurisy; and clinical observation bore out the conclusion, that the pericarditis was subsequent to, and probably contingent on, the pulmonary inflammation. The author then referred to the comparative fatality of non-rheumatic compared with rheumatic pericarditis, and also to the desirableness of instituting an exact comparison between Bright's disease of the kidney and acute rheumatism, in respect to their tendencies to induce inflammation of the pericardium. In conclusion, the author desired to ascertain how far the results obtained by his present analysis agreed with those of the published cases of Dr. Taylor, who had made the subject of non-rheumatic pericarditis so peculiarly his own. The deductions seemed identical, and one rose from the perusal of those elaborate clinical reports with a conviction that non-rheumatic pericarditis was more within the province of the anatomist than of the physician. It was a disease with few or no symptoms, its physical signs recognized more often by a chance discovery than on the suggestions of the disease, and its morbid changes small in amount and apparently inactive; and where opportunity had occurred of watching the disease some time previous to death, it had been apparently without effect on the general symptoms, its presence or absence being determined by the ear alone; and still, in these, its connexion with the fatal termination had appeared to be that of a coincidence rather than of a cause.

Dr. Mayo thought the statement of the author, that non-rheumatic pericarditis was not a fatal complaint, or directly productive of death, was open to much doubt. Non-rheumatic seemed to be not a rare affection, and though its symptoms might be slight, and its presence be in some instances undiscovered, yet he was not, therefore, prepared to admit that it was less dangerous to life. Examples of the gravest pathological conditions attended with extremely slight symptoms, were constantly occurring. He recollected a striking instance. A man was admitted into the Marylebone Infirmary, having been struck with apoplexy. The symptoms were apparently trivial, but in a few hours he died. At the post mortem examination, evidences of severe and extensive pneumonia were presented by both lungs, and in one a considerable extent of gray

hepatization prevailed. A case had been referred to in the paper, in which pericarditis supervened on an attack of mania. Now, in this instance, it would be interesting to consider in what relation the derangement of the nervous system stood to the existing inflammation, for it was not improbable that the impairment of function which the nervous system suffered, disordered the processes of nutrition in the heart, and thus became the predisposing agent to inflammation of that organ.

Dr. FULLER agreed in the main with the author of the paper, which was a valuable addition to our knowledge on the subjects which it discussed. There were some points in it, however, from which his (Dr. Fuller's) limited experience led him to differ. And first with respect to the frequency of the occurrence of pericarditis after first and secondary attacks of articular rheumatism. The author of the paper considered it to be more frequent after secondary attacks; his (Dr. Fuller's) experience was decidedly different. He could not just then recollect the precise numbers, but certainly cases of pericarditis under his notice had been more frequent after the first attacks of articular rheumatism. Dr. Ormerod had stated that the severity of the attack of acute articular rheumatism was no criterion of the liability of the pericardium to become affected; and that, in many severe cases, pericarditis did not occur at all; whilst in other cases in which the joints were scarcely affected, pericarditis did occur. This went to prove that pericarditis was only one symptom of the paroxysm of acute rheumatism. With respect to the occurrence of inflammation of the lungs in fatal cases of rheumatism, and their importance, he agreed rather with Dr. Ormerod than Dr. Mayo; for out of twenty-seven cases which he had recorded, in twenty-five there was pericarditis; and pneumonia, pleuritis, or very acute bronchitis in twenty-one. It would be difficult to say, in these cases, which of the inflammations immediately produced the fatal result, and how far the disease of the lungs would have had a tendency to death, had pericarditis not been present.

Dr. HEALE mentioned a case of sudden death in a man apparently healthy, with the exception of a slight cold, in whom it was found, upon examination, that one lung was completely hepatized, and the other greatly congested. He also had a strangulated hernia in a state of gangrene. Yet there were no symptoms (laughter).

Dr. COPLAND felt obliged to the author for the very practical and literary way in which he had brought his paper before the fellows of the Society. The association of disease, as exemplified in Dr. Ormerod's communication, showed us that, in practice, we must not look at cases of disease as always simple, but frequently as complicated as those under discussion. All these were connected with the morbid condition of the blood, and to this we must look as the cause of the articular rheumatism, the pericarditis, pleuritis, &c. All these were evidences of the blood being in an abnormal condition, from whatever cause it originated. Several organs became affected, and when an important disease existed, it masked the minor one. We saw the same train of phenomena in Bright's disease, in which inflammation of the serous membranes was liable to occur from the non-elimination of morbid matter from the blood, and its consequent circulation through the system. These combinations of diseases should be viewed in our routine of practice as the result of the morbid action in the system.

#### ON THE CURE OF NÆVUS AND ERECTILE TUMOURS BY ELASTIC SUBCUTANEOUS STRANGULATION AND SECTION.

By Mr. STARTIN.

The author, in his paper, describes a new method of treating this malady, which consists in environing the nævus or tumour with a ligature passed beneath the skin, by means of a long angular-pointed needle, so as to include the morbid parts in a triangular space, extending a line or so beyond the boundaries of the nævus. To one angle of this subcutaneous thread, elastic tension is applied by means of a vulcanized india-rubber ring or band, which occasions it to ulcerate or cut its way through the vascular structure constituting the malady, and thus obliterate its

vessels and cure the complaint. The author describes two methods of operating by elastic strangulation. The first is to fix the tension upon the subcutaneous thread half an inch from its exit at the most convenient angle for applying it, without previously tying a knot upon the tumour, as in the case of the ordinary subcutaneous ligature. The second method is to employ a subcutaneous ligature, and tie a knot upon it so as to strangle or arrest the circulation in the tumour before applying the tension. In most cases of extensive nœvus, both methods are required; the first, where the complaint is superficial, or implicates some of the features, as the eyelids or nose, for example; the second, where the malady is deeper, and may be regarded rather in the light of an erectile tumour containing large blood-vessels, the too sudden division of which might be productive of troublesome hæmorrhage. The author illustrated his paper by a wax model cast from a nœvus, which had been under treatment; and he brought forward a case of instruments which contained one or two original contrivances to facilitate the operation he described. The cases where "elastic strangulation and section" were deemed most applicable were examples of the malady involving various parts of the face or hairy scalp, where the cure by extirpation with the knife, by caustics, by breaking up the nœvus in various manners, or by ordinary subcutaneous ligature, would either produce too great disfigurement, risk of hæmorrhage, loss of skin, or distortion of the features, to be advantageously resorted to. Several cases were cited in illustration of the plan advocated, and the success attending it, in one of which as many as thirty operations had been previously tried, by various surgeons, without a satisfactory result. For the details of these cases, as also for a more complete account of the operation, reference must be made to the paper itself. The author incidentally remarked, that this operation, as far as the employment of elastic tension is concerned, appeared to him to be capable of adaptation to several other departments of surgery where such a force might be required, or where a ligature is used. As examples, he instanced the retained ligatures of arteries in healing wounds, or after tying uterine polypi, deep portions of tumours, hæmorrhoids, varicose veins, as also in the extraction of the guinea-worm, the maintaining in position some fractures and dislocations; but, as these considerations were foreign to the subject under notice, he concluded by stating, that since the writing of his paper, six months ago, he had successfully employed elastic strangulation and section in four cases of nœvus; and that he was authorized by Mr. Paget, of St. Bartholomew's, to mention, that he had twice adopted the plan with a fortunate result.

#### MEDICAL SOCIETY OF LONDON.

DR. MURPHY exhibited an instrument formed like a male silver catheter, with an enlarged, open, and somewhat flattened extremity. It had been used by Mr. Robertson of Manchester, in a case of turning, in which, from the delay in the passage of the head, the life of the child was endangered. It was passed up to the mouth of the child on the fore and middle fingers, and air communicated to the lungs. It was recommended to be used in cases where the head was so placed in version, and in foot or breech presentation.

Mr. DENBY had employed a flat female catheter for the same purpose many years ago.

Dr. RADCLIFFE read a paper

#### ON THE PATHOLOGY OF AFFECTIONS ALLIED TO EPILEPSY.

He began his paper by stating that his inquiries in muscular physiology and pathology lead to the conclusion that muscular contraction is not a sign of increased stimulation, but the reverse—a sign of unresisted molecular attraction on the withdrawal of nervous, vascular, or other vital or physical force—a sign of a dynamic change in every respect analogous to that which takes place in a bar of metal when heat is withdrawn, except that in the case of the muscle the repellent force to be withdrawn is more complex in its nature. On a former occasion he had endeavoured to show that the phenomena of epilepsy were only

explicable on this view. On the present occasion he proposed to extend the demonstration to affections allied to epilepsy; or, in other words, to all forms and conditions of muscular disturbance other than epilepsy.

1. The first step in the inquiry was to show that the temperament or predisposition in these affections was invariably marked by a decided want of nervous, vascular, muscular, and other strength.

2. The next step was to show, by a successive examination of the vascular, nervous, and muscular systems, and by some facts in the general history of the maladies, that this want was most conspicuous during the convulsive or spasmodic manifestations.

(a) The circulation was often undeniably below par, as in tremulousness, palsy, cramp, chorea agitation, the convulsions of hæmorrhage, in catalepsy, and cadaveric rigidity. So again in fever, in which case also the history seemed to be that the convulsions happened because the circulation was depressed. Thus, the initial rigors, cramps, or convulsions of ordinary fever, cholera, or severe small-pox, pass off as the system rallies into the stage of true fever, and recur again in the period of final prostration, and go on *pari passu* with that prostration—subultoid movements and sinking convulsive struggling and dissolution, and cataleptoid rigidity and death. Nor is it really different in hysteric convulsion, hydrophobia, and tetanus. In hysteria, convulsion is the companion of syncope; and just in proportion as the symptoms partake of excitement the convulsive characters are lost. In hydrophobia, the particulars of four cases were related; in three of these the pulse was imperceptible, or very faint and feeble, during the height of the fits; in the fourth, the pulse was somewhat better, and in this case the symptoms had little of a convulsive character, being more like those of ordinary hysteria. In tetanus, the absence of fever (a fully recognized fact) was insisted upon, and two cases, and some other evidence, were given to show that the symptoms stood related to the very opposite of fever. The question of plethora was also gone into, and some arguments adduced to show that when any signs of plethora existed, these were passive rather than active in their character, and most unequivocally passive during the continuance of the convulsion.

(b) It was then argued that this debilitated or prostrated state of the circulation involved a corresponding inactivity in the great nervous centres; after which the author passed to direct evidence. In many cases vacillation, fatuity, senility, sleep, stupor, insensibility, unconsciousness, exhaustion, death, could be pointed out as coincident with the convulsive manifestations: in none were there any signs of nervous hyper-activity. The mind had been perfectly inactive in two cases of catalepsy which the author had seen, and a doubt was expressed whether, in those exceptional cases of trance which were classed with catalepsy, there was the same degree, or any degree, of muscular rigidity. A dream was no evidence of hyper-activity. The character of the delirium in delirium tremens, the other symptoms, and the kind of treatment requisite, all showed that the brain was not over-active in this form of convulsive action; and just in proportion as the symptoms became sthenic in their character, they changed from delirium tremens to delirium *à potu*, and lost their convulsive character. Again, the convulsions of cerebral congestion or inflammation never occur in the active or inflammatory stage, but always either in the incipient collapse of the accompanying fever, or in the secondary collapse and after effusion; when dilated pupils and insensibility speak sufficiently as to the real state of the brain. Dr. Radcliffe also contended that there was no proof that spicula of bone pressing upon the brain produced convulsion by exciting irritation, and much proof that they acted by pressure, or by the alteration of structure, exhaustion, or effusion, to which they gave rise, all of which would interfere, more or less, with the vigorous discharge of the cerebral functions. With respect to the medulla oblongata, the only sign which would seem to indicate over-activity in this organ, is the congestion which

has been frequently found in cases of hydrophobia, and this was much more likely, considering the collateral evidence, to be related to the inflamed gullet and glottis, than to the spasm of that disease. The want of muscular tone and strength, presently to be mentioned, was also cited as an argument against any hyper-activity in the spinal cord. The absence of all post-mortem signs indicative of over-activity, and the presence of signs of an opposite character, such as atrophy, softening, serous effusions, and so on, was also insisted upon. The possible alternation, of mental and nervous activity with the state described was fully admitted, but not the coexistence.

(c) The muscles were, often undeniably weakened. In tremulous, hysterical, choreic, cataleptic persons, they were wanting in real strength, in firmness, and in reparative energy. In the subjects of palsy they were always atrophied and often degenerated. Muscular strength was completely prostrate in fever. An interesting class of cases was also referred to, which has lately been attracting considerable attention on the Continent, under the title of *trophoneurosis*, and some cases given in illustration, in which the phenomena of clonic and tonic contraction were coincident with distinct and unmistakable atrophy of the affected muscles. Having mentioned these facts, the author then proceeded to show how the convulsions of hydrophobia, and the spasms of tetanus, did not in themselves imply over-activity of the muscles concerned, seeing that violent convulsions were associated with mortal hæmorrhage and some other forms of death, and tetanoid rigidity with final extinction of all life. As explaining the real nature of the latter phenomenon, it was an important fact, now pretty generally admitted, that the more completely the vital powers had been exhausted before death, as by extreme old age, or phthisis, the sooner did cadaveric rigidity occur.

(d) A rapid review was then taken, one object of which was to show that fright, grief, exhaustion, prostration, cold, and not the opposites, were those to which the names of *exciting causes* were applied.

(e) The last step in the inquiry was to disprove the necessary connexion between the convulsive phenomena under consideration and local disorder, and particularly to disprove the connexion between them and nervous disorder. It was intended that the contemporaneous and kindred disturbance which was clearly discernible in the nervous, vascular, and muscular systems, was against such a view. The primary evil determining and enhancing the general debility, depression, or prostration, of which the convulsion was a symptom, might be in any of these, or even in other systems, or in all equally, but not in one preëminently—not even in the spinal cord.

Dr. F. WINSLOW said there was no lack of subjects for discussion, seeing that the views contained in the paper which had been just read, were in direct opposition to those which the members of the Society had been accustomed to listen to. He thought there were some cases of catalepsy which did not bear out what had been stated of that affection—cases in which the mind was preternaturally active. He thought, also, that it might admit of a doubt, whether the depression, of which so much had been said, was not often secondary.

Mr. PILCHER must beg to dissent from many of the positions taken by the author of the paper. He questioned the statement that cadaveric stiffness comes on sooner in very old persons, or in those who have died after long-continued exhaustion, than in those who have been cut down suddenly in the full vigour of life. He questioned, also, the existence of prostration in tetanus; on the contrary, he had seen many cases in which there was every sign of vigour, and mentioned a recent case in point. The convulsions of children, he said, were most likely to happen in the strongest children. He did not admit that extreme prostration was involved in the convulsions of hæmorrhage; nor did he consider, as the author seemed disposed to do, that lacerations in tetanized muscles were proofs of weakness. He looked upon the fact of a muscle continuing to contract, as a proof of the active nature of the phenomena, and he

agreed with the views generally entertained on the subject.

Dr. T. THOMPSON had not heard all the paper, but what he had heard seemed to him to be at variance with what is known of the phenomena of epilepsy. (Here Dr. Radcliffe rose to say, that epilepsy had been purposely excluded from the paper of the evening, but that it had been discussed on a former occasion, and similar views maintained in relation to it on an extended series of arguments.) Dr. Thompson then said that convulsions occurred frequently in persons distinguished by mental power, and were in some instances, of which he mentioned one, benefited by bleeding. Some years ago, there was a quack who gained very considerable reputation for the cure of several kinds of convulsive diseases, a part of whose treatment was the enjoining of long walks—a practice more likely to do harm than good; if there was always that fundamental debility and prostration of which they had heard.

Dr. HARE considered the paper as one of great importance, and he agreed in the main with the deductions contained in it. He thought, however, that the importance of local disease had been underrated and instanced the confining of the symptoms to one side as a proof in point. Nor was he satisfied that convulsions never occurred in plethora or in fever. He agreed with what had been said about catalepsy and cramp, and thought the cases referred to by the Vice-President were cases of ecstasy, rather than catalepsy. He ended by hinting at a little fact in relation to cramp, which it might be useful to know—that this troublesome companion might be kept at a distance by tilting the bed, so that the feet and legs should be in a slightly depending position. The *modus operandi* was the keeping more blood in the legs, and this would harmonize with Dr. Radcliffe's views.

Dr. CHOWNE agreed with the remarks which had been made on the value of the paper, but questioned if the attempt which the author had made to generalize the various diseases alluded to, and find an analogy in them to epilepsy, was either useful or correct. Indeed most of them bore no analogy to epilepsy, the peculiarity of which was not the convulsion, but the threatening asphyxia. In this particular, hysteria, chorea, the tremulousness of palsy, and delirium tremens, differed from epilepsy in character, cause, and treatment. Puerperal convulsions, the convulsions of children from disordered bowels, and those which preceded small-pox, bore more resemblance to epilepsy. He differed with Dr. Hare in regard to the effects of chorea. He had seen cases of it, in which the fatigue from the uncontrollable motions was most severe and painful. In catalepsy, the mind was not always in abeyance. He had seen a case in which consciousness was complete during the entire attack; and with the exception of the catalepsy, the patient was in good health.

Dr. SIBSON agreed in a great portion of what Dr. Radcliffe had advanced; but whilst he admitted that in many cases convulsions had their origin in anæmia, in others they arose from an opposite condition. In the paper, the author had classified some diseases which were allied to epilepsy with some that were not. Convulsions, in some diseases, arose from a lowering of the nervous energy; in others, as hydrophobia and tetanus, there might be, and usually was, great excitation of the nervous system, with great muscular power. He had seen three cases of hydrophobia: two of these occurred in very powerful men; in the third case the man was not strong. We found in practice, that the distinction which he (Dr. Sibson) had mentioned was borne out. Thus in convulsions arising from a depressed state of the system, as in chorea and hysteria, we found quinine, iron, and medicines which raised the tone, of most service; but in tetanus and hydrophobia, we subdued the nervous system by belladonna, chloroform, and other sedatives.

Dr. RADCLIFFE said that he was under a great disadvantage in having to bring such a subject forward in a partial form, and in so short a time; and all that under the circumstances he could hope to have accomplished was to have done something to shake conviction in existing views;

and to excite inquiry. He would not attempt to reply to the individual speakers, but would content himself with one or two general remarks. He was fully sensible of the imperfect manner in which the subject had been treated; but he thought himself fairly entitled to the benefit of the doubt in any one individual case, when the general evidence derived from the whole class of cases was in his favour. This remark had especial reference to the objections which had been made to what he had said about the uncongeniality of convulsion and plethora or fever. He would, however, distinctly say that he himself had never met with these individual objections; he had never once felt a pulse in which, during the convulsion, the evidence afforded was not distinctly opposed to either plethora or fever. He had often, indeed, found the pulse to rally very speedily, but never until the convulsion was over. With regard to the remark of the Vice-President respecting catalepsy, he would merely say that a question had been suggested in the paper as to whether the muscles were as rigid in cases of ecstasy as in ordinary catalepsy, which question had not been answered.—*Lancet*.

### HOSPITAL REPORTS.

#### KING'S COLLEGE.

#### *Large Calculus in the Female, of which the Nucleus was a piece of Cork.*

(Under the care of Mr. PARTRIDGE and Mr. HENRY LEE.)

JANE P., aged 42, married, was admitted October 20, 1851, under the care of Mr. Partridge, suffering from stone in the bladder. Until four years ago she seems to have enjoyed excellent health; about that time she was admitted into University College Hospital, probably for an attack of pleurisy. Two years before her present admission, she was in this hospital, under the care of Dr. Todd, for paraplegia, but was able to walk after six weeks, at which time she was discharged. At that period she felt a slight inconvenience in passing her water, but not to a sufficient extent to excite attention. She has, however, grown worse up to the present time.

The symptoms on admission were, very severe pain in passing urine, the stream frequently stopping suddenly; the fluid very thick, mixed with blood, and depositing a ropy, unhealthy-looking mucus on standing; the general health much broken down, great pain across the back, very little liking for food, frequent sickness, and constant nausea after meals. Mr. Partridge, on examination, detected a calculus, which was supposed to be of the phosphatic kind. The patient had been a fortnight under the care of Dr. Budd, who had had her transferred to the surgical ward, when the nature of the disease was ascertained. Two days after she had been placed under Mr. Partridge's care she was attacked with a severe paroxysm of pain. Towards night, Mr. Lawson, the house-surgeon, tried to introduce a catheter and draw off the urine, but could not get the instrument into the bladder, as the stone was firmly impacted in the neck. Mr. Lee, in the absence of Mr. Partridge, was now called to the case, and found the urethra so wide that the patient had herself tried to remove the stone with the aid of the index-finger. Mr. Lee was able to introduce the lithotomy forceps into the bladder, but the stone was so large that it could not be withdrawn without an incision upwards, and a very slight one downwards. No unfavourable symptom occurred, hardly any incontinence was noticed, and a week after the operation the patient passed her urine normally, and without pain. The stone weighed two ounces, and was of an oval, flattened shape. On a section, it was found to have formed around a nucleus which looked very much like wood, but on a closer examination the foreign body was found to be a piece of cork. The section was about two inches in diameter, and the concentric layers of phosphate of lime were extremely regular and numerous.

It is hardly worth while inquiring how the piece of cork reached the urethra. Numerous cases have been put upon record of patients, both male and female, young and old,

who, either from a depraved taste, or to remove obstruction, have passed various objects down the urethra. A case in point, treated at Guy's Hospital, will be found below.

As to Mr. Lee's case, we would just note how important it is for the subsequent well-being of the patient to make the urethral incision, when such is found necessary, directly upwards, ■ cuts downwards or towards the side heal with much difficulty, and are very apt to give rise to incontinence. We witnessed, a short time ago, an operation of the same kind, performed by Mr. Simon, at St. Thomas's Hospital. The case offers several points of interest, as will be seen by the following details:—

#### ST. THOMAS'S.

#### *Calculus in the Female; Extraction by Dilatation.*

(Under the care of Mr. SIMON.)

The patient is aged about 35, and was operated upon by Mr. Simon on October 19, 1852. The poor woman had been suffering severely from the usual symptoms of stone for several years, and no course was left but to make an attempt at removing it. The calculus was not supposed to be of large size, and the patient being conveniently placed on a table, Mr. Simon, after ascertaining the position of the stone with the sound, attempted its removal by the aid of small forceps. This was, however, found extremely difficult, owing principally, as was afterwards found, to the elongated form of the stone. The dilator was now used, and so completely did the urethra give way under its use, that, after careful stretching, the canal first admitted the little, and finally the index-finger. It had now become plain, from small fragments which came away with the instrument, that the calculus was of the phosphatic kind, and its position could be ascertained by the finger passed into the rectum. Larger forceps were now used; but the withdrawal of the calculus being still difficult, Mr. Simon passed one index-finger into the rectum, the other into the bladder, and by hooking the latter finger succeeded in extracting a stone of an elongated form, about the size of a common gherkin. The operation had been somewhat protracted, the hæmorrhage rather abundant, and the patient not having taken any chloroform, had experienced great suffering. But these circumstances had no prejudicial influence on her recovery; she progressed very favourably, and at the present time she is perfectly well, having left the hospital but a few days after the operation, no sign of pain or incontinence being noticed.

#### GUY'S.

#### *Stone in the Male Bladder; Extraction; Recovery.*

(Under the care of Mr. COCK.)

The patient, a man aged about 47, was in the habit of passing a parsley-stem down his urethra; this practice having arisen by the man's desire of thrusting back into the bladder fragments of stone which became impacted in the urethra, or else facilitating their exit by introducing the stem moistened with saliva. Whether, besides the mechanical effect, the patient expected any benefit from the supposed virtues of the parsley plant, we cannot say; but it is at least probable that he shared in the popular prejudice on the subject. It should be noticed that Mr. Cock cut this man for stone in October, 1851; the operation was very successful, and the recovery rapid. It would appear that the phosphate of lime formed the greater portion of the calculus. After the usual incisions, on October 2, 1852, Mr. Cock felt the stone give way under the forceps, and by the appearance of the detritus, it was evident that the calculus was of the phosphatic description. Finally, however, a somewhat large mass of crumbling stone was extracted, and to it was found attached a stem of some plant about four inches long. The bladder was now carefully washed out, the remaining detritus removed, and the patient transferred to bed.

On examining the stone and debris found in the bladder, it was perceived that the ligneous stem which had been extracted belonged to the parsley plant, and that incrustations had principally formed on either extremity. There

was every reason to believe that a stone already lay in the bladder when the stem slipped into it, for the calculus removed at the operation was quite independent of the organic foreign body which was extracted at the same time. The middle portion of the latter was free from concretions; and it may be supposed that the extremities, being in permanent contact with the mucous membrane of the bladder, received for a long period the deposits formed by the alkaline urine coming down from the kidneys.

The patient has since done well; he was not aware of a portion of the stem having broken off, and will probably, for the future, avoid passing for himself instruments of so primitive a kind.

It is rather curious that fragments of catheters, of bougies, stems of all kinds, &c., should, with such great facility, slip down the urethra; and towards the bladder, since the direction of the follicles, mucous glands, and muscular fibres is of such a kind as to favour expulsion and resist introduction. Every surgeon is aware that a slight amount of force is always required for passing an instrument down the urethra, and that some trifling opposition is generally encountered. It would, therefore, appear likely, when foreign bodies slip into the bladder, that the latter exercises a kind of suction, which favours their passage into the cavity. We need not remind our readers of the numerous cases of this kind which have been recorded. We shall just mention the pen-holder removed from the urethra of a patient by Mr. Birkett at Guy's Hospital; the hair-pin removed by Mr. Bransby Cooper at the same institution, and the bristly stem of fir which a Frenchman was in the habit of passing down his urethra. Examples of globular bodies slipping into the bladder are perhaps more rare; but concretions will, as is well known, form exactly around the nuclei. A very striking instance of such formation was some time ago brought, by Mr. Haynes Walton, before the Medical Society of London. In that case, horse-beans had been maliciously passed down a poor man's urethra, and phosphatic incrustations had formed around them in so exact a manner, that the whole presented the appearance of a globular calculus, within which, however, the bean lay quite loose, which latter circumstance might be made manifest, either by shaking one of the stones, or making a section.

Being on the subject of foreign bodies introduced into the urethra, we would just allude to a case which was some time ago under the care of Mr. Stanley at St. Bartholomew's Hospital, and which exemplifies not only the depraved taste to which we above alluded, but also affords another proof that urethritis, and some of its consequences, may be excited by mechanical irritation of the urethra.

#### *Diffuse Aneurism of Femoral Artery treated by Ligature.*

(Under the care of Mr. BRANSBY COOPER.)

Robert W., aged 47, a baker, carrying on his business at Dalston, came into Guy's Hospital, September 6, 1852. He was admitted under the care of Mr. Cooper, with aneurism of the femoral artery on the right side. About nine months before he came into the hospital, the patient was accidentally struck in the ham (exactly in the spot in which the aneurism afterwards made its appearance) in the following manner:—One day, as he was running along quickly with his barrow, he drove it against a post, which caused the handle to swing violently round, so that the point caught him with considerable force in the right leg, just where, according to his account of the accident, the artery passes through the tendon of the adductor magnus. The part struck was a good deal lacerated, and he suffered at the time considerable pain. Both the latter and the appearance of injury passed away, however, in the course of a few days, and nothing further was felt until six months after the occurrence of the accident, when, quite casually, one night, as he was lying in bed, he discovered a throbbing and beating tumour (as he called it) just where he had been formerly struck by the handle of the barrow. The patient had never observed this swelling before, but from this time it continued to increase in size; it also gradually became more and more tender and inconvenient,

without, however, as yet interfering much with the function of the limb. At the same time, however, the right leg became sooner fatigued than the other, and felt altogether weaker. This state of things went on without much alteration for about three months longer, until nine months had passed from the time of the accident, the patient never having sought medical advice, when one day the tumour suddenly became very painful, so much so that he was quite unable to walk, and obliged to keep his bed. The patient now sent for Mr. Toulmin of Hackney, who, after having examined the tumour, recommended that further advice should be sought, and called in Mr. Cooper. The consultation took place on the 6th of September, and in the afternoon of the same day the patient was removed to Guy's Hospital by Mr. Cooper's desire.

When admitted, it was found that the patient was suffering from a large pulsating tumour, occupying the inferior third of the right thigh on the inner side. The swelling was so extensive as to lead to the belief that it was caused by diffused aneurism, and that the blood was not contained in a closed sac. The tumour was extremely sensitive to the touch, and excited constant pain in the course of the saphenous nerve, which was in a continued state of tension by passing over the sac. The pain was so intense as to destroy rest completely, and keep up continued constitutional irritation. It was determined by Mr. Cooper that a ligature should be placed upon the femoral artery on the next day.

On the 7th of September the operation of tying the femoral artery was accordingly performed, and the patient bore it exceedingly well. Nothing remarkable occurred in the operation, excepting that, owing to the size of the limb, arising partly from fat and partly from oedema, it was difficult to ascertain the direction of the edge of the sartorius muscle, which was, however, laid bare by the first incision through the fascia lata. Upon opening the sheath of the femoral vessels, the artery, which was very large, was brought into view. Mr. Cooper next passed an unarmed aneurism needle beneath the artery, which measure was followed by slight venous bleeding. When the needle was seen on the opposite side of the artery, it was threaded with the ligature, then withdrawn, and the thread tied around the vessel. The venous hæmorrhage then immediately ceased, the edges of the wound were brought together, and the patient put to bed.

As soon as the ligature was applied, the sensitiveness of the tumour was relieved, and did not afterwards return. On the evening of the day of the operation, two grains of mercury-with-chalk, with six grains of Dover's powder, were given, and the patient passed a very good night. On the next day, when the wound was dressed, the surface of the lint was a good deal stained with arterial blood, and the wound itself had put on an appearance which led Mr. Cooper to remark that he feared secondary hæmorrhage. Cold-water dressing was ordered to be applied; the patient was given beef-tea and half a pint of porter, and as he seemed rather asthenic, he had also a little wine. On the second day after the operation, suppuration from the wound had commenced, and every tendency to bleeding seemed to have quite disappeared. Sulphate of quinine and dilute sulphuric acid were now given, and the quantity of porter increased to a pint.

From this time the patient continued gradually to improve; the discharge, however, remained more than usually profuse, the countenance frequently suffused, and it was impossible to avoid a suspicion of a tendency to hæmorrhage, sufficient to create alarm, as the time for the separation of the ligature drew near. Poultices were kept applied to the part, and strips of soap plaster put around the thigh above and below the wound, to prevent the burrowing of the matter. Healthy granulations now began to spring up, the discharge diminished, the general health improved, and on the 28th of September (that is, the twenty-first day after the operation) the ligature came away. There was no hæmorrhage, nor any other bad symptom, and the patient was discharged five weeks after admission.

The appearance of this man at the time of his coming into the hospital was not by any means such as would promise a speedy and easy recovery from a serious operation. He is a dark, sallow man, of sanguineo-bilious temperament, and at that time had a very decidedly cachectic aspect. Mr. Cooper took occasion to remark, that upon first seeing this patient with Mr. Toulmin, he received, from his appearance, a most unfavourable impression with regard to the progress of the case. Mr. Cooper, therefore, recommended to the patient to go into the hospital, instead of having the operation performed at his own house, as, among other reasons, the atmosphere of the baking-house would perhaps be injurious. With some little difficulty, the patient and his wife were persuaded to consent to the removal.

The history of this case shows it to be one of uncommon occurrence. Mr. Cooper considered that it should be placed in the class of diffused aneurism, with this unusual circumstance connected with it, that the vessel appears not to have given way until six months after the injury was inflicted. The phenomena may therefore be explained thus: either there had been aneurism before the accident, or else diseased action had been set up by the blow, and the artery had subsequently given way, owing to a morbid condition of the vessel having been established. Mr. Cooper was inclined to think that there was sufficient evidence of the latter supposition being the correct one, inasmuch as had there been aneurism at the seat of the injury when the accident happened (although the disease might have escaped the patient's observation), a severe blow from such an object as a barrow-handle would certainly have instantly burst the sac, and a diffused aneurism would have been the immediate result; whilst, in this case the swelling was not detected until six months after the accident. Those who advocate compression as a cure for aneurism, may inquire why Mr. Cooper did not adopt this milder mode of proceeding, in preference to tying the artery. In this case, however, compression was put entirely out of the question by the highly sensitive nature of the swelling, which was so great as to render the patient intolerant of the least pressure during the ordinary examination. Mr. Cooper, moreover, feared at the time that there was a more or less general diseased state of the arteries, and preferred applying the ligature in the usual manner, believing that an operation of that kind produces much less general constitutional disturbance than the long-continued compression of an artery.

ST. BARTHOLOMEW'S.

*Inflammation from Catgut introduced into the Urethra.*  
(Under the care of Mr. STANLEY.)

Edwin T., aged 16, a pale, thin, and fair boy, a clock-maker's apprentice, who formerly used to be florid and in good health, was admitted, February 2, 1851, into Darker ward. Nine days before admission he amused himself in passing a piece of new catgut, about twelve inches long, into his urethra, and he effectually did he do so, as to leave only about an inch of the catgut outside the meatus. The foreign body remained, according to the boy's account, but a few seconds in the urethra; it gave him no pain while he slid it briskly up and down; there was no immediate discharge when he removed it, and he states, moreover, that the catgut was never introduced afterwards. The patient was not in the habit of committing self-abuse.

On the fifth day after acting so imprudently, the boy saw, after passing urine, a little blood come from the meatus, though none had appeared at the time of introducing the catgut, nor afterwards. The day when this sanguineous discharge took place, the patient had headache, shivering, and general uneasiness. This trickling of blood after micturition, general feverishness, and restlessness, continued four days; the boy was then obliged to leave his master, and when laying by at home, the right testicle began to swell, and became painful. He had some medicine, but did not mention the above-stated circumstances to the surgeon who attended him. At last he told the fact to his master, who brought him to the hospital. On ad-

mission, the right side of the scrotum was found red, and the epididymis swollen and painful; there was no discharge from the urethra, though the urine presented a yellowish-white cloud; the fever ran high; there were quick pulse, thirst, &c. Mr. Stanley ordered twenty-four leeches to be applied to the scrotum; a saline mixture, and an anodyne at night.

On the next day, the febrile symptoms and pain not having abated, sixteen more leeches were placed upon the scrotum, a poultice afterwards, and antimony was added to the mixture. The inflammation of the epididymis could not, however, be controlled, and suppuration took place, the patient becoming at the same time very low and weak. The abscess on the right side broke spontaneously ten days after admission, a great quantity of pus was discharged, and Mr. Stanley opened on the same day another abscess on the left side; this gave exit to much purulent matter, after which proceeding the patient felt considerably relieved. Beef-tea and brandy had been administered as soon as debility had come on, as well as small doses of mercury-with-chalk. The patient now improved rapidly, the abscesses went on discharging less and less, the boy gained strength, and was discharged about one month after admission, in a very favourable condition.

This case might be looked upon as one of *gonorrhœa sicca*, as it has erroneously been called; but the simple fact is, that inflammation of the mucous membrane of the urethra had been mechanically excited. This urethritis did not reach the suppurative stage, but the irritation travelled along the ducts towards the epididymis, and attained there a very considerable degree of intensity. The purulent discharge from the urethra seems to depend not so much on the degree of irritation as on the kind. Mucopurulent matter secreted by the genital organs seems to have the privilege of exciting a discharge of the same kind from the mucous membrane upon which it is deposited. Irritating injections rank immediately after mucopurulent matter. On this head, Swédiaur's experiment may be cited. It is well known that he produced a purulent discharge from his own urethra by injecting liquor ammoniæ into that canal. And lastly, bougies, or any other foreign bodies, by being roughly introduced, may give rise, as has frequently been seen, to a discharge simulating gonorrhœa in almost every respect. We should, therefore, be extremely cautious in framing our diagnosis when called on to decide on the nature of a urethral discharge. Not that the treatment will be materially different in respect of the causes of these discharges, but because questions of the most delicate kind are sometimes put to the surgeon, and he should be very cautious before he gives a verdict which may have a baneful influence on the peace and happiness of families.—*Lancet*.

## DEATH FROM THE ADMINISTRATION OF CHLOROFORM.

By WILLIAM M. BROWN, M.D., Melrose.

On the 10th of August, 1852, I was asked to see Mr. Martin, cattle-dealer, Earlston. Upon visiting him, I found a number of ulcers on the left leg, the surfaces of which, and the surrounding skin, presented a very unhealthy appearance. He had been under treatment by regular medical men, and also by a clergyman who practises the quackery, homœopathy; but with no benefit. As he was anxious for something to be done, I proposed to destroy the surface of the sores, and part of the surrounding skin, with pot. fusa; but as the sores were extensive, and the application of the caustic would be very painful, it was thought advisable to put him under the influence of chloroform, to which I saw no objection. I accordingly went over the following afternoon, and before proceeding to apply the caustic, I gave him the chloroform. He was not easily affected by it, and struggled a good deal. After beginning to apply the caustic, I found he was not sufficiently insensible to pain, and gave him a little more chloroform, which had the desired effect. I then proceeded with the application of the caustic, and was just finishing when I ob-

served a sort of catch in his breathing. I immediately stooped, and on looking at him I saw the mouth and eyes open, the breathing irregular, face pale, the eyes slightly turned upwards, and the pupils dilated. I ordered the window to be thrown open, dashed cold water in his face, tried artificial respiration, but with no effect. In a few minutes the man died. I cannot say how much chloroform was used, as a good deal was lost in the giving of it, but certainly not more than I have repeatedly given. There could be nothing faulty with the chloroform, as it was the same I have been using for some time; and, as a guarantee of its purity, I may mention that it was Messrs. Duncan and Flockhart's. No examination of the body could be procured.—*Edin. Monthly Jour.*

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN, WEDNESDAY, DECEMBER 1, 1852.

### THE LONDON MEDICAL WEEKLIES.

THE following is much too good to be allowed to repose in the niche allotted to "Medical Monthlies" in the Temple of Fame; and therefore do we give it the benefit of our means of circulation, notwithstanding the antipathy of our northern contemporary to "hebdomadals" in general, as well as to those of London in particular. We copy it, too, because we conclude our brethren in the great metropolis have never stumbled on it in the course of their editorial labours, or we should have seen something in the way of rejoinder. There is no use, however, in attempting to ignore the thing, for there it is as fair a challenge as ever was penned; and if the parties assailed sit quietly down under such chastisement, all their bravado must henceforth be taken as so much vapouring after Pistorian fashion; in fact, "blue bonnets o'er the border" floats on the breeze, and there is nothing for it but a speedy retreat or a resolute resistance.

Then we thought of the London hebdomadaries; what good they had done in their generation; and how much evil. How one had thrust itself into notoriety and success by stabbing and throat-cutting; that another, after struggling many years for lingering existence in a virtuous way, had sunk at last into the embraces of a third, the meanest of all; that a fourth had just begun to lower upon the horizon of medicine on an humble scale; that the coming of a fifth had been portended; how they have gradually swallowed up the honest old English Monthlies, left only one languishing Quarterly, and succeeded in so lowering the public taste down to their own level, that in periodical literature there is no longer any profitable investment for capital, whether in brains or gold, except the fleeting leaves of a weekly print; and, most of all, how long it will be before the medical profession of England shall be so imbued with the dignity and purity of true learning, as to starve into surrender those who win their weekly bread by devouring men's characters, and pandering to the insatiable human appetite for scandal, strife, and spoliation. The power now possessed by the weekly medical press has really become a very serious matter, considering by whom it is exercised. Their depressing effect on medical literature and medical ethics raises grave doubts whether the good they have done is not outweighed by the concomitant evil. They claim to be the redressers of medical grievances, the prop and stay of professional independence, reformers in medical legislation, and a great encouragement to medical literature. What is to be said to these pretensions? The profession in England are undoubtedly indebted to them for undertaking a deal of disagreeable and dirty work for the redress of professional grievances. They deserve credit for their promptitude and vigour in assailing—though not always, indeed, in the

best taste—arrogant navy boards, miserly poor-law guardians, selfish assurance companies, greedy medical partners in druggists' profits, impudent quacks of all kinds, obscene advertisers, and the like. Students in London, too, have enjoyed singular facilities for denouncing the poorness of the dinners at St. Bartholomew's College, the opacity of the dressers' heads that encircle the operating-table at Guy's, the slothful progress of Todd and Bowman's Physiological Anatomy, and other annoyances of similar magnitude. At the same time, it may be feared that they have often got very bad advice as to their behaviour at school, from such arbiters of manners and morals. As to the mightier grievances of the profession, such as the miserable state of medical legislation, the close system of medical appointments in the great London hospitals, the patronage of quackery by the public and the legislature, the discouragement of medical science, and of science in general, by our government, the weekly journals may have done their best; but as yet they have effected nothing. And they have done some mischief, too, inasmuch as the insolence of tone and personal abuse, essential to their system of tactics, have steered against conviction men of weight whose minds might have been open to argument and persuasion. In the department of medical legislation it is to be feared that they have obstructed the course of justice by the impracticable nature of the measures they have pertinaciously advocated, and the influence they have brought to bear against every rational scheme of adjustment. We may dispose easily enough of the boast of their partizans that they have been a great support to professional independence. It cannot positively be stated, that any man in our profession has been found destitute of his own share of independence; and it may be safely said that, on the contrary, we see many who, were they to think and act less for themselves, and more by the advice of their betters in judgment and information, would do themselves much good and the world no harm. And if the facility of publication has taught the members of our profession more promptly to resist evil influence and injustice, it cannot be denied that they have been too often led by the same cause to commit themselves both to unnecessary defence and wanton attack. That these contributors to weekly literature have been too often betrayed into a low level of controversy by editorial example, so that the personal and the insolent have become the fashion in controversial medicine; and that the tone of medical ethics has consequently been lowered, thus grievously endangering the favourable position which our profession has hitherto occupied in society in Britain, comparatively with other countries. Those who perpetually sneer at the combativeness of medical men, have no idea of the force of temptation in the ready opportunities of indulgence presented by the weekly medical press. We take it that as human nature now stands, the several professions are all much alike in regard to the natural gift of pugnacity, and the tendency to gratify it. But the varying circumstances of their lives yield various modes of gratification. The soldier alone is trained by a course of severe discipline to store his for use on legitimate occasions. Lawyers expend theirs in sham-fight; exhorting their bile on the clients, or sometimes on one another in shape of their clients, and with the singular privilege of having an umpire on the bench to look on, and stop the combat when it becomes unsafe. Divines have periodical opportunities of exhausting their animosity legally, usefully, and uncontradicted, upon sin and sinners in general. But medical men have no artificial outlet for their share of combativeness. Their professional relations supply frequent cause of quarrel, but they have nobody to assail except one another; they have no other way of doing so but in downright earnest; they have no authoritative umpire to regulate the lists for the duello; and instead of this, they have three or four hebdomadaries sitting like so many "succubi" at their elbows, tempting them to commit the sin of wrath, recording its first overboilings, and thus binding them down to the consequences for ever. It may be asked—Why do the editors of the weekly journals admit into their pages so

much personal contention, which in their hearts they must condemn. Listen to the answer of one of them who puts to himself the question why he does not reject what he disapproves of. "If such were to be the rule of our policy, the *Lancet* would soon become an insipid, worthless production—the mere vehicle of puffing and vapid twaddle." In short, by the contrary course, the sheet is enlivened, and pays. Of all the pretensions put forth on behalf of the weekly medical journals, the most groundless is, that they encourage medical literature. On the contrary, they have degraded it. Their main peculiarity, besides the promotion of strife, scandal, and personality, is the countenance they have given to a third class literature, composed of cases, lectures, and hospital reports.

The mania they have created for this description of authorship is inconceivable. In the *Lancet* for March 22, 1851, a list is given of communications, which want of space compelled the editor to postpone; and it amounts to the appalling multitude of 118. The list consists of 7 lectures, 34 hospital reports, 30 cases, and 44 dissertations. It is very plain, however, that all England could not supply authors able and willing to furnish the fourth part of that amount of materials worthy of being rescued from oblivion. There is, in the first place, no greater load on medical literature than the undigested heaps of solitary cases, to which these periodicals have given birth. No one can over-rate the value of well-described cases, when they present any novelty, or illustrate any point in practice not yet sufficiently established and elucidated. But the great majority of the detached cases in the weekly press are without any point to illustrate; most of them exhibit an utter ignorance or disregard of similar facts which had appeared again and again before; and not a few have no other merit than that they superfluously illustrate well-established generalisations which may be found in any good systematic work. If the authors of such trivialities would read before they write, they might save their pen and ink. The so-called Hospital Reports of the weeklies are even worse. There is not perhaps a more difficult branch of medical authorship, or one requiring greater opportunities of study and more varied qualifications, than a well-digested hospital report. But forsooth, the editor of the *Lancet*, on the 22nd of March, 1851, had no fewer than four-and-thirty more than he knew what to do with! Were hospital physicians and surgeons to make it a habit themselves to study, methodise, and comment upon the cases of a season, and favour the world with reports framed on such a basis, their disinterested exertions would be everywhere acknowledged with gratitude, and would doubtless raise the standard of medical literature and learning. But it is a farce to entitle as hospital reports the productions which appear under that name in the weekly periodicals, and which are seldom anything else than solitary cases, often too without point, without novelty, and even without any better authority than that of the young penny-a-liner who composed them. As for Lectures, we had occasion to digest the Clinical ones to some purpose not long ago, and nothing more need be said of them. The lectures of a systematic kind have been now pretty well exhausted; and, looking back to them, it is not easy to see how they differ either in nature or utility from well-known pre-existing independent works on the same subjects, or how they have any pretensions in point of quality to equal consideration.

The department of original dissertations, the most important branch of journalism for the literature of medicine, must, of course, present inequalities in all periodical works. But it is very plain that a great proportion of those in the weekly journals exhibit signs of hasty publication; and few will stand as works of reference after the lapse of two or three years. They seem in general intended for temporary, and not for permanent monuments of the industry of their authors; and it is greatly to be feared that their object has been not so much to advance medical learning and practice, as to serve for an advertisement to bring the authors' names before the public. It is a remarkable coincidence that, contemporaneously with

the spread of weekly journalism, there has been in this country a great decrease in standard works of original research. We fear that matters have reached this point in London—that a man can scarcely now advance into professional practice, unless he advertise himself by entering into competition with the crowd who scribble for the weeklies,—that, when he does so succeed in attaining a respectable position in his profession, it is not until he has thus naturally enough acquired a distaste for the toil of medical authorship; and that consequently he ceases to write when most competent to instruct by his writings. We may trace more than one biography through these successive phases.

Add to all this the intolerance of the weekly tyrants for everything better than themselves and their partizans, their base usage of the heads of the profession for at least a quarter of a century, their furious and unreasonable antipathies, their uncompromising advocacy of their own favourites for the time being; and no wonder can arise that in the higher walks of our profession there shall now exist a disinclination to take the same active share as formerly in contributing to the literature of medicine. In the days of buccaneering, when some band of pirates had boarded a vessel down on the Spanish main, they either made the crew walk the plank, or clapped them in irons under the hatches, and then, dressing themselves in the cocked hats and laced coats of the officers, they strutted on the deck with all the air of legitimate possession. Just so have our brethren of the southern metropolis been treated by the weekly periodicals, which, during the last thirty years, have gradually acquired an ascendancy no less complete, than despotic and injurious. They have silenced the good men of standing and reputation, knocked down and abused any man who ventured to question their authority, and thrown a shield over the folly and presumption of their own creatures. Do we see no chance of escape from such miserable thralldom? Yes, we do. And what is more, we believe it is from us the poor sufferers are most likely to get assistance for their emancipation. The piratical crew constantly endeavour to keep their prisoners in the dark as to what is going on in the world around them, and to make them believe that the power of their master is proof against all attack. But if we can manage to let a little light shine down into the gloom of their dungeon, we may awake some spark of hope in their disconsolate breasts; and, reminding them that where there is a will there is a way, we may perhaps rouse them to make the effort requisite for setting themselves free. They will then make a rush to the arm-chest, shoot the man at the wheel, hoist the old standard of independence, and, giving three cheers for the good old cause of truth all over the world, again pursue the course which has been so long and disgracefully interrupted.

"Thus said the captain to his gallant crew:  
Down with the black flag, up with the blue!  
Fire on the maintop; fire on the bow!  
Fire on the gun-deck; fire down below!"

—*Edinburgh Monthly Journal*.

## THE DISPENSARY ACT.

### A STARTLING RESULT.

THE following letter and that which it has elicited, announces a fact which at this hour of the day will scarcely be credited. Whether in any other union such a confession of insolvency has been made we know not; but that in even one the Surgeon of a Dispensary should receive no payment for a year is monstrous; and in a union, too, in which a noble Lord talks so lightly of "the doctors":—

GENTLEMEN,—I beg most respectfully to state to you that the Athlone Board of Guardians have never as yet paid any portions of their salaries to the medical officers of the Athlone Dispensary District; and I believe the medical officers in other parts of the union are similarly circumstanced. I am now performing the duties of this dispensary for upwards of a year without receiving a single shilling during that period for my services to it. Of course this communication has re-

ference only to the period I have acted under the new act. Now, in the third quarter, I would not even now stir in the matter, but that it has to-day come to my knowledge that the board within the last few days passed a resolution that they would pay nothing till certain debts were liquidated; so that the period at which we may be paid our miserable stipend would appear to be quite indefinite. Under these circumstances, I respectfully ask of the Commissioners to request of the board that our salaries be forthwith paid.—I remain, &c.,

GEORGE HETHERINGTON.

Popr-law Commission Office, Dublin, Nov. 13, 1852.

SIR,—I am directed by the Commissioners for administering the Laws for the Relief of the Poor in Ireland, to forward to you, to be laid before the Board of Guardians of Athlone Union, the enclosed copy of a letter which the Commissioners have received from Dr. Hetherington, one of the medical officers of the Athlone Dispensary District, Athlone Union; and, in reference thereto, I am to call the guardians' attention to article 19 of the General Rules for the Government of Dispensary Districts under the Medical Charities Act, which declares that the salary of each medical officer of a dispensary district shall be payable by the board of guardians quarterly (that is to say, to the 25th March, 24th June, 29th September, and 25th December, respectively), and I am to request that the guardians will take steps for the immediate payment of the salaries of the medical officers of the several dispensaries in the union, in accordance with the above article, if they have not already done so.—By order of the Commissioners,

W. STANLEY, Secretary.

To the Clerk, Athlone Union.

Mr. Murtagh said that at present there were no funds to pay the medical men. The bank had refused to cash any more cheques until the balance of their advance was paid up. There was still £500 due to the bank, which would be cleared off this week.

From this, as well as from much more that we see and hear, we come to the conclusion that little hope remains of a voluntary compliance by the Guardians with the requirements of the act; and that sooner or later the Commissioners must resort to compulsory measures, however embarrassing such a course may prove. Here is a Board of Guardians repudiating their obligations altogether, while elsewhere the same is done in degree by assigning salaries little more than nominal. In truth, there is little difference between a refusal to pay anything for an article and a refusal to pay what will purchase it. To tender a Surgeon fifty or sixty pounds a year for attendance on the poor of an extensive dispensary district, where as much more, or even half as much, cannot be realized by practice, differs little from tendering a promise to pay with no intention of keeping it. In our last, we hinted at the possibility of such a state of the law being in operation as may disable the Commissioners from coercing the Guardians; but if any such prevails, the sooner an amendment of the statute is obtained the better. Neither time nor exertion should be wasted on any attempt to extort relief from the Commissioners, if it appears that they are unable to afford it; every effort should be devoted to such a test of the determination of the Guardians in every union in Ireland as will prove that nothing but compulsory legislative provisions will secure proper medical relief for the poor.

### THE CASE OF BOURNE v. COX.

We copy the following announcement to inform our readers as to the result of these proceedings which involve many considerations to which we may have to refer hereafter:—

Although we have not received the official Report of the Council of the Bath and Bristol Branch of the Association, we understand that Mr. Cox has withdrawn from the Association, and has thus, of course, stopped all further investigation into his conduct. We have already expressed our sentiments upon this painful subject so fully, that there is no necessity to do more than express the hope, that by a rigid course of upright professional conduct, he may regain that

status which he has now (we hope for a time only) lost. Whilst on this subject, we beg to draw attention to the letter of Mr. Cole, which certainly, if attended to, would obviate much of the odium which the public now sprinkle on us with no unsparing hand. If the profession could only agree upon a scale of charges suited to the varying aspects of medical life, this might, though not easily, be avoided.—*Prov. Jour.*

Just so. All the virtuous indignation indulged in against Mr. Cox should be vented on the system and not on the man. We give the pharasaical gentlemen who so feelingly deplore these peccadillos of their sinning brother very little credit for sincerity, and we thank the writer of the following for his honest expression of opinion on the subject:—

The appearance of the "Amended Draft of the proposed Medical Bill" in the pages of your journal, and your invitation for communications respecting it, reminds me of having hitherto neglected to direct your attention to a monstrous abuse peculiar to the medical profession, for which it does not in my estimation provide a sufficient remedy. I allude to the practice of charging high prices for medicines as a remuneration for professional services. Clause 23, indeed, empowers registered persons to recover reasonable charges for advice, visits, and medicines, and clause 24 prohibits any other person from doing so; and this is all very proper and desirable, and would seem necessarily to lead to a discontinuance of the old system. But why leave to chance that which might so readily be reduced to certainty—why not prohibit a practice that is in every respect so objectionable? If medical men will, or must, supply medicines to their patients, being empowered by law to recover for professional services, it surely can be no hardship to require them to supply those medicines at the druggist's price; there need not be two prices for the same thing, and if the druggist's price is to be regarded as the fair market price, I would have such to be the only price recognized by law. And suppose it should result that medical men, when properly paid for their professional services as a separate item, should be able to supply medicines for less than the druggist's present charge, it may be no loss to the public to discover that their friends the druggists have hitherto made more free with their pockets than fair dealing could in all cases justify. There is no doubt that medicines may be supplied for less than the generality of chemists and druggists now charge for them, and that medical men may be able to supply them at a very low price, without any disadvantage to themselves, when properly paid for their professional services. I would not advocate the supply of medicines gratuitously, but in common honesty they should be supplied at a reasonable profit, and not, as heretofore, at double, treble, five, or ten times as much as they are worth. A few additional words in clause 23 would accomplish my purpose, and at once effectually annihilate one of the greatest evils the profession has hitherto had to deal with. You may possibly argue that the clause as it stands is calculated ultimately to do this. I admit that such ought to be its effect, but am unwilling that so important a result should be left to chance. Besides there would be this advantage likely to arise from the prohibition—it would clearly demonstrate to the public the necessity for the change of system, and by placing our professional services in their proper and legitimate position, tend much to enhance the status of the profession in public estimation. And if it be objected that the profession will soon cease, after the passing of this bill, to supply medicines to their patients altogether, I meet the objection by the assurance, that in small country towns and rural districts this will be found for the most part impracticable.—*Mr. Cole in Prov. Jr.*

But it seems that this view of the case, as adopted by us, is held to be a libel on the General Practitioners of England, and we are denounced for it by a journal which would fain be considered their champion. The *Lancet* tells its readers that we "never lose an opportunity of propagating slanders upon the gentlemen in general practice in England," and that we "display our ignorance and malignity in reference to the case under discussion." Well, if denouncing the practice of drugging and drenching patients to trump up a bill be a slander on the General Practitioners, then are we guilty; but when we see, as we here do, the very organ of the respectable portion of these

practitioners doing the very same thing, we tremble not for the consequences. Then as to the offence of Mr. Cox in the case before us, we cannot see anything so very wonderfully heinous in it. His crime, in fact, is not that he charged the patient twenty guineas for the job, but that he did not do so *selon les regles*. If an Irish Surgeon took a guinea a day for twenty days from a young gentleman labouring under gonorrhœa, who would say wrong he did? Mr. Cox acted very imprudently, and, as it appears, illegally, in meeting the emergency as he did, but those who denounce him do something of the same kind every day of their lives; and the *Lancet* will discharge its duty much better by telling them so than by treating them to a chapter of its blarney. Then as to any society erecting itself into a court for the trial of any of its members under such charges, we doubt very much the propriety or prudence of such a step. We can tell them a judge and jury might take a view very different from theirs, and very little to their consolation. After all, it appears that Mr. Cox attended this person from the 16th of June to the 20th of July, and paid thirty visits, supplying forty bottles of mixtures, and fifteen powders; for which he had to seek payment on the deck of an emigrant ship. He made the most of the case, and that's all.

## CORRESPONDENCE.

## THE MEDICAL CHARITIES ACT.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—Expecting to have seen since my last to you something from “One of the late County Secretaries” to sustain his “highly honourable men” in the inconsistent manner they have acted, I did not notice the observations of “Medicus,” who came to the rescue of the other two correspondents, “The Secretary” and “Subscriber,” sooner. I thought it might be better at first not to notice him at all, as it would appear he desired the subject of the appointment of two dispensaries ought to be left to the ratepayers and the medical attendant, and that the notice of it should be moved from the Press altogether. In this I disagree with him, and believe it to be a subject for the profession to consider, that there ought to be one uniform principle to guide the Poor-law Commissioners in their appointments, and if not the sooner the legislature should interfere the better. Does not “Medicus” well know if such matters were left to the ratepayers, how they would act, as committees often force appointments on them contrary to their wishes.

If “Medicus” would for one moment reflect, he would not compare infirmaries, jails, fever hospitals, &c. &c., to dispensaries, as in the former all the duties of the medical attendant are in one place, while those of the latter are extended over a large tract of country.

As “Medicus” seems to know the particulars of the case, and the large districts to be attended to, he will please recollect, if convenient to do so, that the visits paid under the old system were confined to an area of some two or three late Irish miles around each dispensary, and never beyond that boundary, except receiving some small fee, or under pressing private influence; but under the Medical Charities Act, the medical officer must visit every part of his district, no matter how extensive. He might plead as an excuse under the old being out of his circle, but dare he refuse under the new on pain of dismissal.

I am a little surprised when “Medicus” was enumerating all the recommendations of the “appointed,” he did not put in that he was a first-rate bookkeeper, and wanted a sleeping partner; for you know, Mr. Editor, these qualifications are indispensable for a dispensary medical officer, one for keeping correctly the intricate books, and the other for a successful midwifery practice.

There may be an occasion for noticing the other remarks that are in the letter of “Medicus,” when the “non-elected” or the “disappointed” may show he acted in the most honourable way, and in concert with the appointed, regardless of the insinuations of “Medicus.”

There is one remark more before I am done, and that is, “Medicus” has extended the districts to more than 260 square miles to be attended to by his “young and active” friend. As he asserted that the “disappointed” lived fully fourteen miles from parts of the district alluded to, then deducting one from fourteen would leave thirteen, one mile being the distance of the residence of the non-elected from the district.

In conclusion, I again reiterate, let there be no pluralities of dispensaries.—amply remunerate the medical officer for each, but impose on him no duties which he cannot efficiently discharge, and let one uniform principle guide the “highly honourable men,” the Poor-law Commissioners, in their appointments; for if they had not acted inconsistently, I would have been saved much trouble, and your space perhaps more profitably filled. Thanking you for your courtesy, I am yours,  
A CONSTANT READER.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—Under the above heading have appeared in your journal from time to time for the last twelve months, various editorial and epistolary articles treating, each after its own fashion, on the merits and demerits of the act in question, as well as on the liberal and illiberal spirit adopted in different parts of Ireland in its administration.

You, Mr. Editor, began by declaring that “the labourer was worthy of his hire,” and that after considering the question calmly and dispassionately, you came to the conclusion that “£100 per annum ought to be the *minimum* that a dispensary surgeon should accept, or be offered in ordinary sized districts;” and, again, that “if the districts were excessive, and the salaries inadequate, a remedy for such injustice should be formed.” Then follow your correspondents, conveying to you, and all concerned, the intelligence that, so far from your *minimum* being the fixed standard in ordinary sized districts, not more than half the sum was given in districts of excessive dimensions, and that the said demi-allowance had been sanctioned by the Commissioners, the grand expectations of the profession from their construction of the 8th section of the act to the contrary notwithstanding. Again, the correspondence varies. At one time it is complaining of the number of books and statistics to be kept (which, however, in my mind, are neither difficult to be filled nor in the least troublesome to any man who may be properly paid for keeping them); at another time we find defeated candidates for office (low as the salaries are), complaining of their successful opponents, and charging them with being pluralists.—a term which (we may calculate) was equally applicable to those gentlemen before the present act ever became law, as it has become now (as I suppose) by their reflection to the appointments in question. And here let me ask, Mr. Editor, by way of parenthesis, how many of us, worth a groat, that are not pluralists in some sense or other of the word? The infirmary surgeon with his jail; the workhouse medical officer with his workhouse or dispensary, or mayhap both; the Dublin professor with his university or college chair, and his hospital also—*inter alia*—are surely pluralists as much as the country practitioner with his two dispensaries, whose position and long services have entitled him to these appointments; and yet no man ever dreams of saying that any of the former should give up one of his appointments to meet the wishes of his supernumerary and expectant neighbour, who may be anxious to get it. Away, then, with those murmurings against our more successful brethren, unless indeed that success may be attended with such a glaring departure from all rule and practice as hinted at in the case alluded to

by "A Fellow of the College" in your last impression; which case, if the particulars connected with it be as stated by him, he is bound by his obligations as a Fellow to lay bare and expose before the public.

But to return from this well or ill-timed digression, and to sum up. From all I have heard and seen of the various grievances the profession is labouring under from the operation of the Medical Charities Act, it strikes me that the all-important and the most intolerable, because the most unjust, is the grievance of excessive districts and the inadequate remuneration given for the performance of the duties connected with such districts; and that in any movement to be made by the profession for the redress of those grievances that are supposed to exist in the working of the act, the removal of this—or, I should say, of these two—should be paramount with them beyond all other consideration. The removal of these two grievances! But how is that to be done? "That is the question."

The members of the Medical Charities Committee, who carefully scanned each clause of the act, and who, no matter what may be said to the contrary by parties who never contributed in the slightest degree to forward the cause themselves, spared neither time nor trouble in their endeavours to make the act a useful and fair one; and who invariably consulted the first lawyers in Ireland on those doubtful points in which the interests of the profession were at stake, relying on the professional integrity of the Commissioner that was to be taken from our own ranks, and the powers that he would be enabled to *justly* wield in behalf of the profession and the sick poor, fancied that the interests of both were accordingly secured. When they came to consider the 6th and 8th sections of the act, by which the reader may perceive the Commissioners are empowered, "if to them it appears necessary," or "if they see occasion," to abolish the two grievances aforesaid—viz., excessive districts and inadequate salaries.

The Medical Charities Committee were, however, disappointed in their expectations, and the profession now plainly see that, however apparently clear the words of an act of parliament are, they are liable to two versions; one as diametrically opposed to the other as black is to white. As, for example, the medical profession all over Ireland say that the Commissioners have the power by the aforesaid recited sections of the act, to do them and the sick poor justice (if they so desire); the Commissioners, on the other hand, say "No." But I very much fear that they want the will to find out the way; and I but too well know that poor-law boards of guardians (generally speaking), so far from having it in contemplation to better the condition of their medical officers, are in a great many instances seriously thinking of making it worse (see report of the proceedings of the Ennis Board of Guardians, always foremost in the work of destruction).

We have, therefore, nothing to hope from "the powers that be," as the law at present stands; and that being the case, it is our duty to consider a feasible remedy for the grievances we are labouring under. I, for my part, have been for a long time of opinion that as long as the salaries of the medical officers of the poor are made payable out of the poor-rate, so long will they be limited in amount, and disproportionate to the duties exacted; and entertaining that opinion, I have been during the late agitation of this subject the persistent advocate for payment to the dispensary surgeon out of the Consolidated Fund; and I am as firmly convinced as that I live, that until that consummation is brought about, the poor-law guardians of the country will not (generally speaking) give fair or adequate salaries to these officers. I say "generally speaking," because there are a few honourable exceptions in the country, where the medical officer receives a fair and reasonable remuneration for his services. In my own neighbourhood, one man is allowed £80 per annum in a district with an area of 23,000 acres, and a popu-

lation of only 5432 inhabitants; while in the adjoining union there is only £50 given in a district with an area of 52,000 acres and a population of 14,000 souls; and, to make bad worse, there is more destitution and *more* sickness in one electoral division of the latter districts than could be found in the entire union in which the former district is situated; exhibiting a disparity intolerable in the relative positions of the respective officers.

You, Mr. Editor, express a hope that if the surgeon satisfies both rich and poor by the successful discharge of his duties, he cannot fail to be enabled to exercise such an influence as will secure to him his rights. That may be, in some instances; as in the few honourable exceptions already alluded to, but as a general rule it denies its applicability. In the very district alluded to above, and in which £50 per annum is only given, the first act of the committee of management at their very first meeting was to pass a unanimous vote of thanks to the medical officer for the efficient and successful manner he had discharged his duties under the old system for the last fifteen years, and expressing their confidence in his skill and knowledge for future operations. And yet, although every one at that meeting knew that this gentleman received £80 per annum under the old system for a district about half the dimensions of the present one, there was not one amongst them to raise his voice against the inadequacy of the salary allowed by the guardians and sanctioned by the Poor-law Commissioners! I, therefore, repeat that until we are paid out of the Consolidated Fund (to which we, as officers of the public, have every right), that portion of the 8th section of the act which empowers the Poor-law Commissioners to do us justice will be allowed to remain a dead letter.

But it may be said, as it has been before said to me (particularly by such as expected appointments under the act, and who did not in consequence wish to ruffle the temper of the dispensers of patronage), that the thing was impracticable, unattainable, and, consequently, that we should not be looking for what would not be given, or would not be listened to, &c. This I deny altogether. I deny that it is a subject to which any, and especially the present Government, ought, or would, turn a deaf ear. The readers of the Press, at all events such of them as are politicians (and who are not), cannot but remember that some two or three years ago, the present Chancellor of the Exchequer declared in his place in parliament, that all salaries then payable out of the poor-rate, ought to be made payable out of the Consolidated Fund; as a relief to the landed interest from the pressure of taxation, and are we to be told that now, when in office, he would refuse to take the matter into consideration if called upon by the medical profession all over Ireland to carry out the principles laid down by himself when out of office as fair and just, particularly now that he must eschew protection and make some amends to that party for his unavoidable I ask, could he confer on them than to relieve them from the abandonment of their causes and what greater boon, might payment of the fixed charges of the poor-law establishment.

To shew those who may even yet differ with me on this subject that I do not stand alone in the views I have formed in reference to it, I will, with your permission, give the following extract from a communication which I received on the eve of the last general election from one of the candidates of my county, in reply to certain queries put to him by me as to his political creed. "First of all," he says, "with regard to the poor-law, I entirely agree with you and those who hold similar opinions, that the fixed charges on the establishment should be defrayed from the Consolidated Fund; for the burdens, unfairly and partially weighing upon us, an equivalent should be conferred arising out of the general wealth of the country, and not merely assessed on the landed interest. I really am much obliged to you for reminding me of this omission. The fact is, that my ad-

dress was written in great haste, or I would have enlarged very considerably on the subject of the poor-laws generally."

"When I add that these views and opinions have been given expression to by one of the ablest and most talented representatives that Ireland ever had, and that with him originated some very important amendments of the poor-law as it at present stands, I hope the subject will no longer be considered impracticable by my professional brethren, but that they will take it up as the most feasible method whereby they can obviate the difficulties they are labouring under at present, and remove or remedy the grievances which they are suffering from the operation of the Medical Charities Act."

"Should there be a general meeting of the profession, as I understand has been suggested by that sterling and purely disinterested champion of the rights of the profession—Dr. Kingsley, of Roscrea—I shall make it my business (D.V.) to attend such meeting, and there explain my views more fully as to the manner in which they can be carried out fairly and justly towards all by adopting a *maximum* and *minimum* salary in proportion to the extent and population of the districts and the duties to be performed, &c."

"Should such meeting not take place, I will, on a future occasion, take the liberty of trespassing on the columns of the Press, and of conveying therein those views to my professional brethren for their adoption or rejection, as to them may appear fit.—Mean time, I have the honour to be, your obedient servant,

A MEMBER OF THE LATE MEDICAL CHARITIES COM-

MITTEE, AND COUNTY SECRETARY.

Nov. 24, 1852.

P.S.—Since the above was written, the Press of the 24th came to hand, and I rejoice to find by it that the subject of payment to the poor-law medical officers, out of the Consolidated Fund, has been alluded to, both by yourself and your London Correspondent, corroborating thereby the views I have formed on the subject. There are other points of importance also introduced into your leader which I may take an opportunity of advertizing to hereafter. For the present, I will content myself with expressing my regret that the Poor-law Commissioners (if they are really disposed to act fairly or justly by the profession, of which disposition I have serious doubts) did not run the gauntlet with the Limerick Board of Guardians advertized to by you. The result would either affirm or negative the powers supposed to be conferred on them by the act; and if the latter, they would then be in a position to call for more definite and less doubtful powers. Let every county in Ireland follow the example set them by Tipperary and Limerick, and it would answer the purpose as well as a suit at law with the board of guardians of the latter county.

November 26, 1852.

#### ABUSE OF CHEMICAL CERTIFICATES—THE BEER PUFF.

A LADY who had been for years in the habit of taking Guinness's stout, recently informed the agent that she was under the necessity of discontinuing it. On his inquiring whether she had any fault to find with the stout, she replied, "Yes, it is adulterated—if it were not adulterated, you would have it analyzed, and publish the certificates; as the makers of bitter beer have done; but you dare not have it analyzed, because you know it is adulterated." Assertions and protestations were in vain, the lady closed her account. The disreputable advantage which has been taken of the strychnia panic as a means of puffing the beer of one brewery in particular, has had a temporary effect on the public mind which is neither creditable to the parties concerned, nor likely in the end to place them in an enviable position in the trade. All the brewers of bitter beer were under an imputation resulting from an unfounded rumour. It was necessary that this should be contradicted, which was done by the publication of the result of a full investigation of the facts of the case, and the quality of the beer from several breweries. Here the matter might have ended. The panic had ceased; the breweries

were in full work, and some of them could not make their beer fast enough to meet the demand. One of these firms, however, conceiving this to be a golden opportunity for a puff, has given the public such a dose of advertisements, and certificates, and correspondence respecting the beer of that brewery, that some innocent persons have been led to suspect that the strychnia rumour was, after all, not so ridiculous and unfounded as it had been represented to be. The question is a natural one—"If all this noise and trumpeting be necessary to clear the character of one brewery, what must be the state of the case with other breweries, the proprietors of which are satisfied with a simple contradiction of the rumour, and then leave their beer to trumpet for itself?" The lady above referred to appears to have come to the conclusion that all beer is either puffed or poisoned, and as Messrs. Guinness and Co. will not condescend to puff their stout, she declines to drink it. Others might draw a different inference, founded on the old maxim, that "good wine needs no bush." Leaving the rival breweries to find their level, we cannot pass unnoticed the injustice perpetrated on the distinguished chemical professors whose names are associated with this system of advertisement. On pumps and posts, dead walls and watering screens, where quacks and impostors plant their puffs, in railway stations, public-houses, and newspapers, hand-bills and circulars, the names of Liebig, Graham, and Hofmann are displayed in large type, in conjunction with the name of the firm which employed them professionally to examine and report upon their beer. If scientific men, in the performance of their ordinary duties as analytical chemists, are to be liable to this annoyance and degradation, it will become necessary for them to be extremely careful to whom they give reports or certificates of this nature. The abuse of chemical certificates is not an unfrequent occurrence, and some chemists habitually refuse on this account to furnish reports in writing, except under particular circumstances or conditions; but we do not remember a more flagrant case than the one before us. The evil will in some degree cure itself; the beer puff has already produced an effect in checking the facility with which such documents can be obtained. In several instances of recent occurrence they have been refused, and it is not likely after what has occurred that men of the highest eminence, whose opinions are most in request, will furnish written reports without some guarantee or understanding that such reports will not be used in a disreputable manner.—*Phar. Jour.*

Some five-and-twenty Physicians and Surgeons, besides four or five "Professors," have lent their names for the purpose here noticed. We cannot blame people in business for seeking such aid, for they do not know that there is anything wrong in it; but professional men who are fully aware of the impropriety cannot be so easily pardoned. The periodical gibbeting of some Dublin Surgeons by the rival Solomons, the spectacle hawkers, has done good service here by deterring others from indulging in such left-handed advertising.

#### TO CORRESPONDENTS.

Dr. H. McC.'s paper arrived too late for this Number (noon-day); it shall appear in our next. So also J. F. K.'s addition. Such matter is always the first set up and arranged. We are at a loss for some hints from London correspondents on the present tactics, objects, and prospects of their medical periodicals. There is a rustling under the straw here, and a fidgety manner there which requires some "private and confidential" explanation.

FELT AND CHAMOIS LEATHER PLASTERS.—The Messrs. Wright and Ewing have introduced a material which is likely to be valuable to patients requiring plasters for bed-sores. It may also be useful for other purposes. It consists of a kind of felt, more soft in its texture than that which is used for hats, and is covered on one or both sides with chamois leather. The plaster is either spread on the leather or on the felt. In either case, it appears to be an application likely to prove serviceable. It may be used for removing pressure from any particular spot, by cutting a hole in the plaster at the part affected.—*Phar. Jour.*

## SUBSTITUTE FOR MERCURY IN SYPHILIS.

M. ROBIN lately brought before the Academy of Medicine of Paris ten cases treated by M. Vicenti which would prove the efficacy of bichromate of potash as an anti-syphilitic agent. From the facts, of which M. Robin gave a detailed account, he draws the following conclusions:—1. Bichromate of potash is now ascertained to be an anti-syphilitic agent. 2. The salt being very soluble, acts without loss in extremely small doses, the treatment being therefore shorter than when mercury is used. 3. Bichromate of potash does not in general produce salivation. 4. The only disadvantages hitherto noticed are nausea and vomiting when the salt is taken fasting; but these unpleasant effects do not take place when the medicine is administered a little time after the digestion of a meal, and especially when it is associated with opium. 5. It is of much use in neuralgia, and though it may produce asthenic effects, it is by no means deleterious. 6. Its exciting properties may render it useful in indolent ulcers, in more or less strong solutions; as also in syphilitic sore throat, in the form of gargle. 7. As the ten patients who have taken the bichromate have not experienced the least unpleasant symptom, even by using very large doses for a protracted period, the new anti-syphilitic agent is now proved to be of greater value than the salts of mercury, which latter may become reduced in the economy, whilst the bichromate is irreducible under the same circumstances, and is so soluble as to be easily eliminated. Two of the above-mentioned cases were treated in 1850 and 1851, and no kind of relapse has been noticed.—*Lancet*.

## SHIRTS CUT BY MACHINERY.

WEBB AND CO.'S

New System of Shirt-cutting by Machinery enables them to produce really First-class Shirts at prices lower than they have ever yet been offered.

Their Eglinton Shirts,

at 2s. 6d., 3s. 6d., and 4s. 6d. each,

are accurately Cut, elegant in Design, and perfectly sound in Fabric.

A large assortment of Fancy Veined Full-dress Shirts always on hand.

## THE TAILORING AND GENERAL OUTFITTING WAREROOMS

are now most extensively supplied with every description of WINTER CLOTHING.

## THE READY-MADE DEPARTMENT

contains an immense variety of

Top Coats, Travelling Coats, Wrapper Coats, Pilot and Frieze Pea Coats,

at 15s., 17s. 6d., and 20s. each,

which, for Workmanship and Solid Value, are not and cannot be surpassed.

WEBB AND CO.,

10, 11, and 12, CORN-MARKET.

## SURGICAL SOCIETY OF IRELAND.

THE Meetings of the Society, for the Session 1852-53, will take place at the Royal College of Surgeons on the under-mentioned Evenings, at Half-past Eight o'clock precisely:—

1852—Saturday, 20th November.

Saturday, 4th December.

Saturday, 18th December.

1853—Saturday, 15th January.

Saturday, 29th January.

Saturday, 12th February.

Saturday, 26th February.

Saturday, 12th March.

Saturday, 26th March.

Saturday, 9th April.

Saturday, 23rd April.

Members who intend to read papers before the Society are requested to inform the Secretaries of their intention a few days previously.

When the Contributor of a paper wishes that the Secretaries should read it to the Society, he will please to forward it to them some days before the Meeting.

CHARLES BENSON, M.D.

O'BRYEN BELLINGHAM, M.D. } Secretaries.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

## THE COMPOUNDING DEPARTMENT AT

## G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &amp;c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

## TO SURGEONS, DISPENSING CHEMISTS, ETC.

SULPHATE of QUININE, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, cap-suled, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.

October 23, 1852.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. Wednesday, December 1, 1852.

## METEOROLOGICAL TABLES.

## PROCEEDINGS OF SOCIETIES.

### SURGICAL SOCIETY OF IRELAND.—Nov. 20.

The first meeting of the Society for the Session 1852-3, was held at the Royal College of Surgeons on Saturday evening, the 20th of November, and was most numerously attended.

Dr. HUTTON, President of the College, in the chair.

The PRESIDENT, on taking the chair, called the attention of the meeting to a circular issued by the Council of the Society, through its Secretaries, explanatory of the nature and objects of the Society, and calling upon the physicians and surgeons of Ireland, whether resident in Dublin or in the provinces, to contribute papers, showing or giving the results of their observation and experience. The President made a few observations on the liberal constitution of the Society and on the extent and importance of its objects, and expressed a hope that the members of the medical profession would fully avail themselves of the opportunities offered, or that the call made upon the members of the profession would be well responded to.

The following is the circular referred to by the President :

Royal College of Surgeons, Dublin.

SIR,—We are directed by the Council of the Surgical Society of Ireland to request your attention to the objects of this institution, and the privileges of its members. It is believed that if these were better known, practitioners throughout the country would more frequently avail themselves of this Society as a medium for communicating to the profession the results of their observation and experience.

The Surgical Society of Ireland was established in 1831 for the advancement of medicine and surgery and the collateral sciences. Its meetings are held once a fortnight during the winter, in the Royal College of Surgeons, on Saturday evenings; the chair being taken at half-past eight o'clock by the President of the College, or in his absence by the Vice-President, or the senior member present.

Communications are then read by the author, if present, or by the Secretaries or any other member to whom he may entrust them; after which the subject of the paper generally,

or any particular point, at the discretion of the chairman, is discussed. But no discussion of any paper is permitted unless desired by the gentleman who contributes it.

A short-hand writer attends to take a report of the proceedings, which is afterwards submitted for correction to a sub-committee of the Council, and then published in the DUBLIN MEDICAL PRESS.

The entire expenses of management are borne by the College, so that no subscription or fee of any kind is required from its members.

Fellows of the College are ex-officio members of the Society, and can have the certificate of membership on application to the Secretaries. Licentiates of the College are elected on being proposed by one member of Council, and seconded by another. Physicians and surgeons of other colleges are eligible by ballot.

We beg leave to enclose a card, showing the nights of meeting for the ensuing session, and will be happy to take charge of any communication you may be disposed to make.

We have the honour to be, sir, your obedient servants,

CHARLES BENSON, M.D.,  
O'BRYEN BELLINGHAM, M.D., } Secretaries.

### CASE OF ANEURISM OF THE DESCENDING PORTION OF THE THORACIC AORTA: WITH REMARKS.

By R. MURNEY, M.D.

Dr. MURNEY said, the pathological specimen which he had the honour of laying before the Surgical Society, was taken by him from the body of a patient on the 8th of the present month. The gentleman consulted him on the 1st of last June. He stated that his illness commenced six weeks previously by a pain and sense of tightness across his chest, which became worse at night, and each night progressively increased. When he went to bed he slept rather comfortably for two or three hours, but after that period was usually awakened by this severe pain and a horror of impending suffocation, so that the remainder of the night was spent in the erect position and in great agony. He told me that he had spent an active life, fond of gymnastic exercise, and that his habits were temperate, age 61. He invariably enjoyed good health, with the exception of an acute inflammation of the right eye, for which

he was attended by the late Mr. Colles. The eye was saved, but with permanently dilated pupil, and double vision when the left eye was closed. On examination, I found him in the following state: Pulse 70; heart's action normal, both as to impulse and sounds; no other sound or impulse to be heard in the chest, either anteriorly or posteriorly, or tenderness on pressure; the chest on percussion gave rather a dull sound under the clavicles; there was also feebleness of respiration, but no râle of any kind. Here I was divided between two opinions—viz., that it was either a gouty rheumatic attack of the heart, or inflammation of the lining membrane of the aorta, and perhaps an incipient aneurism. I abandoned the former opinion, in consequence of his having told me that there was no gout in his family, his habits of life being active and temperate, the character of the pain being such as I have described it, progressively increasing and recurring every night. I adopted the latter opinion, and treated him accordingly. I prescribed for him a mixture composed of sedatives and anodynes, which relieved him considerably. He was enabled to spend the entire night comparatively free from pain. He recovered his former spirits in a day or two, and expressed himself quite happy. I then determined on giving him a chance of mercury, and bringing his system under its influence as quickly as possible, as I considered the disease still to be confined to the lining membrane of the aorta, and as there were not sufficient physical signs to lead me to the conclusion that an aneurism had as yet formed. The mercury acted for a time very beneficially. I also kept a blister open over the sternum for a fortnight, at the end of which time he expressed himself quite recovered, and determined on going to his house of business in Liverpool, where he remained a month, with complete immunity from the pain. At this period the former symptoms again returned. He put himself under the care of some medical men in Liverpool, who took a different view of his case: they considered his disease to be connected with derangement of his stomach and liver. Remaining under their treatment for about three weeks without benefit, he returned to Dublin. He sent for me. I found him much changed in appearance, his countenance expressive of anxiety and pain, much emaciated, and like one suffering from disease of a malignant character. He told me that his manner of life, notwithstanding my cautions to the contrary, had been, while in Liverpool, as active as usual, regularly attending to his business and regimen as when in health. I examined him. The former symptoms, so far as the heart and pulse were concerned, little altered; but at the upper part of the sternum there was a strong, well-marked single impulse after the second sound of the heart. No other sound to be heard in any other part of the chest. This impulse was perceptible both to the hand and to the stethoscope. The jugular veins were also distended. On applying the stethoscope over the upper part of the sternum, there was well-marked stridulous breathing, quite indicative of pressure on either bronchi. He also complained of dysphagia, which he referred as commencing at the upper part of the larynx. At this period the difficulty of swallowing was equal, either of fluids or solids. There was a pulsation to be observed in the carotid and also in the radial arteries, resembling in appearance regurgitation through the aortic valves; but those valves were able to discharge their functions, as indicated by the second sound. At this period Dr. Stokes saw him in consultation with me. He suggested an addition to the anodyne remedies, and the application of a few leeches to the fourchette of the sternum. About two hours after the application of the leeches, after slight exertion, and exposing himself to a draught of cold air, he got a violent spasmodic attack, with difficulty of breathing and great stridor. I was sent for, and I found him walking from room to room, with the windows raised and the doors opened. He was gasping for breath, and presented a frightful appearance, eyes glistening and prominent, lips blue, face livid, and covered with a cold clammy perspira-

tion. The longer he was exposed to the draught of cold air, the stridor and difficulty of breathing became worse, and the anxious efforts by which he endeavoured to overcome these were most distressing to behold. I immediately conducted him to a warm room, excluded the cold air, applied hot sponges to the larynx and trachea, and took about two ounces of blood from his arm, all of which gave him instantaneous relief. Several paroxysms occurred before his death, and it was only by the frequent application of hot sponges and the use of antispasmodics and anodyne medicines, that he was enabled to avert their more frequent occurrence. He suffered extremely about the third or fourth of these attacks, and became quite faintish; the extremities cold; heart's action very feeble; the impulse already described at the upper end of the sternum not to be discovered: the pulse at the wrist not to be felt. After each of those attacks, the impulse diminished, and gradually disappeared, the stridor and difficulty of breathing became greatly relieved, thereby showing that the cause of the pressure was diminished, and after several repeated attacks, similar to those I have described, on the 6th of this month, he sank, exhausted and completely worn out.

Eighteen hours after death, I made a post-mortem examination of the body. On raising the sternum, the lungs appeared not at all capable of filling the cavity of the thorax, but free from any appreciable disease. On opening the pericardium, I found two or three ounces of serum in it. The heart enlarged, soft, and flabby. The aorta dilated, and had a thick rough feel, both in its ascending and transverse portions. Behind the root of the lungs, corresponding to the fifth and sixth dorsal vertebrae, I found a large oval tumour, as large as a goose egg, situated in the posterior mediastinum, its long axis transversely. In front of it lay the aorta to the left side, the right bronchus to the right, and the œsophagus in the middle intimately adhering to the tumour. This tumour was firmly confined down to the vertebrae by the contracted adhesions with the surrounding parts. In the left pleura there was a considerable quantity of coagulated and fluid blood. I removed the parts by cutting across the aorta and œsophagus below the tumour, and dissecting the tumour from the vertebrae. The bodies of the vertebrae were eroded. I found atheromatous deposits on the free surface on its lining membrane on the posterior wall of the descending portion of the aorta. Corresponding to the tumour there was a well-defined circular opening, about the size of a half-crown. I then slit up the œsophagus. I found on the posterior wall of it also another opening, about the size of a shilling, communicating with the tumour. The right bronchus was flattened. The tumour was composed of fibrine and coagulated blood. The position of the tumour mechanically obstructed the vena azygos and thoracic duct, which, I think, sufficiently accounts for the great wasting and emaciation. In detailing the symptoms, I forgot to mention that the voice was natural. It is easily accounted for by the recurrent laryngeal nerves not being interfered with.

Now, sir, on reviewing this case, I think it is more or less instructive, when you consider how long a time intervened from the commencement of his illness until the unequivocal signs of a tumour manifested themselves. This period extended over a space of three months. It is true you had the characteristics, pain and burning sensation and paroxysms, returning at night, but certainly no evidence of eccentric pressure, no stridor, or dysphagia. Could an aneurism have existed when I saw him, and have lain dormant, without giving any physical signs of a tumour, or was it owing to its situation, concealed as it was by the heart, pericardium, and roots of the lungs, and firmly confined to the vertebrae by contracted adhesions? But you might have observed those signs posteriorly. Perhaps it is more probable that the tumour was made up of fibrine and coagulated blood, its cavity being small; consequently, the quantity of blood entering proportionally small, thereby rendering it impossible for the tumour to give either impulse or sound; and that it was only when the patient made some imprudent exertion, the sac suddenly became

enlarged, and thereby admitted a greater quantity of blood, which produced a sufficient impulse, to be communicated along the aorta up to the sternum, which I heard at the period I have already mentioned. I confess doubts frequently arose in my mind as to the accuracy of my diagnosis, because similar pains might have been produced by a cancerous deposit on the posterior mediastinum, implicating the nerves of that region. I wish to have this paper as practical as possible. I shall select a few of the symptoms that are to my mind quite pathognomonic of the existence of an aneurism—the burning character of the pain radiating from a centre, the paroxysms recurring at night, disappearing during the day, and occasionally the complete immunity from pain. This peculiarity attends no other disease that I am acquainted with.

I thought that this case was unique in the absence of the double impulse and the double sound in thoracic aneurism. But I find a paper in the *Dublin Quarterly Journal* of August, 1846, by the late Dr. Greene, very able and practical indeed, in which he gives twelve cases of thoracic aneurism presenting different characters as to impulse and sounds. In the seventh case there was neither impulse nor sound, but this was a case of true aneurism occurring at the junction of the ascending with the transverse portion. This case which I have related resembles an aneurism of the abdominal aorta, as far as position and physical signs are concerned. Dr. Bellingham, in a very able series of papers, published in the 19th Volume of the *DUBLIN MEDICAL PRESS*, satisfactorily explains the different phenomena of sounds and impulses in thoracic aneurism. At some future period, perhaps, I may have an opportunity of returning to this case, as I have a suspected case of aneurism at present under my observation.

Dr. HENRY KENNEDY thought the Society was much indebted to Dr. Murney for the very interesting case he had just brought under their notice, and he begged to offer one or two remarks with reference to the connexion between the symptoms during life and the appearances found after the death of the patient. Dr. Murney seemed to think that the symptoms were all attributable to the aneurism; but his own impression, looking at the history of the case, was, that they were in a great measure due to the state of the heart. It was a fatty heart, with a dilated ventricle; and this was a state of parts that often produced symptoms similar to those which were observed in Dr. Murney's case, in the first instance. With respect to the sounds and impulse, he thought it might be questioned whether they were not attributable in this case to the dilatation of the aorta; for the aneurism itself was placed too low down (as far, he believed, as the fifth or sixth dorsal vertebra), and was too closely adherent to the latter to be able to communicate any perceptible impulse to the top of the sternum. In his opinion, therefore, the symptoms in question were referrible to the state of the heart in the first instance, and to the dilatation of the aorta in the second.

Dr. MURNEY said he could not agree in the opinion advanced by Dr. Henry Kennedy, that it was a fatty heart. There was, to be sure, some fat upon it, but not enough to entitle it to be termed a fatty heart, although it might possibly be one in the transition stage. No doubt, the aorta was considerably dilated, and to this circumstance he attributed the character of the pulse. The opinion he gave in his paper was a mere conjecture of his own, and perhaps Dr. Kennedy's explanation was the more correct of the two.

PRESIDENT—May I ask Dr. Murney whether the respiration was impeded in any part of the lung?

Dr. MURNEY—Yes; there was considerable stridor, and the respiration was very feeble all over both lungs.

Dr. BANON observed that the question put by the President was one of much importance as regarded the diagnosis of these aneurisms. Their obscurity of character at the period of their commencement, was acknowledged by every one who had been in the habit of treating them. In the early stage it was exceedingly difficult to diagnose

them with any degree of accuracy, but there were two symptoms very commonly met with by which the diagnosis might be greatly assisted—namely, the dyspnoea, which always occurred when the bronchi were interfered with, and the deep-seated dysphagia which usually accompanied aneurisms arising from the aorta, or from the origin of the innominate. He remembered a case which he laid before the Society on a former occasion, where a small aneurism pressed partly on the œsophagus and partly on the right bronchus; the symptoms being somewhat similar to those described by Dr. Murney in his present communication. The patient, who was a lady, suffered much from dyspnoea and dysphagia. A small space, corresponding to the position of the second rib, on the right side of the sternum, was dull on percussion, but everywhere else the sound on percussion was equally good as at the left side of the chest. On applying the stethoscope, the respiration was observed to be very feeble, and after some days it could not be heard at all at the right side of the chest, except over the point corresponding to the aneurism. The lady ultimately died, and on opening the thorax, the aneurism was found pressing partly on the œsophagus and partly on the right bronchus. The obscurity which attended these cases was well known, and it was not at all improbable that the aneurism existed in Dr. Murney's case before he was able to diagnose it.

Dr. BENSON drew Dr. Murney's attention to a sign particularly mentioned by Dr. Hope—namely, that when an aneurism was situated behind the heart, the latter was thrown forward with a kind of “jogging motion,” which was often mistaken for an evidence of hypertrophy of the organ. He would be glad to know whether this jogging motion was noticed by Dr. Murney?

Dr. MURNEY—No; there was nothing of the kind. I repeatedly examined the heart, and the sounds, though rather weak, were always natural. Nor was the heart thrown forward in the slightest degree.

Dr. POWER inquired to what part the patient referred the peculiar sensation connected with the dysphagia?

Dr. MURNEY—To a point corresponding to the cricoid cartilage; for which reason the man imagined the disease to be located in that region.

Dr. POWER said he had asked the question because at this moment he had under his care a patient affected with a symptom of a similar kind; and it is worthy of remark, that he attributes all his suffering to the region of the cricoid and thyroid cartilages. He was much inclined to think that an aneurism will, ultimately, be diagnosed in this instance.

Dr. HENRY KENNEDY said it was a curious fact that aneurism, very low in the chest, sometimes gave rise to dysphagia, which the patient referred to the cricoid or thyroid cartilages.

Dr. HARGRAVE said, with reference to the fact of pain of a burning character being felt by Dr. Murney's patient in the centre of the chest, and radiating from this point outwards, that cases were upon record, and that one had come under his own observation, in which there was but one symptom present during a period of nine months—namely, intense pain, which was referred to the inferior angle of the scapula, and which never ceased, either by day or by night. The lungs were healthy, the respiration was unimpeded, nothing abnormal could be detected within the heart. He examined the body after death, and found a thoracic aneurism extending from the third as far down as the fifth or sixth dorsal vertebra. The bodies of the dorsal vertebrae and the intervertebral cartilages were eroded, and yet the only symptom which the man complained of was the pain to which he had alluded, and which could not be alleviated either by the administration of opium internally or by the external application of moxas, blisters, or any other remedies that could be thought of at the time. The more frequently cases of this kind were brought under the notice of the profession, and discussion elicited upon them, the better it would be, not only for the public but for themselves, and for their reputation as practitioners.

## MEDICAL SOCIETY OF LONDON.

## DIPHTHERITIC EXUDATION IN SCARLET FEVER, ETC.

Dr. WILLSHIRE inquired if any member practising on the Surrey-side of the river had noticed any peculiarity in the present epidemic of scarlatina. It had never been his lot to observe scarlet fever so fatal. It was not, however, peculiar only for its fatality, but for the strong tendency which prevailed to a diphtheritic exudation in the throat. This tendency to diphtheritic exudation also existed in other diseases now prevalent. It took place on a blistered surface, on sores on the nates, &c., and in some cases on the mucous membrane of the vagina. He had seen two cases of the latter, occurring in young women at the Surrey Dispensary. Did this peculiarity occur in the higher situated parts of the metropolis? He might mention that in many cases of scarlatina the patient succumbed early in the attack; in others from the sequelæ; but he had seen no case in which the ulceration of the throat had extended to the internal carotid or jugular vein. In most of the cases, ammonia and bark were required from the first, with the application of the nitrate of silver to the throat.

Mr. BROWN had had no experience of the disease on the Surrey-side of the water, but he had noticed in his practice that in cases of scarlet and low fever there was a great tendency to diphtheritic deposit on the mouth, tongue, and throat. He had seen some cases of the disease affecting the mucous membrane of the vulva. No doubt the cause was atmospheric. These patients required support with wine and tonics from the commencement.

## CASE OF NIGRITIES.

Mr. CANTON drew the attention of the Society to a preparation of a portion of skin which he had removed after death from the lumbar region of a girl, aged 16, and which presented the peculiarity of being deeply coloured by a deposit of black pigment in its cuticular layer. This colouration was found in large and small patches, separate or associated, in various parts of the trunk, one shoulder, and the gluteal regions. All these dark patches were connected with an eruption on the skin of a rupial character, and they for the most part surrounded the incrustations; the colouration of them was most pronounced in those situations from the neighbourhood of which the crusts had disappeared, and where the skin on which the latter had formed was left whiter than usual. The patient had been removed, a short space of time before she died, from the "dark arches," as they are called, in the Adelphi, and was received into St. Martin's Workhouse, in a state of filth, poverty, and disease. She had led a very depraved life, and stated that she had sometimes cohabited during one day with as many as twelve or fourteen persons. The cause of death appeared to be a slowly-increasing decline of the vital powers, which was accompanied by œdema of the extremities, and a collection of a small quantity of fluid in the abdomen. At a post-mortem inspection, the contents of the large trunk-cavities were found generally healthy. The fimbriated ends of the Fallopian tubes were spread over the ovaries, and firmly adherent to them through the medium of dense, short, fibrous bands. The recto-uterine cul-de-sac was filled up by similar, but longer bands, intersecting one another in all directions, and tying the back of the uterus to the forepart of the rectum: these appearances being altogether very significant of the habits of life of the patient. No internal structures exhibited marks similar to those on the skin. Mr. Canton remarked, that a close examination of the coloured portions of the skin showed the pigmental deposit to be present in the deeper set of cells of the cuticle more especially—as in the negro race; and referred to in a case mentioned by Professor Quekett, in his lectures on Histology (p. 210), where the superficial cells on the skin below the right eye of a young woman contained granules of pigment; and this epithelium "was capable of being brushed off with a camel's hair pencil." A remarkable instance of this abnormal occurrence is described and figured by Mr. Teevan, in the *Medico-Chirurgical Transactions* for 1844. A case is recorded by Le Cat (and quoted in Mayo's "Pathology," p. 233), in which a lady at the seventh month of pregnancy

had her countenance by degrees become so disfigured, that being "naturally of a fair complexion, she presented the appearance of an alabaster figure with a black marble head." This colour disappeared two days after her confinement, with a profuse perspiration, whereby the sheets were stained black. The child was of the natural colour. In the following pregnancy, and even in a third, the same phenomenon appeared in the course of the seventh month; in the eighth it disappeared: but during this month the lady became subject to convulsions, of which she had an attack each day. A curious instance was related to Mr. Erasmus Wilson by Dr. Sarti, wherein an Italian peasant, aged 50, having unluckily been concerned in a fray, was fired upon and put in danger of his life. The shock caused a severe illness, and three months afterwards his skin gradually darkened, until it became quite black. The change was first perceived on his cheeks, and thence extended over the entire body, being greatest on the inner sides of his breast, the inner sides of his legs, and the hands. In his "Portraits of Diseases of the Skin," Mr. Wilson has recorded an instance of partial blackening of the skin, producing a mottled appearance. The seat of the change was the legs, and the cause, constitutional disease.

Some discussion took place on the nature of the discoloration, and on the question whether it was congenital or not.

Mr. HUNT could not throw any light upon its pathology. He had seen cases of the *lepra nigricans* of Willan, in which, after the scabs had fallen off, dark brown, but not black spots, had been present, which lasted for life. He (Mr. Hunt) thought, in these cases the carbon of the blood had been deposited, but why or wherefore he would not attempt to explain.

It was now suggested by Dr. CAMPS, that the case of Mr. Teevan, reported in the *Medico-Chirurgical Transactions*, was, an imposture; but this suggestion was shown not be correct, as the case had been observed and watched by several medical practitioners.

Dr. CHOWNE inquired if, in Mr. Canton's case, there was any reason to suspect that the discoloration was congenital; and he referred to a case which had occurred to the late Dr. Well, in St. Thomas's Hospital, of a young woman, the daughter of white parents, who had congenital black spots over her body.

Mr. CANTON did not know if the discoloration in this case was congenital; he had given the history of it as far as he was acquainted with it.

Dr. ROUTH alluded to the cases of two young ladies in Edinburgh, who, during an epidemic, had become affected with black spots over the face. He had seen a case in which black spots presented themselves over the entire body of an old gentleman who was affected with disease of the liver. The spots diminished whilst he was taking the iodide of potash, but he died worn out by the internal disease.

## BELLADONNA AS A PROPHYLACTIC OR CURATIVE AGENT IN SCARLATINA.

A long and somewhat desultory discussion then took place on this subject, having had its origin in a question asked by Mr. White. Mr. Brown had found belladonna to invariably arrest the poison of scarlatina. Mr. Dendy had no doubt that its administration as a prophylactic mitigated the throat symptoms very materially; but Dr. Rogers had abandoned its use after a fair trial, from observing that many persons had the disease after the administration of the medicine. Dr. Radcliffe had used it extensively; but the very worst cases of scarlet fever which had fallen under his notice were those in which belladonna had been given as a prophylactic. Mr. Roberts had tried it in a great number of cases, but had abandoned it, from his complete disappointment in its effects. Dr. R. M. Glover remarked, that the trial of belladonna on a great number of cases, in the hands of some of the most careful observers, had ended in its failure; and Dr. Snow, Mr. Clarke, and Dr. Chowne contended that the negative evidence brought forward in support of the efficacy of the "remedy" weighed as nothing in the balance against the positive facts which had been adduced against it.

## ORIGINAL COMMUNICATIONS.

## A WORD ON PHTHISIS.

By HENRY McCORMAC, M.D., of Belfast.

THE excessive attention paid to the morbid anatomy and treatment of phthisis, with the comparative neglect of the Etiology, even in the immortal works of Louis and Laennec, has long afforded me matter for surprise and reflection. From one-fourth, to upwards of a third, is the common ratio, as contrasted with the entire mortality, of the mortality in phthisis. Surely this appalling destructiveness calls for further comment, and further effort, on the part of the profession, than it has ever received. How trifling are the ravages of cholera, compared with those of tubercle, yet the bare announcement of some epidemic outbreak evokes, and justly evokes, the flashing of a thousand pens. I do not desire that epidemics should be minded less, but that phthisis should be minded more. In spite of the ignorance of the public, the occasional apathy of members of the profession, medicine, as a science, an art, has deserved well of the world. Medical science has greatly stayed, if it have not entirely checked, the ravages of small-pox. A similar task, and, I am persuaded, an equal triumph, awaits it, in respect of phthisis. This monster scourge must be abated, if not entirely put down.

The people, "the public," as we are wont to style them, know, in general, about as much of the nature and causes of phthisis, as they do of the inhabitants of the planets or the denizens of the invisible world. And *inter nos*, be it said, the "faculty" do not think so much of the sources of phthisis, as, if so inclined, they might do. Can any one pretend to say that the treatment of this ruthless malady, on curative indications be it understood, is not to the last degree, nugatory and unsuccessful? Will but one physician, or surgeon, or surgeon-apothecary, among the prodigious host who profess and practise the healing art, seriously undertake to affirm that he has, in a single instance only, removed, by art, the more or less complete tuberculous infarction of one lung, more rarely both lungs, which, in the very great majority of instances, subsists in phthisis? And if he cannot do so, will any one state the *cui bono* of the tons upon tons of fish-oil, to say nothing of respirators and other nostrums, which oppress the stomachs, but lighten the pockets, of myriads of unhappy sufferers? The fact is, we must look to the etiology!

"But, sir, how am I to live? What will etiology do for me?" quoth the general practitioner? We cannot, in a matter of such moment, look merely to the interests, however important, of general practitioners, any more than to those of fish-oil and respirator manufacturers. The interests of wailing, quailing, distressed humanity, must here take precedence. Medicine, before anything else, is a science, an art, not merely a trade. It were better we should all of us go to the wall, were such the alternative, than that phthisis should continue its ravages, disgraceful to us, as they are disastrous to the world. But to the point! To the point then.

The whole etiology of phthisis, at least such is my humble, but most intense conviction, resides in the respiration of air befouled, and thereby rendered unfitted for healthy respiration. Of course, there are hosts of accessories, foul feeding, foul clothing, damp, physical inertia, the respiration of vegetable, more especially mineral, dusts, and despondency. But even these, short of the continued operation of foul air, would not, to any considerable extent, entail phthisis. The momentous, the deathly experiment goes on, continually, on every hand. We have only to open our eyes, to collate the experience of a thousand observers, to be aware of the stupendous fact, that foul air, and foul air only, not climate, else, not position, not habit, not even hereditary influence, practically speaking, is the one, only source of a scourge, as I must again repeat, disgraceful indeed to art, but most disastrous to our kind!

I would call upon the profession, then, upon colleges of medicine and surgery, as upon the humblest, since the hum-

blest (for Jenner, let us recollect, was but a general practitioner) can here do good service, to investigate this matter, and if they can coincide with me, as I feel assured that upon inquiry all of us may do, to stir heaven and earth to free their species from the most terrible, because most ceaseless, most insatiate, and at the same time most unnecessary and uncalled-for, of all inflictions.

Belfast, November 22, 1852.

## ELEPHANTIASIS ARABUM OF THE RIGHT INFERIOR EXTREMITY.

## SUCCESSFULLY TREATED BY LIGATURE OF THE FEMORAL ARTERY.

By J. M. CARNOCHAN, M.D.,  
Professor of the Principles and Operations of Surgery in the  
New York Medical College.

CHARLES ROLLER, of lymphatic temperament, and short stature, *ætat.* 27, born in Aix-la-Chapelle, merchant, left his home in December, 1849, and landed in New York in February, 1851, went thence to Connecticut, where for eight months he worked in a factory, standing during his hours of labour, thence to Virginia, where he worked on a farm for about six months, at the expiration of which period he was taken with fever of an intermittent character. Up to that time he had always been in good health.

During the fever the inguinal glands became swollen and painful, the swelling and pain extending in the course of the femoral vessels as far as the knee. The pain was followed by swelling and redness of the thigh down to the knee. From the knee, the pain and swelling continued to extend downwards as far as the toes, being at this time confined chiefly to the portions of the limb along the course of the saphena vein, and also of the posterior tibial vessels. The redness and tumefaction here, in the thigh, was preceded by deep-seated pain. The tumefaction of the limb continued to increase; while at the same time febrile exacerbations occurred at intervals, varying from two to six days. After a period of about six weeks from the commencement of the disease, the fever entirely disappeared, and by this time also the pain and redness had entirely ceased; the limb, however, remaining hard, swollen, and rough, and presenting in a marked degree the peculiar characteristics of elephantiasis arabum in the chronic period of the disease. From this time forward, the hardness and intumescence gradually increased, and the limb became so cumbersome that the patient was obliged to give up all business, and confine himself chiefly to a recumbent posture. In this condition, the patient left Virginia for the purpose of seeking medical relief at the New York Emigrants' Hospital, into which he was admitted on the 15th of January, 1851. The appearance of the patient upon entering the hospital was somewhat emaciated. He had no febrile symptoms, and the chief difficulty under which he laboured, arose from the enlarged and hypertrophied condition of the right inferior extremity.

The limb was enlarged from the toes to within a short distance below Poupart's ligament. The thigh, although enlarged, was not much indurated; while from a short distance above the patella, downwards, the limb presented a dense, hypertrophied, hard, scaly, shapeless mass.

The morbid condition of the tissues pervaded the foot and toes, there presenting groups of tuberculated growths. The circumference of the limb around the ankle was nearly as large as that of the calf, measuring fifteen inches and a half, while the circumference of the calf measured nineteen inches and a half. The patient was put under treatment upon entering the hospital. The recumbent posture was enjoined, and for some time various discutient lotions were used. Bandaging was resorted to, with frictions of ung. potass. iodid.; the iodide of potassium being also prescribed internally. At times also the limb was painted with strong tincture of iodine, local and general baths were used, regular bandaging of the limb, from the toes upward, being the while carefully observed.

This plan of treatment was perseveringly adhered to from the 15th of January to the 22nd of March, a period

of a little over two months, without any amelioration. Having thus tried, without success, the method of treatment most approved of, I proposed to place a ligature upon the femoral artery, with a view of changing the morbid condition of the structures supplied by the branches of this arterial trunk. A consultation was held, and my proposition was acceded to as preferable to amputation, the usual alternative resorted to in this stage and extent of the disease. Accordingly, on the 22nd of March, 1851, I secured the femoral artery a short distance below the origin of the *arteria profunda*. Upon exposing the femoral artery, this arterial tube was found to be changed, so as to present an appearance somewhat like the colour of the aorta of the ox, and to be larger than the common iliac of the human subject. In consequence of this appearance of the artery, after some hesitation, I applied the ligature, preferring to do this rather than to expose the external iliac, of the soundness of which I could not be certain.

The ligature came away from the femoral artery on the eleventh day, accompanied by secondary hæmorrhage, the occurrence of which I had expected as probable. For the purpose of arresting the hæmorrhage, the external iliac artery was secured by ligature by Dr. Hosack, who happened to be on duty at the time in the hospital. The external iliac was found to be about the size of the brachial artery. This for a time apparently had some influence upon the hæmorrhage; but on the following day, bleeding was again renewed from the orifice in the femoral artery with as much profusion as ever. The hæmorrhage was now restrained by the prompt application of a tourniquet on the cardiac side of the bleeding orifice by the house-surgeons, Drs. Thompson and Smith. This even failed to stop permanently the hæmorrhage, and the blood recommenced oozing copiously at intervals. The patient was now sinking fast, and the ligature of the common iliac or amputation at the hip-joint, appeared to be the only resources left. But the hæmorrhage now being evidently reflux, it was suggested to apply the tourniquet, so as to produce compression on the distal side of the bleeding orifice; this was done, and was followed by a complete cessation of the bleeding.

From this time (April 4, 1851), the house-surgeon kept an instructive record of the case, which record I have now before me. For several days, the pulse ranged from 115 to 108; the dressings were carefully attended to, and light diet prescribed. On the 12th, the leg was found to be considerably reduced in size, and the ligature of the external iliac came away. On the 17th, brandy and quinine, with good nourishment, were ordered. On the 1st of May, finding the leg more reduced, and the lower wound healed, I ordered tincture of iodine to be painted on the leg, and the bandage to be continued. I also ordered a solution of chloride of soda to be used as a wash on the upper wound, which continued to discharge freely.

The patient now went on gradually improving in strength and appearance, and left the hospital in the latter part of June, completely cured of his malady. At this date, sixteen months after the ligature of the femoral artery, the patient is in robust health, and presents no indications that the disease will return.—*New York Journal of Medicine*.

This man had a narrow escape indeed, but the result is highly instructive. Is there any such thing to be found in New York as a proper apparatus for compressing arteries, or is such a contrivance as unknown there as in London and Edinburgh? We put it fairly to Dr. Carnochan, whether his patient should not have had a trial at least of compression before he was subjected to "deligation"?

THE Marquis of Argenteuil, once a great sufferer from stricture, left at his death sufficient money to found a prize, to be given every six years by the Academy of Medicine of Paris, to the author of the most practically useful improvements in the treatment of urinary diseases. M. Reybard of Lyons has obtained the prize, which this year reaches the sum of £480.

## SECONDARY HÆMORRHAGE TREATED BY COMPRESSION OF THE BRACHIAL ARTERY ON BELLINGHAM'S PRINCIPLE.

By ROBERT L. MACDONNELL, M.D.,  
Surgeon to St. Patrick's Hospital, Lecturer on Surgery,  
St. Lawrence School of Medicine, &c. &c.

THE following case which occurred in my hospital practice some years ago, is not totally devoid of interest, and the principle upon which it was treated may not prove useless, nor do I believe the result was different from what might have been attained in many similar accidents, had the same method of treatment been pursued.

If, by the avoidance of an operation, the safety of a patient and the cure of his disease can be equally as well accomplished as by its performance, it is considered a great improvement in modern surgery, and he who has discovered a plan by which recourse to the knife is avoided, is justly esteemed a more accomplished surgeon, and a more successful cultivator of our science, than he who, however skillfully he may perform an operation, does not perhaps do it with more adroitness than hundreds of others; and in most cases is but a servile follower of some master-mind who first originated the operation. Hence it is, that the modern system of treating aneurisms by compression, has placed the names of its authors in the foremost ranks of surgical pathologists, and as I believe that the plan may be advantageously employed in many instances for the arrest of hæmorrhage from wounded arteries, I bring forward the following example, as the most striking I have met with, to illustrate this point of practice.

It has been very much the fashion in some quarters to depreciate any attempts at the simplifying of surgery, and one distinguished practitioner, for whom no one entertains a higher opinion than I do, whilst he himself has shown the most striking instances of this very improvement inconsiderately, as I believe, has thrown a slur upon the attempts of others, in furtherance of that object. I allude to Professor Syme's depreciation of Dr. Bellingham's discovery—in expressing which, upon one occasion, he declared, that such a procedure as the cure of aneurism by compression, should only be adopted by surgeons who "*were not capable of practising the higher departments of their art*." In justice to Mr. Syme, it must be stated, that he considers deligation of the femoral artery for the cure of popliteal aneurism, a much more simple procedure than the treatment by compression—an opinion in which few surgeons, either on this or the old continent, will coincide. Even then at the expense of being charged with having missed an excellent opportunity for tying the brachial artery, I have great pleasure in laying the following case before my readers, for I doubt not, many a brother practitioner, called to severe injuries, so common in our rural districts, will be better pleased to learn how to arrest secondary hæmorrhage from the upper extremities, by a simple and easily applied apparatus, than if he were given some new landmark for finding the brachial artery itself: so, without further comment, I shall proceed to the detail of the case.

Thomas Foley, aged 28, a ship carpenter, was admitted into the Montreal General Hospital, September 7, 1847, under my care. It appeared that a few minutes before admission, he had a quarrel with another man, who made an attempt to stab him in the chest with a bowie knife, and in his effort to ward off the stroke of the knife it entered and completely transixed the left forearm, and reached the chest, inflicting in this latter situation but a trifling incision. The knife was held in dagger fashion, and the stroke was a back-handed one, so that in completing the sweep of the weapon, the muscles on the anterior part of the forearm were divided from the radius and ulna, as far as from the head of the ulna, where the knife entered, down to the wrist. Before admission into the hospital, the arm had been bound up by the bystanders with handkerchiefs and other cloths to staunch the bleeding, which had reduced the patient to a state of extreme collapse. The dressings were carefully removed, a tourniquet

having been previously applied over the brachial ■ a precautionary measure. On examining the wound, the ulnar nerve was found to be *sliced* in a couple of places but not divided, and a similar injury had been sustained by the ulnar artery, *flute-hole* apertures occurring in three places, from which blood spouted out. Ligatures were placed upon the vessel, both above and below these openings, and it was remarked, that though the most superior incisions of the artery were first attended to, and the bleeding from them was effectually stopped, deligation of the vessel at these points did not seem to arrest, to any extent, the bleeding from those at the distal end of the wound. We were obliged to put on a ligature wherever a bleeding point showed itself. The edges of the wound were brought together, a bandage carried round the arm from the fingers up to the shoulder, and the usual general treatment prescribed, directions being given to have the hand and forearm supported upon a pillow, and a tourniquet to be kept applied over the brachial, and to be tightened on the first appearance of bleeding. *The radial artery did not appear to be divided*, and its pulsations were perceptible when examined in the usual situation.

September 10th: Until last night, everything proceeded favourably, but about eleven o'clock the house-surgeon, Dr. R. P. Howard, was called to the patient's bed side, in consequence of a sudden burst of hæmorrhage; the tourniquet was tightened and I was sent for. On my arrival I opened the wound, and found a couple of small arteries from which blood escaped, but it did not appear that all the bleeding proceeded from these vessels, for it continued after they were tied, and seemed to ooze from the general surface of the wound. It now occurred to me to apply *two tourniquets over the brachial, and to regulate the amount of pressure in such a way as to diminish, without completely arresting, the stream of blood, for the radial being untouched, and (as proved by the occurrence of the hæmorrhage), the inosculation being free and numerous, we had little to fear from cutting off a portion of the arterial supply.* Accordingly one tourniquet was tightened until a perceptible change was detected in the volume of the radial's pulse, and this was found quite sufficient to control the bleeding from the wound, which was then dressed with lint dipped in turpentine, and the arm was as before bandaged up. The patient was desired to alternate the pressure of the tourniquets, so that when one became painful, the other was tightened and the first one relaxed. The instruments were kept applied for nine days, and he left the hospital fourteen days from that of his admission with the perfect use of his arm. Owing to his dread of bleeding, he allowed the upper tourniquet to remain tightened so long upon one occasion, that slight ulceration ensued.

This patient presented himself before the Clinical Class of St. Patrick's Hospital last winter, and gave the following account of his subsequent state. For some months the arm remained weak, though he was able to follow his employment; he suffered from pain along the course of the ulnar nerve, and from contraction of the ring and little fingers, which gradually disappeared on his keeping them extended upon a small splint. The cicatrix of the wound is now *thirteen* inches long, from which circumstance, the reader may form a correct idea of its original dimensions. He now states (what he kept a secret whilst in the hospital), that on one occasion, becoming tired of the pressure of the tourniquet he relaxed it, but hæmorrhage came on in a few hours, and he was obliged to resume the pressure, which he carefully kept up, till the wound had nearly healed.

The reader will perceive, that the principle upon which the foregoing case was treated, is precisely the same as guides the surgeon in the employment of compression in aneurisms, *the flow of blood was diminished, but not interrupted, and enough for maintaining the nutrition of the arm was carried on by the radial and its branches, and by the interosseal, for I rather think the secondary hæmorrhage proceeded from the twigs of this latter vessel.* Be that as it may, the result of the treatment shows that in many cases secondary hæmorrhage may be arrested without cutting down upon the primitive trunk, and though the

practice may have been adopted by others, I am not aware that any one has preceded me in the application of the Dublin mode of compression in cases of secondary hæmorrhage, and I cannot but conceive it as one, perhaps not the least important or valuable, of the applications to which that inestimable principle is capable of being adapted.—*Canada Med. Jour.*

#### ICE AS A LOCAL ANÆSTHETIC.

By W. A. BERRY, M.D., Washington, U.S.

I PROPOSE to make known to the many readers of your valuable journal the application of a new local anæsthetic agent, which probably is not familiar to a large majority of them. This agent is applicable to but a very limited part of the frame, but its efficiency is such as to cause its use in all like cases. I refer to the local anæsthetic effect of ice in the removal of the nails of the toes or fingers. This most painful operation is disarmed of all its terrors by this simple means, and the patient witnesses it with as much composure as his operator. The agent was first made use of in the wards of M. Velpeau, during the past summer, in Paris, by one of his internes, and afterwards successfully applied by himself in a number of cases. The ice is powdered finely and mixed with a sufficient quantity of salt; next enveloped in a thin cloth, and the two phalanges of the great toe or thumb enveloped in it; the application should not be continued over five or six minutes, this time being sufficient to produce the most perfect anæsthesia. M. Velpeau proceeds with the operation in the following manner: Immediately upon removing the ice, the nail is divided in its length with a common sized bistoury from its free extremity to the root, then seizing each half successively with a strong forceps, it is removed with a moderate jerk. The frequent necessity for the performance of this operation, and the great pain attending it when removed under other circumstances, is sufficient to cause its universal application by the profession. M. Velpeau directs the application of compresses of cold water to the part during the first twenty-four hours; and the simple cerate dressing for a few days is all that is required. It may be objected that the reaction under the application is such as to prevent its use; I will simply say that of the six patients that I saw operated upon by M. Velpeau, no such accident occurred to any one of them; and to the one case in which we applied it but a few days since (and which has suggested this communication), we have reason to believe that the agent is free from any unhappy results. The simplicity and efficacy of this piece of minor surgery, and the so frequent necessity of some surgical interference in these cases, has induced me to send you this communication.—*Phil. Med. Examiner.*

#### EARLY OPERATION FOR HARE-LIP.

DR. A. L. PIERSON, of Salem, in common with the best surgeons of the day, advocates the early performance of the operation for hare-lip, and in a late number of the *Boston Medical and Surgical Journal*, furnishes some observations in favour of that practice:—"On the 2nd of February, 1851," he says, "I was called to operate on a child in Marblehead, born with a hare-lip. The late Dr. Briggs, who knew my preference in favour of an early operation, sent for me immediately on the birth of the child. I performed the operation when the child was but twelve hours old. I operated in the usual manner, with scissors and sutures. My method is to use three simple sutures, one far up in the nostril, one at the epithelium of the lip, where the cutis terminates, and one midway between these. The wound healed at every point by the first intention, and the child was put to the breast on the sixth day, which was as soon as lactation was established. On the 22nd of May, 1852, a healthy male child, with a hare-lip, was born in my practice. It had a cleft palate and superior maxillary bone, and the left alæ nasi more than usually dilated, flattening the nose and giving a hideous expression to the countenance. I operated when the child was six hours old. I dissected up the skin very freely, separating the cartilage

from the bone, and then brought the parts together with sutures, taking especial care that the upper one should be sufficiently high up in the nostril. Union by first intention followed, and the child nursed readily in six days. For some years I have been more and more satisfied that operations in surgery are most successful as they approach nearest to the period of birth. In the earliest infancy the recuperative powers seem to be strongest. I have also remarked that the sensibility to pain is less distinctly marked at first, than after a few days. In the last-mentioned case of hare-lip operation, the child actually slept while the lip was being dissected from the maxillary bone. It was formerly generally believed that the earliest infancy was the period when the system was most liable to convulsions. I have been led to doubt this maxim, and to believe that the nervous system is more easily excited, the more its function is called into exercise, and this is certainly not the case immediately after birth. A newly-born child also sleeps more, and when awake is less observant and prone to motions of the extremities, than after a few days of extra-uterine life. The anxiety and unhappiness of the parents, also, are of so much shorter duration as we operate earlier on the patient."

### EUROPEAN SURGERY.

(Extracts from a Lecture by Dr. Mütter, Professor of Surgery in Jefferson Medical College, Philadelphia.)

*Anæsthesia.*—My attention, naturally enough, was first directed to the subject of anæsthesia. I need not, on this occasion, enter upon the history of this purely American discovery. I repeat, "purely American discovery;" for, notwithstanding the attempts made by some to give the credit of this most valuable of all modern improvements in surgery to Europeans, we have yet positive evidence of its being in truth an offspring of the New World. I do not pretend that efforts to mitigate the suffering attendant upon surgical operations were not made long before the introduction of the new process by the inhalation of some sedative agent. In fact, in all ages, surgeons have endeavoured to attain by various measures this truly important end. Thus we read in Middleton's tragedy of "Woman, Beware Woman," published in 1657,

"I'll imitate the pities of old surgeons  
To the lost limb; who, ere they show their art,  
Cast one asleep, then cut the diseased part."

But I contend that we have no authority for supposing that prior to the introduction of ethereal inhalations in this country, any agent of the same class had ever been elsewhere practically employed. It is true that Beddoes and Davy had suggested, and even used, the nitrous oxide gas with the view of producing anæsthesia, but the experiment attracted little notice, and was soon forgotten; and to the American really belongs the honour of having brought to light the immense value of anæsthetic agents in the treatment of painful disorders or the performance of surgical operations. Having said this much in defence of our rights, I may proceed to state in what estimation the measure is held abroad, and a few words will suffice to do this. In England, Scotland, and Ireland, and on every portion of the continent of Europe, it would appear that no surgeon of any grade, high or low, pretends to practise his profession without the constant use of some anæsthetic agent. When I asked my distinguished friends in London and Paris, if they employed the measure with the same degree of confidence as at first, they seemed surprised at the question, and unhesitatingly declared that no surgeon would presume to perform a serious operation without first bringing his patient into a state of anæsthesia, provided always, there was nothing present to contraindicate the production of this condition. While there exists some difference of opinion as to the best agent to be used, there is none upon the great point of the value of the measure in the practice of surgery. The agent usually employed is chloroform—a fluid, first used to any extent by Dr. Simpson of Edinburgh; and it would appear that very few cases of serious consequences resulting from its employment have been met with either in public or private

practice. With us, however, the reports are not so satisfactory; and hence, some, myself among the number, still prefer the original preparation of sulphuric ether, or else a mixture of the two, forming a new fluid called "chloric ether." Attempts have been made to substitute other fluids, but up to the present time ether and chloroform are considered by far the safest and most to be relied upon.

The bromohydric ether, discovered by M. Robin of Paris, has recently attracted some attention, but is not at all in general use.

But general anæsthesia is not alone resorted to. An attempt to obtain a similar condition locally is also a favourite measure. Up to the present moment, however, the experiments with this view have not been as satisfactory as could be desired. The famous "Eau Hollandaise," or "Ether Chlorohydrique Chloré," from which so much was anticipated, seems to have proven a total failure; while the "Frigorific Mixture" of Mr. Arnett has likewise been found wanting in many of the cases to which it has been applied.

I cannot attempt in this place to indicate the method of using anæsthetic agents, nor can I point out the cases most proper for their application. These matters must be left to the general lectures and to the clinic, in which an ample field for observing the practical working of the measure will be afforded you. Before leaving the subject, I may remark, that in France, at least, the use of chloroform or ether is chiefly confined to surgical practice, very few using anæsthetic influence in obstetrics. In Great Britain, on the other hand, it is much employed in both departments of the profession.

*The Microscope.*—The next point of interest to which my attention was directed, was the influence of microscopic observations in surgery. In anatomy and physiology, so much has been gained by the use of the microscope, that I was led to hope that our department had also been enriched through the agency of this most wonderful instrument; nor was I disappointed. In the study of malignant growths, much has been discovered both novel and practically useful. Again, in the examination of secretions, the microscope has proved of great value. For example, we are able to decide in cases of deep ulcer over a bone, by examining the pus, whether or not the bone is diseased. The presence of pus in the sputa can only be detected by the microscope. It is also of great value in the diagnosis of certain diseases of the kidney and bladder. Without it Mr. Quekett could never have made the wonderful discovery that a urinary calculus—a solid stone—is in reality organized; and by its use alone can we ever arrive at a correct classification of tumours. The application of the microscope in surgical pathology, however, is still almost an untrodden field; and he who now determines to enter upon its cultivation, will most assuredly reap a rich harvest of renown for himself, and confer lasting benefits upon humanity and science.

*Wounds.*—The next subject of interest, to which I shall direct your attention, is the manner in which extensive wounds are dressed at the present time in Europe, and you will naturally enough be surprised to learn that in a matter of such vital importance there should exist any diversity of opinion among surgeons as to the proper method of treatment; and yet there is scarcely a point in practical surgery that has elicited more controversy and discussion. The French, with but very few exceptions, still adhere to the original views of some of their older authorities, and unite all extensive wounds by the second intention of Hunter; while the British surgeons, like most of us, adopt a plan directly the reverse, and endeavour to obtain, as far as possible, union by the first intention of Hunter, or simple adhesion. It afforded me no slight gratification to find that the principles I have so often inculcated here, in reference to this subject, should be those upon which the practice of such men as Brodie, Lawrence, Stanley, Guthrie, Travers, Fergusson, Phillips, and others of high reputation, have for many years been based, and I was thus fully convinced of the propriety of attempting, when the case justifies such an attempt, the immediate

union of a wound. I cannot, at this time, present you with the arguments advanced by the French for adhering to the reverse of this treatment, but on a proper occasion they will all be fully explained. From what I could learn, the continental surgeons, out of France, are gradually adopting the modern English and American method; and instead of covering up their wounds with great bundles of charpie, or that filthy abomination, a poultice, apply the lightest dressing, and frequently employ nothing but cold water, as recommended especially by many of the older surgeons, and more recently by Larrey, McCartney, and Liston.

**Traumatic Hæmorrhage.**—In the management of traumatic hæmorrhage, there has been little or no improvement. In fact, surgeons have long since settled down upon the great indications to be observed in such cases, and hence there is but little room for improvement. Forced flexion in wounds of the extremities, however, deserves notice, and may in many cases prove eminently serviceable. This new measure appears first in the "Anatomie Chirurgicale" of Malgaigne, and has been successful in some few cases, especially in one reported by M. Durwell, in the *London Medical Gazette*.

**Syphilis.**—While in Paris my attention was especially directed to the subject of syphilitic diseases, from the circumstance that the highest authority upon this class of affections still exercises his functions as professor in the Hôpital du Midi. Ricord, by birth a Baltimorean, but for many years a resident of Paris, has long since rendered himself famous in the management of the class of diseases just referred to, and I found that his views, promulgated, some of them, many years since, have undergone very little modification. He still uses mercury in primary syphilis, and considers it the only true and safe remedy. The preparation employed is the proto-ioduret, and my own observations agree with his, in establishing this as the best of all the mercurials in the treatment of indurated chancre or bubo. Mercurial fumigation he also recommends in the strongest terms, as a safe and speedy method of bringing a patient under the influence of the specific. In phagedenic chancre, iron is beyond all question the remedy to be employed internally, while mercury here is almost sure to act as a poison. Tertiary syphilis he still treats with iodide of potassium as his sheet anchor, and contends, that to be of permanent benefit, it must be administered in large doses.

**Cancer**, in all its phases, has recently been closely investigated by Muller, Langenbeck, Carmichael, Bennet, Quekett, Walshe, Simon, Rokitsansky, Libert, and others; but I fear much remains to be done ere we arrive at its true origin and proper treatment. No question seems to exist as to our power of communicating the disease by inoculation. If, for example, we mix a little cancerous matter with water, and inject the mixture into the venous circulation of any animal, we to a certainty induce cancerous deposits in different parts of the body, and especially in the pulmonary veins. The truth of this statement has recently been verified by my friend Dr. Leidy of this city, who has succeeded in establishing the disease by inoculation even in cold-blooded animals—for instance, a frog. With respect to some of the various attempts recently made to cure the disease radically, the plans of Jobert, Lisfranc, Dieffenbach, Phillips, and Arnott appear to have attracted most attention. The method of Jobert, which consists in the application of a ligature to all the principal arteries supplying the tumour, and the division of its nervous filaments, seems to have acquired no great reputation, and I scarcely heard it alluded to by the surgeons of London and Paris. The same may be said of the process of Lisfranc, which proposes in cases of superficial cancer in any organ, the removal of the diseased tissue, either with the ligature or knife, leaving the organs upon which it happens to be located untouched. The method of Dieffenbach, Phillips, or Martinet de la Cruse—for all claim the merit of the invention—differs from the ordinary operation in this: instead of allowing the wound made during the removal of the tumour to heal by granulation, which is usually permitted to a certain extent in all cases of exten-

sive dissection, a flap of sound skin is taken from the adjacent parts and brought over the raw surface, so that union takes place, and thus prevents the granulating process. It is supposed by the authors of this plan, that the application of the healthy skin to the surface from which the cancerous mass has been removed, will so change the vital action in the part, that health will take the place of disease, and hence a return of the complaint be effectually prevented. But, unfortunately, experience is against the operation, and if cancer is a constitutional affection, as it often is, it is difficult to imagine that it could prove so useful as we have been led to suppose. I have myself tried the experiment in several cases, but the disease has invariably returned; and I find such to have been the result in the practice of others. The operation will, in all probability, be speedily forgotten, along with a host of other novelties that are fast wending their way to the "tomb of all the Capulets." Mr. Arnott of London has recently revived the method of Recamier, which consists in the methodic and continued application of pressure to the diseased mass. Experience, so far at least, is against this measure; but in hopeless cases—those, for instance, in which the knife promises nothing—it may be employed, as it will serve to satisfy the patient in part, and prevent to a certain degree that terrible sickness of heart that overwhelms a poor sufferer when utterly abandoned by the surgeon. Recently, Dr. James Arnott of Brighton has published some interesting facts which go to prove the value, as a palliative measure at least, of the application to cancerous tumours, of a very low degree of temperature, the parts being in fact frozen, or nearly so. If his statements are to be relied upon, this is certainly a measure deserving the notice of surgeons.

**Pleurisy.**—An operation altogether novel in the disease for which it was practised, has been introduced by Professor Trousseau of Paris, one of the most distinguished practitioners of that city of eminent medical men. Professor Trousseau told me that he has succeeded in relieving several patients who were almost in articulo mortis; and I have myself known it to accomplish the same end. The operation is nothing more than the evacuation of the fluid in cases of acute pleurisy. You are aware that the secretion is here often exceedingly rapid, and unless the lung be relieved, the patient must die of suffocation. When, therefore, you find a patient thus situated, recollect that paracentesis thoracis, promptly performed, will probably afford immediate relief.

**Injection of Joints.**—Some of you are, doubtless, aware of the tedious nature of certain chronic inflammatory affections of the joints, especially of the larger ones. Now, it has been proposed, and the experiment repeatedly tried, to inject the cavity of the joint diseased, just as we would the tunica vaginalis in hydrocele, with some stimulating fluid, with the view of causing a new action in the secreting surface, by which either adhesion would be accomplished, or a check put to the excessive secretion of the fluid. In England I found the surgeons generally opposed to the operation, as one fraught with great danger, but in Paris it seemed to be quite a popular measure. Velpeau and Jobert both advise it, but I must confess that I saw nothing to induce me to join in this opinion. It is beyond question a most serious operation, and has caused the death of more than one unfortunate patient. The fluid used by the French surgeons is the tincture of iodine, and certainly this is much the least hazardous agent.

**Ascites.**—Attempts to cure ascites on the same principle have recently been made by Drs. Dieulafoy, Leriche of Lyons, and Bonnet. Five cases of cure resulting from iodine injections, are reported by the first-named gentleman; and the last gives a history of fifteen treated by the injection of gases, water, iodine, and other fluids, fourteen of which recovered, only one dying. This is certainly most astonishing success, but the practice of others has proved by no means so devoid of risk. In fact, just before I reached Paris, a patient upon whom the operation had been performed perished most miserably.

**Excision of the Joints.**—In diseases of the joints, com-

plicated with serious lesion of the bones, the operation of excision is becoming quite a favourite measure, particularly in England. The head of the femur, the elbow joint, and even the knee, had been removed just before I reached London, and I was told that success followed each operation. This measure is not, however, a novelty, as it was recommended long since by White and Moreau, and has been performed by surgeons both at home and abroad.—*Philadelphia Med. Examiner.*

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, DECEMBER 8, 1852.

### THE MEDICAL CHARITIES.

At the risk of being considered "very tiresome" at the other side of the Channel, or it may be, what is still worse, "very Hiraish," we must again dwell on the subject of our Medical Charities. We are not, however, going to inflict on our readers this day another "leader" respecting the matter, of our own concoction, but one from a provincial paper, which has been forwarded to us by a person anxious to promote discussion to the grievance of inadequate salaries. The article which we copy does not, perhaps, contain any novel view or original argument, but it places on record the prevalent opinion in a particular locality, and displays a laudable anxiety to serve the cause we advocate. We copy it, too, because we are willing to encourage this method of agitation by local agency and the non-medical press. A correspondent suggested to us some time ago the cultivation of this branch of resource; but, except in this way, what can we do? It is for others to work in that direction. If a good article be even now and then inserted in a provincial paper, we will copy it, and in return perhaps our provincial contemporary may copy some of ours. But, then, such articles must be brief, and to the purpose; for we can assure our readers that the author of "Hudibras" was right when he said that "Brevity is very good, if we be or be not understood;" and equally certain that to produce effect the matter should be rigorously restricted *ad rem*. The great Irish agitator of the age never ceased to ding into the ears of his followers his favourite "Who would be free himself must strike the blow;" and we would follow his example, for to say the truth, prospects are not so encouraging as to lead us to hope that we can dispense with any means of relief. Once for all, let us adjure our provincial brethren to cultivate self-reliance, and to put no faith in metropolitan promises. The pensive Dr. STOKES, "sighing like furnace," may tell them, as the man in the song says, "how genteely they died;" and Dr. CORRIEAN may prophesy of "famine and fever, cause and effect," but there it will end. We tell the Surgeons of Ireland they are a host, and that they can wield a weapon if they will, which those who neglect them may little dream of. We are not thinking of small wars with poor-law authorities, much less of any such thing as an assault on any Commissioner, which would be very unjust and very impolitic, but of a systematic resistance to every measure which is unjust or oppressive:—

The position of physicians in many localities under the new Medical Charities Act, involves considerations, which not merely concern the maintenance of the respectability and character of an honourable profession, but also affect even

the most selfish interests of the public at large. According as matters stand, the absolute extinction of the medical body, or its degradation to a state which would be pregnant with the most serious mischiefs, seems certain. The Commissioners of Poor-laws have provided a splendid stimulus to intellectual ambition, in the prospect which an educated man has after a long period of study of receiving £60 a year for the support not only of himself, but of a horse also, such is necessary in country districts for visiting patients. By the time the horse is supplied, it will perhaps be admitted that a very slight margin of income remains for the superior animal. At the goal of an arduous struggle, and as the reward of victory over rivals, the medical man sees this magnificent prize. Who would not be tempted to encounter the continual contact with wretchedness and distress, to brave the fever bed, and to submit to the most loathsome and painful labour, when animated by the idea of this noble recompense? Nay, who would not even endure to be badgered by ignorance, to have his professional judgment subjected to the criticism of presumption, and to be the object of teasing and degrading scrutiny with regard to every instance in which his humane feelings may exceed the limits of a general order, for the sake of such glorious pay? It is not necessary to compare the real and ill-paid humanity of the physician with the highly-remunerated though imaginary services of sinecure parsons, in order to exhibit the relative injustice of the position which the former occupies under the law. A medical man is actually reduced at present to a level with even the humblest pursuits in point of remuneration. Some chance exists of the members of the profession eking out an existence in cities and towns. But in wide rural districts, where almost the whole sick population takes refuge in public relief, and where at the same time vast distances have constantly to be traversed, we can fancy nothing so unjust and unreasonable as their situation. This condition of affairs we consider to be deeply injurious, as well to the interests of the poor as the rich. As regards the former, the physician but too frequently stands alone between them and official hardness; and we have known repeated cases in which the firmness and humanity of that officer, backed by his professional authority, flung a shield over the wretched victims of destitution. A medical man ought not to be denuded of all relation to a gentleman in the scale of salary. The person whose duty is to save life ought not to be placed on a grossly unequal footing to those who are appointed to save rates, but whose labours really tend less to that end than his. It is utterly impossible to secure zeal on such terms as those to which the conduct of the Commissioners has led to the adoption of for medical attendance in many cases. Mere compliance with formal rules and evasion of censure will in the end take the place of real efficiency. So far from admitting that such a system leads to a saving of expense, we are convinced that the ultimate effect must be a great increase of it. With respect to the rich, even if the consequences of neglected disease among the poor do not reach them, they are certain to feel the effect of a deterioration of character and talent in the medical profession. The bait of a false and mischievous economy may delude persons for a time. But when the profession is degraded—when men can find it no encouragement for honour and ability—when the worst elements in it rise to the top, and human life is laid at the mercy of those base arts of quackery and puffing, to which necessity will require a resort for success, and for which the medical profession above all others afford peculiar facilities and temptations, they may lament their short-sighted views, and may begin to see the fundamental error in their opinions, which consists in applying the rule of cheapness to what necessarily is above ordinary judgment, and what may be cheap at the highest sum, and mischievously clear at the lowest. "Unrestricted competition," as the sole standard of remuneration for the medical profession, is literally that "free trade in poisons," by which the excess of a just principle is sometimes figuratively illustrated. We have been drawn into these remarks from perceiving that the physicians of a neighbouring county have, under the compulsion of the gross injustice to which they are subject, formed themselves into a kind of ribbon association, through means of which they hope to be able to regulate the relations of members of their body and boards of guardians. But though the exact form of this defensive combination may not be the best adapted to the end in view, the grievance strongly demands redress. In the resolutions adopted we find it stated that in some divisions two horses are necessary to the physician, who is still paid but £60 a year. Such a state of things is absolutely monstrous.—*Cork Examiner.*

WHOLESOME ADVICE TO APOTHECARIES.

THE following is from a Report of a joint committee of the Philadelphia County Medical Society and the Philadelphia College of Pharmacy, relative to physicians' prescriptions:

1. The apothecary should hesitate to dispense a prescription, the handwriting of which is so imperfect as to render the writer's meaning doubtful, especially if it involves agents of a poisonous or irritating character, unless he is able, from collateral circumstances, to satisfy himself of the intent of the prescriber. In such a case, he should delay the delivery of the medicine to the patient until he can see the physician, and in doing so he should avoid committing the latter, by agreeing to send the medicine when it is ready.

2. The apothecary is justified in the same means of delay if he, after deliberate consideration, believes that the physician has inadvertently made a mistake in the quantity or dose of the article or articles prescribed; always keeping in view the physician's reputation as well as his own. Every respectful application, in such cases, to a physician, should be met in good faith and with kind feeling, even though no error should prove to exist.

3. In his demeanour and language, the apothecary should cautiously avoid compromising the physician, unless it be unavoidable, in which case honesty is the best policy, and the patient or his messenger should be told that it will be necessary to have an interview with the physician previously to compounding his prescription.

4. The apothecary is not justifiable in making inquiries relative to the patient or his disease, or remarks relative to the character or properties of the medicines prescribed, that are uncalled for, or likely to convey a wrong impression through an ignorant messenger to the patient, excepting it be done in a case where he has doubts in regard to the prescription, and wishes to satisfy himself, and here he should act with great discreetness.

5. When an apothecary is asked his opinion of a physician's prescription in a manner that indicates want of faith in the prescriber, he should waive the question, unless by a direct answer he should be able to restore that confidence. When asked the nature of the ingredients, he should be guided in his answer by circumstances, avoiding to give the desired information when he believes it would be contrary to the wish of the physician, or attended with injurious consequences. In other cases he should use his own judgment.

6. Physicians being often unacquainted with practical pharmacy, pay little attention to the order in which the several articles entering into a prescription are arranged, with the view to facilitate the operations of dispensing. It hence becomes the first duty of the apothecary carefully to read the prescription, and fix the proper order in his mind. He should, at the same time, acquire the habit of considering the quantities ordered in relation to the usual doses, and also the general bearing of the prescription; and a constant resort to this practice, based on due knowledge, must inevitably detect mistakes if any have been made.

7. Apothecaries should accustom their assistants to study prescriptions in this light, and to acquire such a knowledge of the doses and therapeutical uses of medicines as shall serve to guide them in avoiding errors.

8. The apothecary, when engaged in dispensing a prescription, should, as far as possible, avoid mental preoccupation, and give his attention fully to his task. He should acquire the habit of always examining the label of the bottle before using its contents, and he should satisfy himself that he has read the prescribed quantity correctly, by referring to the prescription anew before weighing out each article. It is also a useful precaution to have bottles containing mineral or vegetable poisons distinguished by some prominent mark.

9. As the conscientious discharge of his duty should be the aim of every apothecary, seeing that on his correct action depends, in no slight degree, the usefulness of the physician, no pains should be spared to secure the efficiency of the medicines dispensed, whether they be drugs or preparations. The latter should always be prepared of full strength, and according to the formulae recognized by the United States Pharmacopœia, unless when otherwise specially ordered.

10. The apothecary should always label and number correctly all medicines dispensed by him on the prescription of a physician; he should also, invariably, transcribe on the label, in a plain legible handwriting, the name of the patient,

the date of the prescription, the directions intended for the patient, and the name or the initials of the prescriber.

11. The original prescription should always be retained by the apothecary, whose warrantee it is, in case of error on the part of the prescriber. When a copy is requested, if, as in many instances, no objection can be urged, it should be a *fac simile* in language and symbols, and not a translation.

12. In no instance is an apothecary justifiable in leaving his business in charge of boys, or incompetent assistants, or in allowing such to compound prescriptions, excepting under his immediate and careful supervision.

13. In justice to his sense of the proper limits of his vocation to the medical profession, and to his customers, the apothecary should abstain from prescribing for diseases excepting in those emergencies, which occasionally occur, demanding immediate action, or in those every-day unimportant cases, where to refuse counsel would be construed as a confession of ignorance, calculated to injure the reputation of the apothecary, and would be attended with no advantage to either physician or patient.

14. The sale of quack or secret medicines properly so called, constitutes a considerable item in the business of many apothecaries. Many of the people are favourably impressed towards that class of medicines, and naturally go to their apothecaries for them. It is this which has caused many apothecaries to keep certain of these nostrums, who are ready and willing to relinquish the traffic in them, but for the offence that a refusal to supply them to their customers would create. At present, all that the best disposed apothecary can be expected to do, is to refrain from the manufacture himself of quack and secret medicines; to abstain from recommending them, either verbally or by exhibiting show-bills, announcing them for sale, in his shop or windows, and to discourage their use when appealed to.

15. Having in view the welfare of the community and the advancement of pharmaceutical science and interest, it is all important that the offices of prescribing and compounding medicines should be kept distinct in this city and surrounding districts. All connexion with, or moneyed interest in, apothecary stores on the part of physicians, should therefore be discountenanced. With respect to the pecuniary understanding said to exist in some instances between apothecaries and physicians, we hold that no well-disposed apothecary or physician would be a party to such a contract, and consider the Code of Ethics of the College of Pharmacy and the Constitution of the Philadelphia County Medical Society as sufficiently explicit on this subject.

16. In reference to the patronage on the part of physicians of particular apothecaries, we are of the opinion, as a general rule, that graduates in pharmacy should be encouraged in preference to others of the same date of business; and whilst admitting the abstract right of the physician to send his prescription where he pleases, we think that justice should dictate the propriety of his encouraging the nearest apothecary deserving of his confidence and that of the patient.

This code of Pharmaceutical Ethics is very good, and we commend it to the candid and patient consideration of our Dublin practitioners in this line. The 4th clause conveys a gentle hint, which some who keep Consulting Doctors may obey with advantage. To pump one man's patient, with a view to elicit information tending to his transfer to another, is neither fair nor prudent. The 5th clause is suggestive also; and to it may be added a caution against exhibiting the prescriptions of one man to another, his rival in business. The 12th clause may not be palatable to gentlemen who are seldom at home, but then it may be good for the patient and practitioner, provided always that "the boy" is not a better compounder than the man. But there is little use in our dwelling on these precepts, for when those of our town, to whom they are addressed, come to read the 13th clause, they will fling them to the wind. To advise an apothecary here in Dublin not to prescribe is to advise him not to eat: yet nevertheless some do eat who do not prescribe. Bantering, however, apart, this is really a document worth perusing. The more we consider it, the more do we believe that matters medical on the other side of the Atlantic are in a sounder state than on this.

## PROFESSIONAL PROSPECTS IN "THE STATES."

We gather from this cutting that "Doctors" are as plenty at the other as this side of the Atlantic:—

Epidemic jaundice has been for three weeks past and is at present very prevalent in Selma, Alabama. We have in this pleasant little town, situated on the Alabama river, three hundred miles above Mobile, a population of about fifteen hundred inhabitants, white and black, young and old (a New England village), and we are able to number fifteen regular practitioners of medicine.—*Phil. Med. Examiner.*

Fifteen doctors for fifteen hundred people! But they will not remain long there if they are Yankees, and we hope that they will "move on" if they are from Ireland. Be that, however, as it may, "no one starves in America." Conversing with a Surgeon from the "far west," some time ago, we asked him how an Irishman was to "get on" there, and his answer was, "Why, sir, he has only to hang out his sign in the first town he comes to; the people keep moving so, that in a year or two no one will know but that he is an old practitioner."

## COST OF MEDICAL DEGREES.

THE DOCTORATE IN PARIS.—The *Union Médicale* makes the following estimate of the cost of the Degree of Doctor of Medicine in Paris:—The collegiate education requires seven years, and to obtain the two baccalaureate degrees, two years more are necessary; then the medical studies, properly speaking, will average six years; making a total of fifteen years. The seven years at college cost 1000 francs per annum, making 7000 francs; the two baccalaureates, 320 francs; the six years at medical college, 1200 francs a year, or 7200 francs. Private courses of study, 1000 francs; matriculations, examinations, and diploma fee, 1100 francs; instruments and books, 2000 francs. Making a grand total of 18,620 francs.

If we read the handbills rightly, the Bachelor's Degree in our University costs about £170; and that of Doctor, about £200, in fees alone; a considerable portion being for fees to Lecturers, not contemplated by the statutes. We are not, however, for cheap medical education. It inevitably leads to cheap doctoring and its miseries both to patient and practitioner. Cheap John's progeny, we suspect, contribute little to the comfort or respectability of our profession in Ireland.

## POOR-LAW INTELLIGENCE.

THE following will afford insight as to the actual practical working of the measure; and we beg our readers to send us local journals containing such. But let us not be mistaken, we are not for obstructing the operation of the act, or holding up to odium those charged with its execution, but for promoting its merciful objects, and strengthening the hands of those willing to carry it honestly into effect:—

Poor-law Commission Office, Dublin, Nov. 10, 1852.

SIR,—I am directed by the Commissioners for administering the Laws for Relief of the Poor in Ireland, to state for the information of the Board of Guardians of Athlone Union, that the Commissioners have received a Report from Dr. Dillon, Medical Inspector, in reference to a recent inspection made by him of the Kiltoom and Brideswell Dispensary Districts, from which it appears that no prescription sheets have been furnished for either of those districts; and in reference thereto, I am to request the guardians to furnish a supply of the form of prescription papers for the use of the medical officer of each district, with as little delay as possible.

I am also to forward herewith for the information of the guardians, a copy of a letter which the Commissioners have addressed to the Committee of Management of the Kiltoom Dispensary District.—By order of the Commissioners,

W. STANLEY, Secretary.

The Clerk, Athlone Union.

Poor-law Commission Office, Dublin, Nov. 10, 1852.

SIR,—I am directed by the Commissioners for administering

the Laws for Relief of the Poor in Ireland, to state for the information of the Committee of Management of the Kiltoom Dispensary District in Athlone Union, that the Commissioners have received a Report from Dr. Dillon, Medical Inspector, in reference to a recent inspection made by him of the Kiltoom Dispensary, from which it appears that in that district there has been but four cases of vaccination in six months, from the 20th April last; and in reference thereto, I am to call the attention of the committee to the enclosed circular of the 7th July (No. 688), a copy of which has already been forwarded to the committee; and I am to request to be informed whether printed notices have been posted in accordance therewith, and if not, to request that the proper steps may be taken for procuring and posting the notices throughout the district without delay.

Dr. Dillon also states in his report, that he found the following observations made by the medical officer in the report book on the 23rd of October:—"I am sorry to say that fever is much on the increase. I am completely out of medicine, and request your immediate attention to it. It is so distressing to be taking poor people so far to the dispensary, and no supply for them, owing entirely to the non-attendance of the managing committee."

It further implies that the committee have held but nine meetings during nine months; the first bearing date the 15th day of March, the last on the 2nd of October, when only one member was present.

In reference to this subject, I am to request the attention of the committee to the duties to be performed by them under section 9 of the Medical Charities Act, and articles 4 and 12 of the general rules. The Commissioners trust, that the members of the committee will make arrangements for holding regular meetings in accordance with the regulations for the due transaction of the business of the committee, and especially for the performance of the important duty of examining and revising the medical relief register and other books from time to time, and the procuring the necessary supplies when required.

Dr. Dillon further states, that the dispensary of this district is situated in the village of Curnaseer, townland of Cappallisheen, and fully seven miles from the village of Knoekcroghery, the residence of Dr. O'Connell, the medical officer. From this statement, the Commissioners perceive that Dr. O'Connell is residing without his dispensary district at a distance of seven miles from his dispensary, and ten miles from the extremity of his district.

Dr. O'Connell, in his replies to queries, dated 23rd Feb., in reference to his appointment as medical officer of the district, informed the Commissioners that he was living at "Hawthorn Lodge, near Lecarrow," and the Commissioners in a letter to him of the 10th April, stated that "it is desirable that the medical officer of a dispensary district should reside within the district, and in as central a part thereof in reference to the population as practicable."

It appears, however, that Dr. O'Connell has removed further from his dispensary, and out of his district altogether, and as the Commissioners cannot approve of such an arrangement, they request the committee will urge upon Dr. O'Connell the necessity of making immediate arrangements for residing within the district, and in as central a locality with regard to population as practicable. The Commissioners request to be informed as soon as Dr. O'Connell shall have taken up his residence within the district.

It further appears from Dr. Dillon's report, that on the 4th September, the managing committee passed the following resolution:—"That the members of this medical relief committee be requested to be more careful in future in giving tickets for medical relief, as in their opinion no ticket should be given to holders of stock, one cow excepted; and that in cases where tickets are cancelled by the relief committee, notice of such cancel shall be sent per relieving officer to the party giving such notice, and that Mr. Cunniffe be requested to send a copy of this resolution to each resident member of the committee."

In reference to this resolution, I am to state that although the committee of management is empowered to cancel tickets for medical relief which may have been issued to persons who may not be in their opinion proper objects for relief, they are not authorized by law to limit the discretion of individual members by regulations such as they have agreed to at their meeting of the 4th of September.

I am to call attention to the provisions of the 9th section of the Medical Charities Act, under which it is the duty of the medical officer of a dispensary district to attend or afford medical advice and medicine to any poor person resident in

the district to whom a ticket may be given as therein provided, and the Commissioners are not able to give any more precise definition of the persons who will be fit objects for receiving medical relief under the Medical Charities Act, than that afforded by the act itself. The legislature appears to have relied on the exercise of a proper discrimination on the part of those individuals who are authorized to afford medical relief by the issue of tickets, specified in section 9 of the act, and subject only to the power of the dispensary committee collectively to cancel orders or tickets given to persons who may be improper objects for such relief.

Dr. Dillon also observes that the suggestion given at his visit in June last for some necessary improvements in the dispensary, have not as yet been carried out; and in reference to this subject, I am to request, the attention of the committee to the propriety of making the improvements required in the dispensary, for which purpose application should be made to the board of guardians for the requisite authority, if they have not already done so. — By order.

W. STANLEY, Secretary.  
Thomas H. Stevens, Esq., Hon. Secretary.

### HOSPITAL SULPHATE OF QUININE.

MR. EDWARD HERRING has introduced a preparation under this name, consisting of disulphate of quinine only partially purified. In its medicinal properties it is said to differ but little from the ordinary disulphate. It has a brownish colour, and is of course not admissible as a substitute for disulphate of quinine in general dispensing, but it has been tried in hospitals and dispensaries, and by some medical men who dispense their own medicines. The preparation is recommended on account of its economy. The final purification and decolorization of the salt being attended with some expense, the manufacturer is enabled to offer it in a partially purified state at a considerable reduction from the price at which it can be sold when purified in the usual way. The amount of impurity must be ascertained before its real value can be estimated. It may be a question whether the recognition of a preparation so imperfectly purified might not open the door to some abuse. — *Phar. Jour.*

This "purification" of medicines appears to us to be carried much too far for practical purposes, and has not led to such protection against adulteration as might be supposed; for the active principle extracted may be adulterated as well as the raw material; nay, it is often decomposed and rendered inert in compounding. If experience shall prove that this less expensive preparation is as effectual as the other, a very great object will be attained, for such is much wanted in hospital and dispensary practice.

### MEDICAL REFORM.

We print this day some fragments of one of the abortions in the shape of "A Bill" which annually come to birth at this season. If we see any prospect of it surviving, we may notice it hereafter, but at present no comments on it are demanded.

### CORRESPONDENCE.

#### OPERATION OF THE DISPENSARY ACT.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR.—Adverting to my letter of the 24th ult., published in your last impression, and the intention therein conveyed, on the part of the Ennis Board of Guardians, made manifest by a notice of motion to the effect by one of their body, to reduce the salaries of the dispensary medical officers of the union. And adverting also to a former letter of mine, bearing date July 12, 1852, published in the Press of that date, and having reference to the like intention by the same board, I feel the sincerest pleasure (although by no means personally concerned) in being enabled to convey the gratifying intelligence to the profession, that the said guardians not only did not succeed in the first instance, but that on the latter occasion (last week), the Commissioners would not even allow them to entertain the question at all, telling them by a letter (anticipating the day fixed for discussing the subject), "that it did not come within their province to consider

that question without previous notice from the Commissioners to that effect." I need hardly add, that said previous notice was not received, and that, therefore, the motion fell to the ground.

Now this is as it should be, and, inasmuch as I am always ready to quarrel with the Commissioners when I fancy they do not stand by our rights, I think it is but fair to give them credit for defending those rights; when, as in the present instance, they do it, and do it effectually too, especially as the Ennis Board pique themselves (since their successful quarrel with the Board of Health, in 1848) on being enabled to legislate on matters medical as they pleased. And I must confess, that hitherto they have been so successful as to have their acts quoted as precedents by the guardians of other unions, where views of economy tended to a like direction. This veto of the Commissioners, therefore, becomes doubly valuable, in not only curbing a very supercilious board in their works of destruction, but in placing on record a precedent which may prevent other boards from adopting, as was their wont, the acts of the Ennis Board, in medical affairs, as their guide. I could only wish that the Commissioners had tried, with equal success, the powers (supposed to be) vested in them by the words, "And they are hereby empowered, when they may see occasion, from time to time, to regulate the amount of salaries and allowances, payable to such officers respectively, and the time and mode of payment thereof;" the resolution of the Limerick Board of Guardians to dispute those powers to the contrary notwithstanding. But hoping "there is a good time coming," I remain, &c.

A MEMBER OF THE LATE MEDICAL CHARITIES COMMITTEE, AND COUNTY SECRETARY.

We cannot find the letter to which "A Fellow of the College" alludes in his note of Saturday. Could he have made any mistake as to its transmission?

### DRAFT BILL.

TO PRODUCE UNIFORMITY OF MEDICAL EDUCATION AND QUALIFICATION, AND FOR THE REGISTRATION OF THOSE LICENSED TO PRACTISE IN MEDICINE.

*Preamble.*—Whereas it is for the good of all Her Majesty's subjects that the knowledge of physic and surgery should be promoted, and that means should be afforded whereby those who have been examined and found skilful by competent authority may be known from ignorant and unskilful pretenders to the same knowledge: And whereas the laws now in force concerning the profession of physic and surgery require to be amended: be it enacted:

That a council shall be established, which shall be styled—"The Medical Council for England;" and that the Regius Professor of Medicine in the University of Oxford, the Regius Professor of Physic in the University of Cambridge, such one person shall be from time to time designated by the Senate of the University of London, the President of the Royal College of Physicians of England, and the President of the Royal College of Surgeons of England, shall be members of the said council in right of their several offices and appointments; and that the other members of the said council shall be five physicians to be chosen by the Royal College of Physicians of England, five surgeons to be chosen by the Royal College of Surgeons of England, and six medical practitioners, to be appointed by one of Her Majesty's principal Secretaries of State; each of the said appointments to be made within three months after the passing of this act; and the powers and duties vested in the said council by this act, may be exercised and executed by any six members thereof.

That there shall be paid to the members of the said several councils, such reasonable expenses incurred by the said members in performance of their duties under this act, not exceeding three guineas for each attendance, and also such reasonable allowance for mileage, as shall from time to time be allowed by the said several councils.

The said councils shall, as soon as may be after they shall have been appointed as hereinbefore provided,

meet at the following places: That is to say, the council for England at the building of the Royal College of Physicians in London, the council for Scotland at the building of the Royal College of Physicians at Edinburgh, and the council for Ireland at the building of the King's and Queen's College of Physicians in Ireland.

That each of the said councils shall, within three months after their first meeting, appoint such fit and proper persons, not being members of the said councils, as the said councils may severally choose to form an examining board for the purpose of carrying into effect the provisions of this act; and every member of such examining board shall be paid such yearly salary as the council by whom he shall have been appointed shall think fit, and shall hold office for such period as the said council shall determine.

The registrar of each of the said councils shall, within thirty days after his appointment, and shall from time to time, till the first day of February, one thousand eight hundred and fifty-four, proceed to register, in books to be kept for that purpose, on payment of a fee of five shillings, the name and place of abode, together with a description of the testimonials of every physician, surgeon, and apothecary who shall apply to be registered, and who, prior to the first day of November, one thousand eight hundred and fifty-three, shall have taken a degree in medicine in any English, Irish, or Scotch university, or who shall state his place of abode and apply to be registered, and shall produce his diploma, certificate, or licence, or shall produce a duly attested certificate, or such other proof as shall be satisfactory to the said registrar, of his having obtained a diploma, certificate, or licence to practise as a physician, surgeon, or apothecary, dated prior to the said first day of November, one thousand eight hundred and fifty-three, and granted by any English, Irish, or Scotch college or hall, or any corporation, sole or aggregate, in England, Ireland, or Scotland, legally entitled to grant the same at the time of the passing of this act: and also to every person who shall apply for the same, and who was actually practising medicine in England and Wales prior to the first day of August, one thousand eight hundred and fifteen, and who shall sign a declaration according to the form in Schedule A, to this act annexed, and also to every surgeon and assistant-surgeon of the army and navy who shall apply for the same, and whose warrant of appointment bears date prior to the said first day of August, one thousand eight hundred and fifteen, and to every person who shall have been registered as aforesaid, the said registrar shall give a certificate according to the form in Schedule C, to this act annexed, and which certificate shall be in force till the first day of February, one thousand eight hundred and fifty-four, and no longer.

Each of the said councils shall meet at least once in every three months for the despatch of business; and every person not being registered under the provisions of the next preceding section of this act, or not being a graduate in medicine, or a licentiate in medicine, of one of the Universities of Oxford and Cambridge, who intends to practise medicine after the first day of February, one thousand eight hundred and fifty-four, shall present himself before the council for the country in which he intends to practise; and if such council shall consider the person so presenting himself to be properly qualified as herein after is mentioned, they shall direct their registrar to grant to such person a licence according to the form in Schedule B, to this act annexed, on payment of a fee of five pounds; and every person to whom such licence shall have been granted as aforesaid, shall be entitled to assume the name and title of a Licentiate in Medicine.

Every person who may present himself before any of the said councils for the purpose of obtaining a licence in medicine, shall produce proofs to the said council that he has attained the age of twenty-one years, and shall also produce such testimonials as shall be satisfactory to the said council, that he has passed at least four years in some university or medical school approved of by the said council, unless he shall have been a pupil to a registered medical practitioner for at least two years, in which case he shall

have passed at least three years in such university or medical school; and that he has attended such courses of dissection, such clinical and other lectures, and such hospital practice, and has passed such several examinations before the examining board appointed by the said council, as the said council shall from time to time appoint.

Once in every three years each of the said councils shall depute three of their members to form a medical congress, for the purpose of fixing an uniform curriculum of study, in accordance with the next preceding section of this act, to be gone through by all candidates for licences to be granted by the said councils respectively; and such medical congress shall meet in London at such place and time as the council for England shall determine; the first medical congress to be held as soon as may be after the election of the said several councils.

Every person who shall be registered and shall possess a certificate in force, according to the provisions of this act, shall be entitled to practise medicine throughout that part of the united kingdom for which his certificate was issued; and every person who shall be registered in one part of the united kingdom may transfer his name to the registrar of any other part of the united kingdom in which he may be about to practise, on production to the registrar of the last-named part of the united kingdom of his licence and certificate for the current year; and the registrar shall thereupon grant to such person transferring his name a certificate, which shall remain in force till the first day of February then next ensuing.

All persons who shall be registered and possess certificates according to the provisions of this act, shall be entitled to demand and recover in any court of law, with full costs of suit, reasonable charges for medical aid, advice, visits, and medicine, rendered or supplied by them to their patients, without any other licence than such registry and certificates.

No person shall be entitled to recover any charge in any court of law for any medical advice, attendance, or for the performance of any operation, or for any medicine prescribed, administered, or supplied by him, unless he shall prove upon the trial either that he is in possession of a certificate in force, according to the provisions of this act, or that he was legally practising in the capacity in which he claims such charge at the time when the debt was incurred.

After the first day of February, one thousand eight hundred and fifty-four, no person who does not possess a certificate in force, according to the provisions of this act, shall be capable of holding any appointment in any part of the united kingdom, in the capacity of a physician, surgeon, apothecary, or other medical officer, in any hospital, infirmary, dispensary, lunatic or other asylum, lying-in hospital, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse, or poorhouse, parish union, or other public establishment, body, or institution; or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age.

If any person shall, after the first day of February, one thousand eight hundred and fifty-four, act or practise as a physician, surgeon, apothecary, or licentiate in medicine in any part of the united kingdom, without being duly registered according to the provisions of this act, and without having a certificate as aforesaid in force at the time of his so practising or acting as a physician, surgeon, apothecary, or licentiate in medicine, he shall, on conviction before any magistrate having jurisdiction in the county, city, or place where the offence was committed, forfeit and pay a sum not exceeding five pounds, nor less than forty shillings, for every such offence, to be recoverable within six months next after the commission of the said offence.

If three registered practitioners shall at any time, complain to the council of any college, or other governing body, that a person, who had obtained his licence, diploma, or qualification from such college or body, had been conducting himself in a manner calculated to bring scandal and odium on the profession, by publishing indecent advertisements or pamphlets, or immoral or obscene prints or books, or had been guilty of any other disgraceful and unprofes-

sional behaviour, or of any irregular practice, the said council, or other governing body aforesaid, are hereby empowered to cite the person accused before them, first giving him due notice, and a full statement of the charges against him; whereupon the said council, or other body, having heard the defendant, and on being satisfied that the charges have been proved, or, in default of his appearance, having decided that the charges have been proved, they are hereby required to erase the name of such person from the books or rolls of the said college, or other institution as the case may be, and shall transmit forthwith to the registrar of that part of the kingdom to which such college or other institution belongs, an official report of their decision, authenticated by the seal of such college; and the said registrar shall thereupon strike out the name of the offending party from the register in his custody, and it shall ever afterwards be excluded from every register to be kept under the provisions of this act, unless the council or other governing body by whom the name was first erased, shall readmit it into the books or rolls of such college or other institution. Provided always that the name of no person who may be possessed of a licence granted by a medical council according to the provisions of this act, shall be erased from the register, unless the registrar receive from such medical council an official decision to that effect, authenticated by their seal.

Every unregistered person who shall wilfully and falsely pretend to be, or take or use the name or title of a physician, doctor, bachelor of medicine, surgeon, or apothecary, or any name, title, addition, or description, implying that he is registered under this act, or that he is recognized by law as a physician, or surgeon, or apothecary, or a practitioner in medicine, shall, on being convicted of every such offence, before any magistrate having jurisdiction therein, pay a sum not exceeding twenty pounds, nor less than five.

Each of the said examining boards, or any members or member thereof, shall be empowered to attend with the candidates for licences in the public hospitals, or other public institutions, containing sick and diseased persons, and also in any workhouse, with the view of ascertaining the practical knowledge of such candidates in the science of medicine.

If any registered medical practitioner shall be convicted in England or Ireland of any felony, or in Scotland of any crime or offence inferring infamy, or the punishment of death or transportation, or if it shall be found by the judgment of any competent court, that any such medical practitioner shall have procured a certificate under this act by any fraud or false pretence, or that any such medical practitioner has wilfully and knowingly given any false statement, evidence, or certificate in any case in which by law the evidence or certificate of a physician, surgeon, or apothecary is required, the registrar of each of the councils, on the production before him of an office copy or extract of the conviction or judgment of the court, duly certified under the hand of the proper officer of the court, or other proof thereof, shall cause the name of such medical practitioner to be erased from the register; and every person who shall have been so erased after such conviction, or judgment as aforesaid, shall thereby forfeit and lose all the privileges of a registered medical practitioner provided by this act.

#### STRENGTH OF BATTLE'S LIQUOR OPII SEDATIVUS.

The question in the Journal for this month, "What is the true strength of Battle's solution of opium?" induced me to institute some experiments with a view of ascertaining its actual strength, and also of furnishing a means whereby the strength of other secret preparations of opium (not professing to be solutions of its salts) might be estimated. The results show the real strength of Battle's solution of opium to be the same, or very nearly the same, as that of tinctura opii, P.L., and further, that in estimating the strength of liquid preparations of opium in comparison with powdered opium, it is necessary to take into account the insoluble portion of the latter, which amounts to about one-third of its weight.—*Mr. Wilkinson of Manchester in Phar. Jour.*

M. W. HANLON, M.B.

**G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.**

*Superior Dissecting Instruments well worth the inspection of the Student.*

#### THE COMPOUNDING DEPARTMENT AT G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

**BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.**

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

*Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.*

#### SHIRTS CUT BY MACHINERY.

WEBB AND CO.'S

New System of Shirt-cutting by Machinery enables them to produce really First-class Shirts at prices lower than they have ever yet been offered.

Their Eglinton Shirts, at 2s. 6d., 3s. 6d., and 4s. 6d. each, are accurately Cut, elegant in Design, and perfectly sound in Fabric.

A large assortment of Fancy Veined Full-dress Shirts always on hand.

**THE TAILORING AND GENERAL OUTFITTING WAREHOUSES** are now most extensively supplied with every description of WINTER CLOTHING.

**THE READY-MADE DEPARTMENT** contains an immense variety of Top Coats, Travelling Coats, Wrapper Coats, Pilot and Frieze Pea Coats, at 15s., 17s. 6d., and 20s. each, which, for Workmanship and Solid Value, are not and cannot be surpassed.

WEBB AND CO.,

10, 11, and 12, CORN-MARKET.

**SURGICAL SOCIETY OF IRELAND.**

The Meetings of the Society, for the Session 1852-53, will take place at the Royal College of Surgeons on the under-mentioned Evenings, at Half-past Eight o'clock precisely:—

1852—Saturday, 20th November.

Saturday, 4th December.

Saturday, 18th December.

1853—Saturday, 15th January.

Saturday, 29th January.

Saturday, 12th February.

Saturday, 26th February.

Saturday, 12th March.

Saturday, 26th March.

Saturday, 9th April.

Saturday, 23rd April.

Members who intend to read papers before the Society are requested to inform the Secretaries of their intention a few days previously.

When the Contributor of a paper wishes that the Secretaries should read it to the Society, he will please to forward it to them some days before the Meeting.

CHARLES BENSON, M.D. } Secretaries.  
O'BRYEN BELLINGHAM, M.D. }

**THE MIDLAND RETREAT,**

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY.)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System.

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

**TO SURGEONS, DISPENSING CHEMISTS, ETC.**

SULPHATE of QUININE, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, cap-suled, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor.

Chemical Works, Trinity-street, Southwark, London.  
October 23, 1852.

**DR. BELLINGHAM ON ANEURISM.**

Lately published, 12mo, price 4s.,

**OBSERVATIONS ON ANEURISM AND ITS TREATMENT BY COMPRESSION.**

By O'B. BELLINGHAM, F.R.C.S.I.,

One of the Surgeons of St. Vincent's Hospital.

"In our opinion, he has conferred a signal benefit upon the art of surgery by his improvement of the mode of employing pressure, and upon the science by his ingenious and philosophic exposition of its operation."—*Medico-Chirurgical Review*.

"Dr. Bellingham has ably advocated the cause of compression as a highly useful and successful mode of treating numerous cases of external aneurism."—*Lancet*.

"Dr. Bellingham's little work is well worthy of attentive perusal, and we feel a confident hope that henceforth another formidable operation (as ligature of the femoral vessel even under favourable circumstances unquestionably is) may in a great majority of instances be avoided."—*American Journal of the Medical Sciences*.

"The very excellent and practical essay lately published by Dr. Bellingham, to which we would refer our readers, as containing a most masterly account of the treatment of aneurism by compression."—*British and Foreign Medical Review*.

"I conceive that for a just exposition of the principles on which that mode of treatment should be conducted, as well as for some valuable improvements in the mode of procedure itself, the surgical profession is mainly indebted to you."—*Sir Philip Crampton's Letter to the Author*.

### MISCELLANEOUS CASES AND OBSERVATIONS IN THE PRACTICE OF MEDICINE.

By J. KIRBY, LL.D.,  
Ex-Professor of the Practice of Physic in the Royal College of Surgeons, &c. &c.

#### RAPID CURE OF A VERY SEVERE FORM OF SCIATICA.

THE Rev. Mr. F. called on me a fortnight since, having come from Liverpool to consult me about a sciatic affection which he suffered from for three months, and by which he was nearly crippled. His attack was at the left side, and it was particularly keen at that part, to which he was stooped down. The pain was very great in the fold of the groin, the anterior part of the thigh, around the tuber ischii, but especially behind it, whence it followed the course of the nerve to the ankle and foot. There was also much uneasiness all over the left hip and loin. He was quite lame. The limb was wasted, and it seemed shorter than the other.

In the day time he was tolerably free from distress, so that he could go limpingly about; but when evening came, nothing could exceed his agony, which continued all night, not much mitigated by seventy drops of laudanum, which was his evening dose. His bowels were right, he ate sparingly, and took next to no stimulant.

Having had my advice while a resident in Ireland, and always successfully, in many anomalous illnesses, which I, however, believed to be of a gouty nature, he resolved he would consult me in the present instance. I prescribed as follows:—

℞ Tinct. aconiti, ʒi.  
Vini colchici, ʒiv.  
Mist. camph. unc. decem.  
Syrup. croci unc. Ft. mistura.

He was to take thirty drops of Battley's solution each night, and two tablespoonfuls of the mixture three times a night, to dine sparingly, and to have one glass of wine afterwards.

In six days his son called to say he was much better, but that the medicine made him giddy and confused his mind in the day time. I now desired he should have half

the quantity of the mixture, and continue to take it at that rate until he would see me, which would be in five days.

Mr. F. now came to town, and visited me. He had very little uneasiness, and I make no doubt it disappeared under the use of a stimulant liniment.

℞ Liniment. camph. co. ʒiv.  
" saponis, ʒiv.  
Sp. terebinth. ʒiv.  
Tinct. aconiti, ʒii. M. ft. liniment.  
℞ Ung. antim. tart. ʒi.  
Ol. palma unc. ft. ung.

Mr. F. at his second visit complained that his urine was a little painful on being passed. I ordered him pills of sed. opii and soap, with the following draught, to be taken only if he was restless:—

℞ Liq. opii sed. ʒi.  
Syrup. rheados, ʒi.  
Aquæ unc. M. ft. haustus.

About eight days from the last visit, the Rev. Mr. F. called on me to report himself a new and recovered man. He had no occasion for the night draught, and he put aside all other medicine, with the exception of the last pills I prescribed, which, for the benefit they yielded, he begged I would allow him to continue for a fortnight longer, when he hoped to see me and take leave.

#### TUMOUR OF THE BREAST.

Miss G., aged 19, whose sister has a strumous tumour of her neck, and whose other sister I attended for a very large cerycal gland, which was of strumous character, and yielded to iodine treatment, consulted me for a swelling, the size of a large almond, in the mammary lymphatic gland at the axillary side of the nipple. It was smooth, moveable, but a little hard, and not at all painful. It originated in a blow given to her a year since, and of late it has not increased in bulk.

Observations.—This tumour requires attention, and it will perhaps disappear by appropriate treatment, which will regulate the catamenia, by alteratives, by exercise in the open air, a regulated diet, and sea-bathing, and the sea-side, whither she immediately retired. In four months she was well.

## GENERAL IRRITABILITY OF THE BREAST.

Mrs. A., who is married, and has many children, and who always enjoyed excellent health, and has menstruated regularly, consulted me on account of fulness, heat, and soreness of the breast generally, but without any trace of a topical tumour. She was much alarmed, and thought of nothing but a cancer.

She has had of late much cause for anxiety of mind, and considers herself very bilious in consequence. She is also very dyspeptic, as I know by a long experience of her manner of living and thoughtful and sedentary habits.

I merely ordered her small doses of blue pill at night and a mild bitter aperient to be continued for a week, at the expiration of which time she has lost the heat, uneasiness, and soreness of her bosom.

## A PIECE OF BONE IN THE TRACHEA.

Mr. D. called on me on September 16th, in a state of great alarm. For a few days he had some cough, and the sputa were tinged with blood. He feels in good health in every other way. The cough commenced suddenly, awakening him by its great severity and disturbance from his sleep. It appeared to commence about the bifurcation of the trachea, and disappeared again on his coughing up the piece of bone which he showed me.

Questioning him on the subject of diseases of his palate or nose, he answered in the negative; but he added he had two teeth drawn the day before he was seized with the cough. Looking into the mouth, there was the remains of the hæmorrhage in the gum, showing the point from which the piece of bone was detached, and which was a portion of decayed molar process. In fact, the piece escaped in sleep into the trachea, and the irritation then caused the severe cough, which succeeded in getting rid of the bone.

## POST-MORTEM EXAMINATION OF DR. —'S CHILD, ABOUT THREE YEARS OLD, THREE HOURS AFTER DEATH: WITH A HISTORY OF THE CASE, AND SUGGESTIONS.

Abdomen: Peritoneum of parietes healthy. On the small intestines, glutinous to the feel, where a preternatural degree of vascularity existed, which seemed, however, to belong more to the substance of the intestine than to its membrane. Stomach, membranes, and viscera pale. Intestinal canal free from fæces. Small intestines in parts contracted, and fleshy to the feel. Mucous membrane in patches displayed a slight blush. Gall-bladder empty. Liver healthy in structure, but had a marbled appearance on its surface. Thorax; Mediastinum, pericardium, and heart free from every sign which indicates inflammatory action. Heart contracted: the vessels on its surface, however, contained so much blood as to give it the appearance of being injected, but not minutely, with about a dessertspoonful of liquor. Pericardium: Lungs pale anteriorly; a deep livid colour posteriorly, firm, yet crepitated on being handled. Pleura pulmonalis felt unctuous, and as if coated by a layer of lymph, which, scraping with the edge of the knife, could gather into mass. The absorbents: Left lung visible to admiration. The interior structure of the lung was red, and it cut as if its capillary system was overloaded. Heart, disproportionally large, weighty, and pale. Bones felt firm to the saw, but were of nearly an equal thickness throughout. Dura mater easily detached. Arachnoid lining displayed in patches a delicate vermilion blush, which was most remarkable. Spheroidal depressions: Slight serous effusion external to cerebral arachnoid tumour. Serous effusion in parts seemed to separate the arachnoid and pia mater. Anterior and middle lobes healthy. Post lobes displayed considerable vascularity both of membranes and cineritious substance. Right lateral ventricle contained about a dessertspoonful of sanguineous fluid, without any increase of vascularity of its lining membrane. Left

ventricle less fluid. About two tablespoonfuls of reddish serum lay around the pons varoli and medulla oblongata. Brain unusually firm, particularly internally and towards its base.

The subject of this pathological memoir was a healthy child until attacked by measles, which appeared very fully on the extremities on Sunday, the 6th of March, accompanied by considerable fever. Between Sunday and Wednesday, the chest was so much engaged, and the respiration so hurried, as to induce the father, who was a medical man, to apply six leeches below the clavicles. By these and calomel and James's powder, the patient's symptoms were for some time relieved: however, the child raved so much during Wednesday night, as to alarm the father, who, a few days previous, had lost his youngest child, who died with what he called well-marked symptoms of hydrocephalus, which succeeded the eruptive stage of measles. Thursday, the delirium continued, and on Friday I was called to see the child. Mr. — told me he sometimes was furious, and violently tore at those who attempted to move him. These paroxysms recurred only at intervals. Some moments he knew every one about him, at others he seemed to sleep, but frequently started, and sat up screaming, when his repose was thought the soundest. At the period of my first visit he was dozing, lying on his back, with his arms thrown out over the pillow, and motionless. The eyelids were glued together by a copious secretion of mucus, and the effort to separate them without moistening the parts did not for some time disturb him. Even then he did not awaken, but whined, and again relapsed into his former state of somnolency. When fully roused, he could put out his tongue when desired, and appeared attracted by my watch, which he followed with a regular motion of his eyes, even though directed towards the window. The pupils exhibited nothing symptomatic of morbid sensibility or torpor. After being awake a few minutes, he again relapsed into drowsiness; pulse frequent, small, hard; abdomen soft; skin cool; breathing easy.

Twelve leeches were applied to the temples, and a blister to the nucha: the laxatives, as given by Mr. —, to be continued. He seemed easier in the evening and more collected. During the night he grew worse, and from the delirium, the father was induced to apply the leeches again towards morning. On this day I saw him at five p.m. He was then pale, cold in the extremities, breathing with difficulty; there was no stupor, but he raved and was restless; pulse sunk and weak; he seemed greatly sunken by the leeching.

A blister was applied to the chest, both as a stimulant and to relieve the lungs, which seemed greatly engaged. He died next morning, professing his knowledge of the persons about him until within the last twenty minutes.

*Observations.*—The dissection displayed an affection principally of the serous membranes occurring in the third stage of rubeola. The serous membranes of the brain appear, however, chiefly affected. The brain, except the surface of the posterior lobes of the cerebrum, exhibited none of the marks of inflammation.

*Qu.* Does this inflammation of the brain and membranes explain the occasional delirium?

*Qu.* Will the little concern of the brain itself explain the steadiness of the eyes, the absence of strabismus, the want of coma, dilatation of the pupil, and the usual attendants upon the common forms of hydrocephalus?

(To be continued.)

**FELT AND CHAMOIS LEATHER PLASTERS.**—The Messrs. Wright and Ewing have introduced a material which is likely to be valuable to patients requiring plasters for bed-sores. It may also be useful for other purposes. It consists of a kind of felt, more soft in its texture than that which is used for hats, and is covered on one or both sides with chamois leather. The plaster is either spread on the leather or on the felt. In either case, it appears to be an application likely to prove serviceable. It may be used for removing pressure from any particular spot, by cutting a hole in the plaster at the part affected.—*Phar. Jour.*

## TRAUMATIC CATARACT—SPONTANEOUS CURE.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—On looking over some notes, I have happened upon the two following cases of traumatic cataract, which I beg leave to forward you for publication, if you consider them worthy of your space.—Yours, &c.,

HENRY THOMPSON, M.D.,  
Surgeon to the Tyrone Infirmary.

Omagh, December 1, 1852.

Andrew Truelove, aged 25, a stout healthy man, received a blow of a stone in the eye in June, 1848. The force was not sufficient to produce any external appearance of injury, but he became immediately deprived of sight. I saw him next day, and perceived a grayish opacity behind the pupil, accompanied by a trifling degree of superficial vascularity. This was removed by low diet and the application of a rag wet with cold water for a few days, and the opacity remained free from complication. He returned to his work, and I deferred the operation I thought would be required until a more convenient season.

On the fourteenth day I examined the eye again, and thought I could perceive a sensible thinning and breaking up in the centre of the opacity, so I determined to wait a little longer, and found at the end of another week that the progress of the absorption was quite manifest, there being then a clear breach in the centre of the lens, which gradually increased in size, the vision returning, *pari passu*, until nothing but a mere shred remained at the upper and inner side of the pupil, requiring artificial dilatation to render it visible, and not at all interfering with the functions of the organ, which became as perfect as possible under the circumstances, so that he could easily distinguish features and all objects presented to him before he left the gaol, in which he had been confined during the whole period.

The process of cure having commenced in the centre of the opacity, its having been so gradual and progressive, and the last remaining shred of the capsule being situated in the upper side of the pupil, are decisive proofs of this spontaneous cure of cataract having been due to absorption, and not to depression, which I believe occasionally, though very rarely, causes a similar effect.

Case 2. M. Gibbons, æt. 12, a healthy girl, was admitted into the Tyrone Infirmary on the 16th of October, 1848. The conjunctiva of the right eye was intensely vascular, and an opaque film, surrounding a slight abrasion of the surface, covered the upper and inner half of the cornea; the pupil was widely and irregularly dilated, the lens, of a bluish white colour, bulging through it and protruding the iris, which was stretched over it to such an extent that it seemed to touch the posterior surface of the cornea. On the outer side the whole eye appeared enlarged, and the zonal vascularity, denoting deep-seated inflammation, could be clearly distinguished beneath the reticular arrangement of the more superficial vessels. There was considerable tenderness on pressure, supra-orbital pain, and some, though not very marked, constitutional excitement. She could distinguish light from darkness, but had no perception of objects. Five days before she had been struck on the eye by a branch in passing through a hedge; she was immediately deprived of sight, and the eye has since been gradually assuming the above-described appearance.

She was ordered to bed, put on low diet, twelve leeches applied to temple, followed by warm fomentations, and she was ordered calomel. gr. i. ter die.

Salivation ensued on the third day, and the inflammatory appearances were found to have subsided; the opacity of the cornea was reduced to a small white speck, marking the cicatrix of the little wound at its upper and inner side, about two lines from the margin; the iris and lens retained

their former positions; all pain had disappeared, and the vision remained the same.

The calomel was discontinued, and extract of belladonna freely applied round brow and lids, and she was ordered not to open her eyes until I saw her the following day, when I came to her bedside prepared with Jacob's needle.

I had the belladonna washed off, and on raising the lid found the pupil somewhat more dilated. I then passed the needle through the opaque spot in the inner side of the cornea, and by two strokes succeeded in dividing the capsule so freely, that a milky fluid, into which the lens seemed to have been converted, escaped into the anterior chamber, and some of it followed the needle, when withdrawn, through the opening in the cornea. I then closed the eyes, and kept a single fold of old linen wet with cold water over the injured one.

Next day I examined the eye, and found the cornea full, showing that the puncture had united, and the aqueous humour sufficiently clear to admit of my perceiving that the iris had resumed its natural position, the pupil being circular, and the same size as the other. A considerable portion of the torn capsule was lying in the anterior chamber; there was some return of conjunctival vascularity.

She was directed to continue the cold water, and have a dose of senna and salts.

Next day there was some supra-orbital pain; the vascularity had reassumed its zonal arrangement, and the pupil had become slightly contracted.

Belladonna was reapplied, and the calomel repeated.

The former produced extreme dilatation of the pupil, which did not go off for three days, and the calomel was pushed on to slight tenderness of the gums, by which time all traces of inflammatory action had disappeared, and the absorption was so complete that she could distinguish objects with facility. She was then ordered improved diet, and a grain of salicine three times a day, and soon after discharged quite well.

I plead guilty to having been somewhat too curious in opening the eye the first day after the operation; had I been less impatient, the second salivation would probably have been saved. I wish to direct attention to my selection of the cicatrix of the former wound as the site of my puncture. My principal reason for doing so was, that, on the outside, the iris seemed so close to the cornea that I could not have introduced the needle in the usual place without injuring it; and the reason was, that I saved an additional cicatrix, though indeed that left by Jacob's needle can hardly be called one. It is well, too, to know that an opaque part of the cornea will heal as readily as a sound part, as the advantage of operating in such a situation must be very obvious.

These two cases present instructive examples of cataract from injury, upon which subject we find the following observations in Dr. Jacob's "Treatise on Cataract":—

"That cataract is produced by injury, no one will, I believe, deny. Puncture of the capsule by a sharp instrument, as often occurs from the accidental thrust of an awl, a fork, or a needle, or from a thorn by a slap of a bush in crossing a hedge, is immediately followed by opacity or cataract. I think I have seen the lens quite milky in ten minutes after the accident. In fact, the moment the capsule is torn open, the soft fibrous lens begins to imbibe the aqueous humour, and speedily expands, and becomes opened in its texture, at the same time losing its delicate transparency and acquiring a milky appearance. The capsule of the lens is sometimes, although very rarely, burst by a blow, without any penetrating wound of the eye, causing opacity of the lens, and its ultimate absorption. But not only is the lens rendered opaque in this way, but it is a fact, that a blow on the eye sometimes causes opacity without rupturing the capsule at all. How this happens is not very certain, but it may be caused by the detachment of the lens from its connexion within the capsule by the shock of the blow; or it may be, that the cataract in such case is a consequence of inflammation from the injury."

# A COMMENTARY ON MR. KIRBY'S CASE OF FETID ABSCESS OF THE LUNG.

By RICHARD FAUSSETT, M.D., Ballina.

My attention has been directed to a case of Fetid Abscess of the Lung, published by Mr. Kirby, in the *MEDICAL PRESS* of the 24th of November, in connexion with which my name has been introduced. It would appear that Mr. Kirby, in his laudable desire to confer on the profession the benefit of his experience, has been led to cite certain cases, and *this* amongst the rest, to serve, I presume, as beacons to the rising generation, whereby they may regulate their future practice. Now, as medicine is a science which perhaps more than any other in the present age, is sought to be advanced by the inductive philosophy or reasoning from facts, it behoves those who volunteer their aid "in building up the Temple" to take heed to the accuracy of their facts, in order that we may have the foundation sure. Under all those circumstances, it will not be deemed presumptuous, I trust, in one holding my humble position amongst the "hewers of wood and drawers of water," if I venture to glance at certain inaccuracies which by some mistake have crept into Mr. Kirby's graphic description of this interesting case of fetid abscess of the lung, and which lend a colouring to the picture that I fear is scarcely warranted by the original. From certain written records which happen to turn up from my correspondence, as well as from a tolerably distinct and vivid recollection of all the details, I now proceed to do so.

On Wednesday, the 18th of September, 1850, I was first called on to visit Mr. K., a young gentleman, residing about six miles from this town, who had been at the time about nine days ill, and was attended by Mr. Neilson of Killala, whom I met in consultation. Prior to this illness, Mr. K. had found his stomach considerably deranged, owing most probably to a large quantity of mercury which some time previously he had taken for another affection. He also occasionally complained of pain at the lower part of his chest.

While labouring under these symptoms, Mr. K. was in the habit of freely smoking cigars, and was imprudent enough to expose himself to cold (an element in the case Mr. Kirby does not deem worthy of notice) by dining out with a party of pleasure on an adjacent island, where he drank freely of rum punch, and returned home at a late hour in the night air. At the time of my visit he laboured under a severe cough, accompanied by fetid purulent expectoration streaked with blood. He had then no pain in the chest, but there was a distinct dullness on percussion over the anterior inferior portion of the right lung, indicating the seat of an abscess.\* His pulse was 80. The alvine evacuations were bilious, and neither then nor at any subsequent period of his illness did there seem to be the smallest rational grounds for supposing that "THE LIVER" was in the slightest degree affected. The tongue was almost always clean, and there was no fulness nor tenderness or pressure over the hepatic region. Having, in consultation with Mr. Neilson, ascertained some particulars of this gentleman's previous history, amongst the rest that a pseudo-syphilitic or copper-coloured leprous eruption had completely disappeared by the use of some tar pills which were ordered for him by Sir Benjamin Brodie; happening, likewise, to notice on the edges of the tongue those peculiar chaps or fissures so well described by Mathias as often appearing at the approach of winter in persons subjected to lengthened courses of mercury; and having well considered all the general features of the case, I arrived at the

conclusion that there was no evidence of a syphilitic taint existing in the constitution, and certainly no indication whatever for the further use of mercury in any form.

I am the more particular in these details, because I am well aware of the views set forth by Benjamin Bell and other authors on the subject of syphilis affecting the lungs, and it seems not at all improbable that the deterioration of the blood by syphilis should, in the secondary and tertiary forms of the disease, lead to diseases within the pulmonary tissue. Regarding the attack in the present instance, however, as one of simple inflammation terminating in abscess in a subject not otherwise healthy—i.e., delicate from previous indisposition, Mr. Neilson and myself proceeded to treat the case accordingly. A blister was applied over the seat of the abscess, not, as Mr. Kirby states, "over the pit of the stomach;" a liniment, of turpentine and acetic acid was directed to be rubbed to the upper part of the chest; pills of equal parts of ipecacuanha and extract of hyoscyamus, two grains of each (not an "emetic of ipecacuanha," as alleged by Mr. Kirby, nor yet "the decoction" of hyoscyamus—a preparation, by the way, which Mr. Kirby has had the merit of first introducing to the notice of the profession); and above all things, a diet strictly limited to farinaceous substances, fruit, vegetables, and milk, was enjoined.

By a rigid adherence to this plan of treatment for the ensuing three weeks, modified, however, in some particulars as regards the medicines—laying aside the ipecacuanha pills when we found them produce much nausea, exhibiting instead, first moderate doses of the tincture of digitalis, and subsequently prussic acid in almond emulsion, two drops three times a day, blistering over the seat of the disease, and keeping the blistered surface for some time open by means of "Brown's Cantharidine Plaster," we had the gratification, from day to day, of observing a gradual and steady amendment in all Mr. K.'s symptoms. His voice got strong; his cough became less frequent; his respiration not in the least laboured, on the contrary easy and full; his pulse about 70; his tongue clean; appetite pretty good; alvine discharges regular; not losing flesh; occasionally sitting up; taking in addition to his other medicines, cod-liver oil in clove-tea, and which, to the extent of teaspoonful doses, the stomach tolerated pretty well; when on Saturday, 12th October, Mr. Kirby arrived to see him, thought proper to reverse all the treatment without the ceremony of a consultation, and despatched a messenger to the town in which I reside with a prescription for three doses of gallic acid, each containing four grains (not "ten drops," as he himself has stated), with ten drops of tincture of hyoscyamus in mucilage of gum arabic, and pills of five grains of blue pill, and five of the compound rhubarb pill; but not a word about "acetate of lead," which it so happened I subsequently suggested, although Mr. Kirby accredits himself with having done so.

On the following day (Sunday the 13th), I was summoned to meet Mr. Kirby in consultation with Mr. Neilson, when, without noticing the discourtesy he had shown me, and which, though now I believe the oldest physician in this province, I should be sorry to exhibit towards the most junior of my professional brethren, I communicated to him freely my views of the case. Mr. Kirby spoke of giving eggs, beef-tea, and a glass or half a glass of claret, to which, as well as to his astringents and blue pill, I certainly entertained strong objections. I left the case, however, in his hands, and saw no more of Mr. Kirby or of the patient while he remained; but by all accounts during those two days he altered the regimen, and gave medicines of various kinds in tolerably quick succession, which explains somewhat at first unintelligible passage in his report—viz., "This case exhibits the dangerous mischief of heaping a variety of remedies on any patient at short intervals," and which candid admission, I suppose, Mr. Neilson and I should otherwise have appropriated to ourselves.

Mr. Kirby left on Monday evening, and on Tuesday (not "Sunday") the 15th of October, I was summoned to visit Mr. K. in the utmost haste, the messenger requesting I would not delay an instant. On my arrival,

\* Mr. Kirby describes the abscess as having been seated in "front of the lung." *Qu.* Whether in the intercostals, or between the pleura costalis and pleura pulmonalis? or does this ambiguous expression refer to the actual state of the case; viz., an abscess in the lung itself?

I found Mr. K. extremely ill indeed,\* spitting up blood copiously, writhing with most acute and distressing pain in his chest, in the right mammary region near the nipple, and with a quick sharp pulse, at 100. Having met Mr. Neilson, we had him instantly cupped to six ounces, and gave him  $\frac{1}{2}$  draught, with twenty drops of tincture of digitalis, which procured considerable relief, and in about two hours after, the pulse rising again, he was again cupped to three ounces, and the same dose of digitalis was given him at bedtime. He had a couple of motions with scybala, the pulse became soft, and the pain was relieved. I should here notice that the side of the tongue became ulcerated again, probably from the use of the blue pill, although it had previously healed by touching the small ulcers with solution of nitrate of silver. The further details of this case it is unnecessary to pursue. Mr. K. had one or two subsequent attacks of hæmorrhage, which, however, Mr. Neilson and I were able speedily to arrest. Dr. Stokes and Sir Henry Marsh were at my instance consulted about the case, and both these gentlemen gave a favourable prognosis. The latter suggested a trial of salicint† in half-grain doses, which we afterwards increased to a grain, and which, in those small quantities, was continued for some time. Mr. Kirby's much vaunted remedies all got a fair trial, and we found it necessary, in a great measure, to dispense with them all; or as the patient, I believe, himself remarked, "to throw them completely overboard." We then resumed the farinaceous regimen with milk, and fell back on the plan originally prescribed, modified of course to suit the more advanced period of the disease, and to our having done so the gentleman in question owes his recovery.

Taking a dispassionate review of all the circumstances of this case, and aided by a tolerably lengthened experience, I am irresistibly led to the following conclusions:—

In apprehended hæmorrhage from the lungs, opiates and astringents, if not given with caution, may, by confining the bowels, tend to precipitate the very evil we are desirous of guarding against. The muriate of morphia, as Christison justly remarks, is by far the best preparation of opium, and in Mr. K.'s case was substituted with advantage for Battley's sedative liquor. The extracts of cicuta and hyoscyamus, the extract and tincture of Indian hemp, as well as the tincture of digitalis, I have frequently found preferable to opiates in such cases. Gallic acid, though a powerful astringent in passive hæmaturia and menorrhagia is one of rather doubtful efficacy in pulmonary hæmorrhage; and the acetate of lead, with the addition of so much acetic acid as will prevent the formation of an oxide, is a medicine much more to be relied on.

That pulmonary abscess, like that in Mr. K.'s case, is the product of inflammation, I think there can be no question, and as "prevention is better than cure," I am unfashionable enough to believe that such abscesses might often be prevented by timely depletion.

The danger of converting a chronic case into an acute, by adopting prematurely too generous a regimen, is well exemplified in Mr. K.'s case, as seen by contrasting his state on Saturday, the 12th of October, with that in which I found him on the following Tuesday. The necessity, likewise, of adopting a prompt and energetic treatment suited to the emergency, is illustrated by the happy effects produced by cupping, by digitalis, and by relieving the bowels with suitable purgatives, such as the compound colocynt-h pill combined with hyoscyamus, which happened to be the medicine then prescribed.

Regretting exceedingly to have been obliged in the fore-

going remarks to impugn the faithfulness of Mr. Kirby's report, and wishing to pass over many trifling inaccuracies, such as his "ordering *leguminous articles of nourishment*," which, by the way, if garden peas and beans are thereby indicated, he must have found it rather difficult to procure in this country in the middle of the month of October, I cannot close without expressing my astonishment at the following passage:—"Indeed the question (*viz.*, giving mercury on the supposition of the disease being syphilitic) was once entertained by the medical persons who attended him, but both very properly yielded their judgment to Sir B. Brodie and to me who treated Mr. K." Now, Mr. Neilson, if I am not much mistaken, never entertained any such notion, and as for myself, I can only say that Mr. Kirby greatly overrates his own position, if he imagines that "his judgment" could, in the remotest degree, have influenced either my opinions or my practice. With Sir B. Brodie, during my attendance at least, no such question was ever discussed.

In conclusion, it will be seen that Mr. Kirby, in most of his details, has assumed a tone approaching somewhat to the "*Veni, vidi, vici*," of some illustrious achievement, and such as a candid survey of all the circumstances of the case will, I fear, be scarcely found to accord him.

Ballina, 30th November, 1852.

#### DEEP SUPPURATION FOLLOWING THE EXTRACTION OF A TOOTH.

(AUTHOR'S NAME LOST.)

JOHN E. of Barraford, aged 34; habits irregular, married, power-loom weaver. Had good health till Nov. 1851, when he felt pain in the left side of the face. In the latter part of February, 1852, he had the first molar tooth of the left side extracted, on the supposition that he had toothache. His face was swollen at this time. He did not get relief by the operation, but, on the contrary, his pain became much more severe; the swelling of the left side of the face increased, and the morning after he could not open his jaws.

I saw him for the first time on the 9th of March, 1852, about ten or twelve days after the operation.

*Present state.*—March 9, 1852: Face very much disfigured; unable to open his jaws; teeth perfectly locked; the left side of the face very much swollen, and extending down into Burns' triangle; the hollow between the ear and the ramus of the jaw quite obliterated; pus of a most fetid odour discharging from the inside of the mouth. I could not see as far as the position of the extracted tooth. He complains of a dull aching pain, worse at night; the swelling in the neck gives an indistinct feeling of fluctuation; his general health is pretty good, and the secretions are in a good state. I made a deep incision in the sub-maxillary space, extending to Burns' triangle, and fetid pus and sloughs came away. I also made another in the neighbourhood of the articulation of the jaw, as he complained of much pain and tension in this position: *pus alone was discharged*. Besides those incisions, I made another along the level of the jaw, along the gum, as there appeared to be a distinct collection of pus in this position; a small portion of fetid, bad-coloured pus was discharged. From these incisions he got great relief, though the swelling did not subside.

Medical treatment: Good diet; hyd. kali cum decoct. sars. comp. ter in die; with a composing draught at night. I was obliged to support him with broth and other fluids, as he could not open his mouth.

18th: Doing very well; the swellings are not so large; incisions discharging pus of a better character, but still fetid. He can merely move his jaws, but yet I cannot get in a spoon-handle. General health good. As the matter was burrowing lower in the neck, I made an incision lower down.

28th: Discharge from mouth ceased; last molar and wisdom tooth loose, but I cannot get at them; makes an attempt to open his jaws, and partly with success.

\* This state of the patient on the morning after Mr. Kirby's departure contrasts strikingly with the state in which, according to his own showing, he found him—*viz.*, "I found Mr. K. in bed, and tolerably cheerful, he had had a pretty good night, and ate his usual breakfast with appetite, and while we conversed he lay on his back, with his shoulders raised on a second pillow, and his breathing did not appear to be oppressed," &c.

† This alkaloid has since been expunged from the Dublin Pharmacopœia. Pereira recommends it in large doses.

## ON DERMOID CYSTS AND PLASTIC HETEROPTOPY IN GENERAL.

By M. LEBERT.

(Communicated to the Biological Society of Paris, August, 1852.)

In the following pages I would bring under consideration an order of cysts which it is of the greatest importance, in a physiological and pathological point of view, to understand correctly, and which are still so imperfectly known and so little investigated, as to their mode of formation and nature, that the most erroneous doctrines are extant with regard to them. In the description of them it will be necessary to enter into many of their details. I propose to give the name of *Dermoid Cysts* to those which present an internal organization analogous to skin, and which consist of either cuticle, true skin, sebaceous or sudoriparous glands, hair, fat, and occasionally teeth or bone. Under this head I will also class those ovarian cysts containing teeth and hair, which many pathologists still consider as the product of conception, which opinion, however, appears to me altogether erroneous. I may here mention, that the formation of the contents of these cysts comes under a general pathogenic law, which may be called that of plastic heterotopy.

The formula of this law is the following:—Many of the simple or compound tissues, and even the most complex organs, are capable of being generated in parts of the body where normally they do not exist. It is impossible at present to assign the limits of this law; nevertheless, I do not hesitate to apply it to cuticle, colouring matter, adipose, fibrous, fibro-serous tissue, voluntary and involuntary muscular fibre, cartilaginous and osseous structure; and amongst the more complex organs, I have found the heterotopic formation of hair, glands, and teeth. I will now enter into the consideration of their production in superficial cysts.

### First part.—Dermoid Cysts non-Ovarian.

1st. Subcutaneous dermoid cysts. I will first give the result of my investigations as to encysted subcutaneous tumours containing hair, glands, fat, cuticle, &c. The following two cases have come under my own observation:—While at Berlin in the commencement of the year 1846, M. Dieffenbach requested me one day, at his hospital visit, to remove an encysted tumour from the superior eyelid of a healthy young man, aged 24, where it had existed since birth. It had only given him inconvenience for a short time, was situated above the upper edge of the orbit, and had attained the size of a pigeon's egg; the movements of the eyelid were comparatively but little incommoded, the skin over it was moveable, while the tumour itself was but partially so, on the bone underneath.

I commenced the operation by making a semilunar incision the whole length of the tumour. Having dissected off the skin on both sides, I had the edges held apart, and then separated the cyst with a bistoury and scissors, but I found such intimate adhesions between it and the frontal periosteum, that I was obliged to leave a very little part of its base, which afterwards separated by suppuration, and did not retard the cicatrization of the wound.

The tumour was composed of a yellow fat, of the consistence of tallow, showing under the microscope granular fat without true adipose cells or fat granules. The internal surface of the cyst (complete on all sides before the operation) presented altogether a cutaneous organization; although difficult to raise the cuticle distinctly, yet it was easy to prove its existence by vertical sections, which, treated with acetic acid, showed the layers and nuclei of the epidermic cells. The covering itself was composed of a fibro-areolar tissue like the skin. All the inner surface of the cyst was covered with little fine, short, downy hairs, deeply implanted in it, whose bulbs and sheaths were very plainly visible: by the side of each hair were found two sebaceous follicles like grapes, whose excretory ducts ran into the hair. They were full of a secretion identical with the fat contained in the cyst.

Case 2. A young man, aged 24, who at the same time

also came under my observation at the clinique of M. Dieffenbach, had a little tumour, the size of a lentil, situated over the left upper eyelid, which, according to his parents account, had existed since he was six months old. It is probable it was congenital. It had increased by degrees, and at the age of 19 had attained the size of a plum, and caused a good deal of inconvenience to the patient, so that he requested an operation for its removal, which was done by making an incision along its whole length, and turning out the contents. Suppuration of the interior was kept up for five or six weeks. The wound healed, but the tumour quickly reappeared, and increased more rapidly than before, so much so that at the time of the patient's admission it was the size of a small apple. During some weeks, the tumour had become painful, and after some time inflamed, which much ran down the patient. Lancing and burning pains were felt, and had become more and more severe and permanent, the skin red, and the tumour had so rapidly increased that the eye was completely covered, and the lid could not be raised; the eye itself, however, not at all affected. The eyebrow was situated across the middle of the tumour. On the 17th February, 1846, the operation was performed in the following way:—An elliptical piece of integument was raised over the upper eyelid transversely, and the cyst dissected out. It was opened during the operation, and gave exit to a grumous substance mixed with a good deal of pus; everything went on favourably, and at the end of a month the wound healed, and the patient left cured. On examining the tumour it presented the following character:—The grumous substance was composed of a sebaceous fatty matter in little granules; the pus was healthy; the internal surface of the cyst presented all the characteristics of skin; the surface next the cavity was covered with an epithelial layer, whose superficial laminae were somewhat tough, but immediately beneath were more lately formed epithelial cells with distinct nuclei; these showed all the characters of recent epithelial cells. Beneath this layer there existed very vascular dermis. All the surface of this adventitious skin was scattered over with hairs and follicles, the former of a lightish colour, with large and well-nourished bulbs, surrounded by their sheath; two sebaceous follicles were generally accompanying them, also here and there were hairs without follicles, and follicles without hairs. The latter could be recognized with the naked eye by their pale dull colour and round lobulated form; in size they varied from that of the head of a small pin to a millet seed. When the portions of this internal membrane were rendered transparent by the action of acetic acid, it was easy to study the structure of these glands with the microscope. Their proper capsule, excretory duct, and lobulated exterior, were all manifest; they contained a yellowish fat, granular, or in little cells. I have never found hairs detached and mixed up with the fat which filled the cyst. Cases of this kind are not rare, although our surgical works say little on the subject.

Baillly mentions in the 16th volume of the "Philosophical Transactions," 1789, that Hunter removed an encysted tumour of the eyelid enclosing hairs.

Cruveilhier ("Traité d'Anatomie Pathologique," 1816,) mentions some similar cases, one by Maurice Hoffman who found in a tumour on the head and temple both attached and detached hairs. In 1810, Zetherman remarked the presence of hairs in a cyst which he removed from the superior eyelid. Dupuytren removed from a child, three years old, a tumour of the upper eyelid enclosing a substance like melted butter, and a large quantity of hairs growing from the inner surface some lines long. Petit read before the Anatomical Society a similar case.

Sir Astley Cooper has also mentioned this sort of tumour, and the French translation of his work contains the following passage:—"Sometimes these cysts enclose hair when they grow over the temple near the eyelid, or in other parts of the body covered with hair. These hairs have neither bulb nor canal, and thus of course differ from those which normally exist on the surface of the body." This opinion appears to me not quite correct, and is dis-

proved by the two cases related above, yet it is interesting to observe that Sir A. Cooper was well acquainted with the existence of subcutaneous cysts containing hair.

In the *Gazette Médicale* of 1837, there is a case by Verrot, of a hair-bearing cyst situated in the leg of a young man, *æt.* 36.

In 1838, Mr. Lawrence of London, published in the *Medical Gazette* an interesting epitome on these affections, and I am astonished that so little attention has been paid to his observations. It contains the following cases:—A young child had a small tumour near the external angle of the eye, the size of a bean, colourless, and having the skin over it moveable, and had been congenital. While extirpating it the operator found that it was situated under the orbicular muscle, and by its base was intimately adherent to the surface of the bone at the external angular process of the frontal. This cyst enclosed fat and hair of a dark colour. The author remarks that tumours of this kind are not of rare occurrence in this situation in children, that they are congenital generally, and sometimes remain stationary during life, and relates the case of a man who always had one at the external angle of the eye without being incommoded. This author then relates a singular fact, that if a portion of the cyst be left the wound will not heal. In support of this observation, he adduces the two following cases:—A young person had a tumour near the root of the nose, situated between the eyelids. It was extirpated, but never healed. Mr. Lawrence then enlarged the fistula, and found at the bottom a portion of the cyst from which some hairs were growing. It was excised, and the wound rapidly healed. The second case is similar. Here there was also a tumour near the root of the nose, but not being completely removed, a fistulous orifice remained. An incision was made, and exposed at the bottom of the fistula a portion of cyst covered with hair, which was removed, and the part healed in a short time, so that here we have three well-authenticated cases of subcutaneous hair-bearing cysts.

In the *Annales de Médecine de Prague*, a similar case is related by Dr. Ryba, and published in the *Journal de Chirurgie et d'Ophthalmologie de Walther et Ammon*. M. Ryba extirpated from the left eyelid, near the temple, of a woman, *æt.* 38, a tumour, the size of a large nut, which was deeply situated under the skin, and attached by fibro-cellular adhesions to the periosteum. The cyst when completely removed contained, besides a yellowish serum with white flakes, a quantity of detached, short hairs, like those of the eyebrow. One portion of the sac was thicker and more prominent inwards, and the hairs there were more firmly attached. The same journal relates in the 8th volume of its annals, a short account of the removal of one of these piliferous cysts, by Dr. Cramer, from the left eyelid of a countryman, *æt.* 21, where it had existed since birth.

In general, ophthalmic, more than other surgeons, have met with these cases, and there is a good description of the affection in Beer's excellent "Ophthalmological Treatise." I would have quoted above the passage from his work if he had entered into more details in support of his general description.

Beer having described the pathology of encysted tumours of eyelids and around the eye, observes that they contain a yellow pulaceous substance, mixed with many short, agglutinated, soft hairs about a line long, and that the inner surface of the cyst is all scattered over with these hairs, but they can be easily plucked out as they have no bulb.

In Cruveilhier's "Anatomie Pathologique," there is mention made of the case of a girl, *æt.* 9, who had on the middle of the nose a scab, the size of a pin's head, which, when raised, allowed the passage of a probe to the frontal sinus. By pressure, black hairs, about six lines long, could be forced out, which previously had often been discharged. Cruveilhier recommended a stimulating injection, but it is not probable (as he supposed) that it would have cured the patient. At one of the meetings of the Anatomical Society, Cruveilhier mentioned, in connexion with a communication from M. Giralde, the case of a cyst containing

hair, which he observed near the pubis. The case brought before the Anatomical Society by M. Giralde is the following:—This surgeon extirpated a tumour situated on the neck of a man, aged about 20, which was placed midway between the thyroid cartilage and the upper edge of the sternum. The patient could not recollect its first appearance. This tumour, about the size of a large nut, moveable under the skin, and fluctuating, might have been mistaken for an affection of the thyroid body, if an attentive examination had not shown that it did not follow the movements of the larynx in deglutition. An exploratory puncture gave exit to some creamy pus mixed with some white hairs, in which oil-globules were seen under the microscope. After an unsuccessful injection with tincture of iodine, M. Giralde extirpated the tumour, whose cavity contained still a little of the creamy fluid above mentioned. The interior was of a pearly white colour, smooth, except some little elevations caused by the attachment of the hairs. Two of the latter, white and much longer than the others, were attached to the deepest portion of the tumour.

To the preceding cases, I may add one of the same kind which was kindly communicated to me by Dr. Pauum of Copenhagen. A young man, aged 20, had for a long time on the outer part of the eyebrow a tumour about the size of a filbert. It was removed in autumn, 1849, by Professor Carsen, surgeon to the hospital of that city. The interior of the cyst was filled with a fatty substance and a number of fine hairs the length of those of the eyebrow; but except covering the inner surface of the cyst, these hairs were not attached; they had one extremity a little thickened, forming a bulb, and the other end terminating in a point. The fatty matter was composed of cells 1-1250th of an inch in diameter, some of which were pointed at their extremities without a distinct nucleus, and were not acted on by acetic acid. The fat presented some chemical peculiarities, of which M. Pauum did not give me the particulars. These cells were probably of an epidermoid nature, and had become of that horny consistence which renders them unaffected by acetic acid, and by enclosing the fat, their hard surface probably prevented their solution in alcohol.

One of the most remarkable circumstances in the subcutaneous production of hair is that mentioned by Lobstein, who once found hair in the black substance of a melanosis which was situated under the scalp. Unfortunately the author does not enter into any of the details of this curious fact, nor do I find any further mention of it in the description of melanosis.

Ruysh twice found cysts containing hair amongst the muscles of the neck of a cow, and not of man, the passage from Meckel (who refers to the sixth plate in place of the third) would lead one to suppose. The author compares the cyst to a humming bird's nest, and he shows in fig. 5 the circular arrangement of the hairs and the sebaceous matter in the interior. In fig. 6, he represents another cyst found in the same region, having hair arranged vertically in the interior.

The sixth plate of the same section represents a dermoid hairy mass, with a pedicle, which was expelled from the uterus of a cow.

Hunter, according to Bailly, observed subcutaneous cysts in sheep and cows, containing hair in the latter, and wool in the former. He remarks they are of frequent formation, and adds that a cutaneous structure on the interior of these cysts gives origin to these hairs.

Paget also speaks of the frequency of these productions in cattle, and it is probable that many of the preparations to which he alludes belonged to Hunter's collection.

M. Lebart, for whose opinion I entertain the greatest respect, in the course of an examination of an intracranial hairy cyst, has collected some general facts with regard to these cysts. He easily demonstrated the cuticular structure of its interior; he classes them into the superficial and deep, the latter containing more hair than the former. Their general seat is the intermuscular cellular tissue of the chest and the superficial layers of the anterior limbs, particularly below the shoulder, the different parts

of the head near the lips, nostrils, and on the back their shape is ovoid, and in size as big as a man's head.

A more elaborate work on this subject, which I regret I could not obtain, has been published by M. Guerit of Berlin. I found in the report of the Medical Society of the "Arrondissement de Gannat," the curious fact of one of these subcutaneous dermoid cysts containing hair, noticed and operated on by M. Pixier, veterinary surgeon at Saint Pourvain. This tumour, the size of the fist, was situated in the cellular tissue of a cow's neck, encysted, and perceptibly increased each year at the time of losing the hair. I hope now to have given a sufficient number of examples of the formation of glands and hair in subcutaneous cysts, and that no sensible anatomist will suppose that these circumorbital hairy cysts are the products of conception, either by inclusion or superfetation.

(To be continued.)

### ON SAVINE.

By EDWARD COPEMAN, M.D.,  
Physician to the Norwich Hospital.

(Read at a late meeting of the Norwich Pathological Society.)

THE late trial of Mr. Pascoe, a member of the medical profession, for the crime of procuring abortion, excited, as you all know, considerable interest, and, for a time, no little sympathy, on the part of his professional brethren. It has been since but too surely proved that, whatever might at first have been the opinion as to the justice of the sentence, his crime was of a deep dye, and deserved the punishment awarded. But the medical evidence on which he seemed to have been condemned is still open to criticism, and it is with the belief that practical good may result from a consideration of the principal point involved in it—viz., the propriety, or otherwise, of employing savine as a legitimate medicinal agent, that I now venture to occupy a few minutes of your time with the subject. I do not remember the exact statements made at the trial by the medical witness; but the purport of his evidence was to impress upon the jury that savine was now never given by medical practitioners for truly medical purposes; that it was a dangerous medicine; and that, when used, it was in all probability employed with some sinister intent. It therefore becomes a proper medico-legal question whether or not savine can and ought to be employed as a medical agent; for the evidence I have referred to was listened to by the judge, and probably believed by most of those who heard it; and it is important that no wrong impression on the matter should rest on the minds of judges and juries in future investigations of the kind.

Savine is an evergreen shrub, belonging to the natural family *coniferae*; and its active qualities appear to reside chiefly in an essential oil of much the same constitution as oil of turpentine. All authorities represent it as a drug possessing considerable power upon the uterine organs; but some describe it as an exceedingly useful and efficient emmenagogue, whilst others speak of it as a dangerous and poisonous medicine. "Savine and its essential oil are emmenagogues; the fresh plant is too frequently employed by the peasantry as an abortifacient, but cannot be employed for this purpose without seriously endangering the life of the mother." (Phillips' Translation, Pharm. Lond., 1851.) "It is, perhaps, the most powerful uterine stimulant of the materia medica, and is occasionally administered of amenorrhœa, though always requiring the utmost caution, lest it induce inflammatory action." (Brande's Manual of Pharmacy.) "Savine is a powerful stimulant to the uterine organs, and is employed as an emmenagogue with much benefit in amenorrhœa and chlorosis depending on torpor or deficient action of the uterine system. In consequence, however, of its poisonous properties it should be used with caution; its employment is contraindicated where there is the least tendency to irritation or inflammations of the uterus or any of the pelvic viscera." (Nelson on Medicines.) Nevin and Pereira recommend it as the most effective of all emmenagogues. I will not, however,

occupy your time by further quotations, but proceed to the relation of my own recent experience of the drug.

**Case 1.**—Amelia Woods, aged about 18, was admitted as an out-patient at the hospital on the 4th of October, 1851, for chlorosis and amenorrhœa, of a pallid unhealthy complexion, weak circulation, and inclined to be fat. I ordered her a course of steel; but as her attendance was irregular, and she seemed to derive no benefit from the treatment, I admitted her into the house on the 13th of December, and gave her for a time steel and aloetic medicines. These failing, on the 20th of January, 1852, I ordered a mixture composed of ol. sabinæ, gtts. iv.; mucil. acac., oz. j. mist. camph., oz. iij.; a fourth part twice a day. On the 24th, six drops of the oil were put into the mixture; on the 25th, eight; and on the 30th, ten; which dose—namely, five drops daily—she continued to take until the 4th of February, on which day menstruation commenced and lasted four days, in natural quantity. No uncomfortable effect from the medicine was ever complained of. She was discharged cured, and has remained well up to the present time.

**Case 2.**—Ann Ragg, a stout, plethoric-looking woman, aged 21, who had never menstruated but once, was admitted by my colleague, Mr. Norgate, March 23, 1852, for an ulcer on the leg of some standing. After a month's treatment the ulcer showed but little disposition to heal, and under the impression that it depended upon disorder of the general health, Mr. Norgate transferred the case to me.

On the 26th of April, after having tried steel and aloetic purgatives ineffectually, I prescribed ol. sabinæ, gtts. viij.; mucil. acac., oz. j.; mist. camph., oz. iij. M. cap. quartam part., bis die. On 3rd May, twelve drops were put into the mixture; on the 8th, sixteen; 10th, twenty; 15th, twenty-four; 19th, twenty-eight; 20th, thirty; 24th, thirty-four; 29th, forty—viz., ten drops twice a day. I began to despair of its doing any good, and thought of discharging her; but as her health had in no way suffered, and her leg was somewhat improved, I ordered, on the 1st of June, forty-four drops; on the 7th, forty-eight; on the 10th, fifty-two—viz., thirteen drops twice a day; and on the 11th the nurse told me the catamenia had appeared that morning. She was unwell, in a natural way, as to duration and quantity, and was soon after discharged cured, the ulcer being, I believe, also healed. This woman had the appearance of full health, cheeks full of colour, and body generally in good plight; but she suffered not the slightest ill effect, or indeed any appreciable effect, save that of the occurrence of menstruation, from the savine even in doses much larger than were stated at Mr. Pascoe's trial to be dangerous to life.

**Case 3.**—Sarah Ann Fisher, aged 15, admitted an out-patient, March 20, 1852, complaining of palpitation and general weakness, with anæmic *bruit*, and amenorrhœa. General appearance that of anæmia, with inclination to fatness, with languid circulation and costive bowels. Ordered aperients and compound steel pills. April 14th: No better. Cap. mist. ferri. c. Omitt. pill. 28th: Has complained of headache since taking the mixture. Mist. ammon. gent. Omitt. mist. ferri.

May 5th: Still no improvement, and I advised her to get an in-door recommendation, giving her, meanwhile, decoct. cinch. instead of other medicine. 22nd: She was this day received into the hospital, and menstruation took place a day or two afterwards. I gave her no medicine until June 1st, and then only some ether and gentian for her stomach, intending to wait to see what would take place when she ought next to be unwell. She suffered less from palpitation, and seemed in better health.

June 7th: She complained of uneasiness in her head and stomach, and of feeling very weak. The bowels were also very costive. R Pil. col. rhei, haust. mag. sulph. Steel pills. 25th: Much the same. R Pil. al. rhei, decoct. cinch. 28th: Pain in the back to-day, but has not yet been unwell. Hip-bath. 30th: Same state. Ordered croton oil, and mist. ferri comp. instead of pills.

July 15th: As menstruation had not yet taken place, I

began the *ol. sabinae*, in doses of a drop, twice a day. On the 17th the dose was increased to two drops, on the 19th to three, on the 20th to four, on the 22nd to five. Complaints of weakness, but less of pain in the head and stomach, and says her general health is much better. On the 25th she took six drops, bis die. On the 28th, she took seven drops. In the night she had pain in the body, and seemed not so well, but I think it was occasioned by some opening medicine taken the day before, which had acted rather powerfully. On the 31st she took eight drops twice a day, on the 2nd of August nine drops; says she feels rather sick after taking it. Not thinking, however, from the absence of pain in the stomach, that her sickness was produced by the *savine*, I continued it, giving her on the 9th twelve drops twice a day, but on the 11th she told me she felt sick after every dose, and looked more out of health, so I thought it right to discontinue the medicine for a time, and made her an out-patient, no effect upon the uterus having been obtained from the use of the *savine* in this instance.

In the hospital I have employed *savine* only in these three cases at present, but they are sufficient to prove two important facts respecting the drug—*first*, that it may be given with perfect safety in larger doses than those given in Mr. Pascoe's case;\* and *secondly*, that, as it succeeded in two out of the three cases, it *ought* to be employed in obstinate cases of amenorrhœa, especially when other more usual methods of treatment have failed.—*Prov. Jour.*

#### A CASE OF PELVIC DISTORTION, IN WHICH PREMATURE LABOUR WAS INDUCED BY THE WATER DOUCHE.

By J. P. LACY, Esq., M.R.C.S.,  
Senior Surgeon to the Newark Hospital.

L. C., aged 37, a woman of middle stature, fair complexion, phlegmatic temperament, and good general health, is the wife of an agricultural labourer; she began to menstruate at 17, and continued to do so regularly till after her marriage, at the age of 32. Has had no miscarriages, and the present is her fourth pregnancy. This woman, on account of congenital deformity of the pelvis, consisting of great projection of the promontory of the sacrum, narrowing of the pubic arch, and consequent lessening of the antero-posterior diameter, was, in her two first labours, which occurred at the full time, obliged to be delivered by means of craniotomy. The first child was a boy, the second a girl.

In her third pregnancy she was admitted into the Newark Hospital, and premature labour induced at seven and a half months, by puncturing the membranes; the presentation was an arm, the labour protracted, considerable difficulty was experienced in turning, and the child, a girl, born dead.

On the occurrence of her fourth pregnancy it was again determined to admit her into the Newark Hospital, and induce premature labour at seven and a half months, with a view of saving the life of the child. She became an in-patient on October 29, 1852, and the novel mode of operation described and advocated by Dr. Tyler Smith was pretty closely followed, except that no syphon was employed, but in its stead the distal end of the India-rubber tube was fastened to a receptacle, placed ten feet above the patient, and the other end of the tube introduced into the vagina without any enema pipe being affixed to it. When the patient was lying in bed the os uteri could with difficulty be felt high up and near the pubes; but on placing her in the bath, the alteration of position caused it to be felt much more readily. A dose of castor oil was given on admission, which operated freely, and on the 30th, at half-past nine a.m., the patient being placed in an open bath, and the uterine end of the India-rubber tube introduced into the vagina, and held opposite the os uteri, two and a half gallons of water, at 110 deg., Fah., were poured into the receptacle. As soon as this

had escaped through the tube, the same quantity of cold water was poured in, and suffered to flow against the os uteri in like manner. The patient complained of some uneasiness when the cold current first began to run. Three p.m.: The douche was repeated in the same manner as last described, but commencing with cold instead of warm water. Since the first douche, micturition has been rather frequent, but little pain has been experienced. Nine p.m.: The douche was repeated, commencing with warm water; the end of the forefinger can be introduced into the os uteri, but no pain of any consequence has occurred. 31st, half-past nine a.m.: Patient has passed a good night, and feels comfortable; the bowels have been again relieved; micturition frequent; slight pain in the back and abdomen; douche repeated, commencing with warm water. Half-past two p.m.: Some slight shivering, nausea, and giddiness have been experienced since last report; douche repeated, commencing with two and a half gallons of cold, followed by five gallons of warm water. Half-past eight p.m.: The symptoms continue pretty much as at last report; douche repeated in the usual manner and quantity, commencing with warm water. Though no perceptible change in the state of the os uteri has occurred, the patient whilst in the bath experienced increased shivering, nausea, giddiness, and pain in the back. Within an hour after the application of the douche, she had some rather severe rigors, and pains continued to increase in regularity and intensity till half-past eleven p.m. On making an examination at this time, the os was found as large as a crown-piece, the bag of membranes protruding, conical in shape, and very tense, even in the absence of pains.

November 1st, half-past one a.m.: The os is fully dilated, and the bag of membranes has almost reached the os externum; the presentation was found to be either hand or foot, but the membranes were too tense to determine which; consequently, the pains continued regular and severe, it was decided to evacuate the liquor amnii, so that in the event of its being necessary, turning might be immediately performed. On rupturing the membranes, an unusual quantity of water was discharged; one foot was found presenting, and being brought down, was secured by a noose. Pains now ceased almost entirely, and the patient obtained some sleep during the remainder of the night. At eleven a.m., she had an enema of warm water, which was repeated at two p.m.; some slight pains succeeded. At half-past two p.m., the vagina was injected with warm water. No progress being made, a scruple of powdered ergot was given at three p.m., and repeated at half-past three and four. Labour pains of considerable intensity commenced soon after the first dose, and continued to increase till half-past four, at which time a still-born male child was expelled. The head was rather large and firmly ossified, but considerably moulded by its passage through the contracted brim. The placenta followed almost immediately. At bedtime the patient took an anodyne draught, followed by a dose of castor oil in the morning. The bowels were comfortably relieved. The after-pains were slight, and the secretion of lochia and milk was natural. The recovery was rapid and uninterrupted.

Labour commenced immediately after the sixth use of the douche, and thirty-six hours after the first use of the douche. Duration of labour, eighteen hours.

The account of the foregoing case has been most correctly drawn up by Mr. Rake, the house-surgeon to the hospital. It is evident that, in this instance, though the child was lost, the chances of its being born alive were considerably greater than if the membrane had been punctured before the commencement of labour. In the present case the membranes were ruptured after the os uteri had been completely dilated by the influence of the douche. Should another case of this description come under my care, I should allow the liquor amnii to be discharged without any interference. The patient returned to her home in the country a fortnight after her delivery, and is passing in the village in which she resides a few days ago, I called and found her quite well, and in the full employment of her domestic duties.—*Lancet*, 1853.

\* Mr. Pascoe gave four drops and a half three times a day.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, DECEMBER 15, 1852.

Our miscellaneous matter in this day's number, *de omnibus rebus et quibusdam aliis*, saves us the trouble of concocting a special essay on any one particular point. If time and circumstances permitted, we should perhaps be found recording our lucubrations on the subject, which, above all others at the present moment, demands a thorough revision; that is Medical Education; but we must postpone our observations thereon for the present, merely reminding our readers of its vast importance in every point of view. We have never failed, when opportunity offered, to urge upon our readers the necessity for such aid as they can afford towards stemming the influx of uneducated persons into our profession, now so overwhelming. Formerly we had to expose the open and undisguised issue of Medical Degrees and Surgical Diplomas to unworthy candidates for them; but now we have to witness their distribution to the same class more covertly and circumspectly, but not one whit the less dishonestly. Without entering into details on the present occasion, we can with safety state that never in the history of our profession has there been penned such a chapter as might now be written on the subject of educational abuses. The art of manufacturing spurious and incompetent practitioners has been reduced to a system, and so interlaced with legitimate methods, and sanctioned by authority, that it seems absolutely impossible to counteract its influence. It is not now as heretofore with dunces and idlers when Diplomas were to be had without work or evidence of capability; on the contrary, there is work enough, and abundance of that evidence of capability which an examination affords: but then what kind of work, what evidence of fitness? Is it careful observation in the hospital, or attentive attendance in the lecture-room, or the perusal of approved books? Nothing of the kind. The student is invited, not to hear the instruction of men of experience and education, or to see the practice of competent men of character, but to hear the never-ending monotonous drawl of the grinder, *par excellence*, and to repeat the exercises of the anatomical fogleman. We should not perhaps consider it necessary to allude to this matter with a view to future amplification of our views respecting it, were it not that we see what we have never seen before, regarding it. It is not with any mere unscrupulous drudge or his machinery we quarrel; it is with the defects of our educational system which enables him to enlist auxiliaries where they least should be found. Ignorant and vulgar men must always force their way into our ranks, and a back door must always be found for them; but let us have none of the guardians of the portals of the temple consorting with the keepers of the postern, or ostentatious displays of patronizing intimacies at critical moments: and above all things, let us take care that the seeds of corruption be not sown in academic groves or collegiate courts. Income derived from certificate money and hospital dividends legitimately acquired, is like any other income; but when derived from illegitimate compacts and tacit understandings between recipients, it is very different. As we have said, however, we have not at present either time or space in our columns to enlarge upon this topic, but we propose to return to the subject.

## MEDICAL LIFE IN LONDON.

PARIS AND LONDON SURGEONS.

London, December 7, 1852.

For the advanced student or graduate in medicine, after his medical studies in Ireland, we would recommend a comparison of the schools and hospitals of Paris. Here he will find the same zeal in the clinical instruction given in the hospitals, the same good feeling and *esprit de corps* existing among pupils and surgeons that he has left at home. The Celtic mind at both sides of the straits of Dover seems to differ very little. The same appreciation of what is most true and beautiful in the science of medicine, the same fine ideal of what is due to the patient, so completely at your control, the same good intention of following out medicine strictly as a profession; while in London (we speak but the experience of all visitors in saying) medicine is a trade, the students, a general rule, not half-educated. The museums, schools, and hospitals of London are perhaps the finest in the world; anything that money can procure (and you and I know money can procure a great many things), anything that the sale of diplomas and government grants can heap up in bricks and mortar is to be met with in London. Like the ivy, however, strangling in its gnarled and tangled embrace the noble tree round which it twines, our time-honoured and æruginous colleges serve but to twine more eagerly their thick clustering and cumbrous obstructions and prejudices round the noble growth of science; jealousies and detractions in medical societies and journals doing away with that fine grave nobleness of spirit that should ever add dignity to our common calling. We may be accused of detraction ourselves, and make few friends and very many enemies, but standing on neutral ground we will take to us even one friend for the cause of suffering science. We know the Italian proverb—"Have you a hundred friends, it is not enough; have you one enemy, it is too many." Trusting, however, in the all-curative efficacy of Truth, and to the inherent vital force in medicine, at present breaking into new life despite the dead weight of quackery and colleges, we may fairly hope better things in the far skiey vista of the Future.

A comparison of several schools of medicine is of interest. If, in London, we are so multifariously practical as to keep never minding any man with one specific study, be his discoveries never so beautiful, yet the cornucopia of Continental discovery ever finds its way to our shores. At Bartholomew's and college lectures, for instance, we sit reverently at the feet of Rokitansky; our homologies are out of Oken; need we speak of the circumfluous waters of our Thames, in which analytical commissioners find such millions of unearthly things. Every one out of Ehrenberg; then Alibert, Bouchardat, Müller, Köelliker, Wagner, Humboldt, Barreswil, Bernard, Roux, Ricord, Louis, Orfila, and a half hundred others; are they not all identified, yea, one and the same, with certain specific subjects not touched in England?

Goodsir, Sharpey, Kiernan, Owen, Golding Bird, Quekett, are identified with certain discoveries, but there almost the catalogue ends; and even these without Continental discoveries would be nothing. A volume of *Medico-Chirurgical Transactions* (the 35th) has just been published, utterly without interest. And why is all this? Men like Knox, Liston, Grant, Marshall Hall, John Hunter, &c., hunted to death the moment they have an opinion of their own; anything that will interfere with the "stock on hands" of medical rubbish, among certain persons, being placed sedulously out of the market. Writers in Ireland must not be put out of countenance, or writers in Scotland or America (in all and several of which places we have reason to know the *MEDICAL PRESS* finds its way), not to speak of the *Quartier Latin* among the medico's in Paris, if any improvements in surgery or medicine are looked upon with a jealous eye: it is all in the way of trade.

The schools and hospitals of London, in full swing just at

present, are perhaps the finest in the world; the schools of Paris cannot for a moment compare with them. If our altars to the unknown gods of our English science, however, are very great, our sacrifices, we often think, are equally so. Need we speak again of the rugged miserable path trodden by our young men, scores of whom leave the College of Surgeons, its fellows, and diplomas in disgust for the bush in Australia, who look upon the College of Physicians as a great Titanic mountain, flung into the path of the honest medical man—to the quacks, a shield and protection; but under the tall shadow of which, in the weary desert of medical practice, only a few toothless old men take any comfort. Did we say at Bartholomew's our poor noble Harvey starved; or at St. George's does any thoughtful man ever enter its walls without thinking of the direful epitaph of John Hunter written in its regulation-books. Cruel mockery! Yes, is it not written in the books of the chronicles of St. George's, A.D. 1793—after they had killed him—"Resolved: That Mr. Hunter's letter to this board relating to two surgeons' pupils be preserved for future consideration."

We are in the Hotel Dieu in Paris, however, and let us turn to one of the epitaphs of their great men. What a touching theme! It is a young man of 31 years; he has written of old a beautiful essay—"Sur la Vie et la Mort"—the students bring *immortelles* and place them on his grave. It is the monument of Bichât. Desault is beside Bichât. One, says the epitaph, the restorer of surgery; the other, of medicine. "Qu'il a enrichi de plusieurs ouvrages utiles, et don't il eut aggrandie le domaine si l'impitoyable mort, ne l'eut frappe dans sa 31e année." Every French medical man loves Bichât, but such a young man in London would be sweeping the shop of some fellow of the college. Every man esteems the memory of Desault: in London, it would be with the nameless monument of Jenner.

In Aldersgate-street the Duke of Cumberland took one of the first shocks from the newly discovered Leyden-jar with the sword he fought at the Battle of Culloden—who in that part of the world does not go see the field of Culloden? But who remembers poor Mead at this time, starving in a coffee-house adjacent to Aldersgate-street. The friendship of Dryden could not keep Garth from obscurity, and in a little nook at Harrow one finds his unremembered tomb. Linaere was received in the most friendly way by the celebrated Lorenzo de Medicis—a little king in his way and time at Bologna—by Politian, another great man of the day. Linaere's Latin is the best in the profession; Erasmus thought no such scholar as Linaere existed at the period. He was the first at Oxford who read Aristotle and Galen in Greek; yet he found medicine so distracted he changed his profession. Reading the "Sermon on the Mount," he flung away the book, saying this was either not the Gospel, or we in our medical pride and obstinacy in London were not Christians. Linaere now in London would go to the wall for the man of the weekly journals that understood the bitter beer controversy; in Paris, Linaere would be esteemed like Dupuytren, Larrey, Roux, or Louis.

It may be taking a too sombre view of things to turn out their darksome shadows; the writer is perhaps quite as open to the more genial influences of what is honest and winning as the reader. We are told this week, for instance, there is a *coup d'état* at St. Thomas's Hospital, as a great piece of fun, and the appointments are open to all the profession (the fun of which is in its absurdity). There is something somewhere about a camel getting through the eye of a needle; so would it be with Linaere of this chilly income tax December who should venture to canvass for St. Thomas's. A *coup d'état* at St. Thomas's has been long wanting. Would to heaven some such men as your Graves, or Corrigan, or Stokes could be got in the precincts of St. Olaves, and the hospital would be a credit to the London school. There is one good man at the "twin cousin" of Guy's—Mr. Simon—

but he stands on the lowest rung of the ladder of promotion. If we have any particular object in these notes, it is that correct impressions should exist in many things of this kind glossed over and mistaken. Our young men are too fond of forming brilliant notions of medical practice at the English side of the Channel. Pure medicine is far finer in Ireland. Operative surgery is good in London, and specialties of various kinds in Paris. In Ireland and France the medical man ranks with the other professions; in England he rather loses by comparison with the painter and glazier. Scores of men in England get five and eight hundred a year selling silks and ribbons. It is the interest of the College of Surgeons, however, to keep a class of its members satisfied with twenty pounds a year, to act as assistants to its rich fellows. In Paris and Germany hospitals and colleges are all strictly under government *surveillance*: one branch of the profession never interferes with the other, all are useful and well paid. In London nepotism is the law of hospital appointments. Here one man is a millionaire, and another has a millstone placed on his neck in Lincoln's-inn Fields. The so-called surgeon is, in point of fact, an apothecary; the apothecary and chemist is a bone-setter and kind of midwifery or morbid surgeon: every one, even Edmund Balfour, with the motto—"Rem quocumque modo, rem."

In Paris there is much of interest in the general government, half-military management of the hospitals. Though we may not approve of the politics of the new emperor, it is only fair to say, his attention to these institutions is wonderful. The general arrangement of the patients is excellent; the modes of treatment, the peculiar shapes in which medicines are exhibited, strictly scientific. Laennec, Andral, Dupuytren, Bichât have left the imprint of their great ideas to the men who now attend in the wards—Roux, Ricord, Jobert, &c. French surgery is quite as good as English: French medicine far better.

French pantomime and gesture, so characteristic of every body in a Paris hospital, eternal ptisanes and *bouillie*, and the other insignia of the expectant treatment, we have always some lurking pleasure in noticing. One is not borne down by the thoughts of the step-mother attentions of London colleges to that crowd of poor hungry students who traverse the solemn rickety wards of King's College; or, like Dr. Calcott's "poor insect" disport their little merry hour at Guy's, smoke short pipes all the day round at Bartholomew's, or say their prayers in the monastic seclusion of the Paddington Hospital. In Paris the student leaves his school and hospital with the dignity of a professional man, and the *prestige* of the great teachers he has just left attaching to his name; in London, when "least adorned" with diplomas, the man will find himself adorned the most. All the good and wise men of the profession deplore it; none but those having an interest in the matter of diplomas, like the worthy men having a constitutional tendency to church livings, can deny it. The professional acquirements of the Paris student also are far better.

There are merely two schools in Paris, but several splendid hospitals. The *Ecole de Medicine* was founded somewhere back in the 14th century; the Dupuytren Museum, not far off in the same neighbourhood, is situated in the old refectory of some religious order. It impresses one with a tumble-down, dirty appearance, not pleasant to associate with the name of the great French surgeon. Yet this school, and the more modern dissecting-rooms at Clamart, adjoining the *Jardin des Plantes*, the classic ground of the labours of Cuvier, Jussieu, Gay-Lussac, &c., have turned out thousands of first-rate surgeons. Up to 1812 a school existed at the Hotel Dieu, no longer in existence. The effect of the dissecting-rooms, it is a curious fact, was so marked on the inmates of the hospital, that they were shut up by the government. The system of clinical instruction in Paris is most valuable; operations are magnificently performed, and the

classification of cases, especially of skin diseases, most valuable, as one walks through the wards. In Germany, in fine, we have physiology and speculation; in Paris, the expectant, do-nothing system; in London, the higgledy-piggledy do-too-much system; in Ireland, perhaps, the wise and golden mean when not abused.

We might be tempted to say something of the German schools in comparison with the French; but the lively sketch of some of the Rhenish universities in a recent number of the *Edinburgh Monthly Journal* will convey much we might wish to say. The deep science and small fees in Germany are marvellous; but the "division of labour" among the different grades of the profession is most useful, and tends in no insignificant way to the respectability of the profession. In England each man is poaching on the preserves of another. The chemist, with a bit of harlequin knowingness, changes every hour into a doctor; the surgeon is a midwife, the midwife an apothecary; the physician, like the undertaker (not half so jolly, according to *Punch*), is called in when the patient is dying. Medicine, as a science, scoffed at and disregarded. We speak of course of the popular feeling towards the profession generally, compared to the feeling in Ireland. You may have been living on "moonshine" in Ireland, as we are credibly informed, but though poor the professional exchequer may be, the position of medicine as a profession is not for a moment to be compared with the trade it seems to be in England. We seek not in this to put forward anything new, it is generally felt and lamented. In the schools at present here, nothing unusual is occurring. The St. Thomas's *coup d'état* is settled. At Guy's, with its magnificent new additions, we see little to notice; at Bartholomew's, Mr. Stanley, with his "good spirit" Mr. Pagett, has been very active of late. Mr. Lawrence, at eight o'clock in the evening, enlightening the juveniles on poisoned wounds of snakes, and now skin diseases; Mr. Skey is busy with dislocations, and hopes, in ten years time, when we have got rid of a little of our present humbug, we will all get more practical. *Synarthrosis*, *diarthrosis*, and *gomphosis*, and all such jaw-breakers, he wishes to get rid of as the income tax, which, it is frightful to think, by the way, you are now to have extended to Ireland. Dr. Todd and Dr. Budd are the persons spoken of as likely to go to St. Thomas's; but at present it is said no change will occur in the antiquities of King's College Hospital. A new "hebdomadary" is coming out; there never was so good a juncture for something new in our weekly literature; people are sick of the old journals. The dishonesty and bickerings of their various writers, the modes in which every kind of "sham" is bolstered up, and every original mind if it does not swim with the foul tide is put down, has merely nauseated all good men. Our scientific societies, under the good and able presidency of Prince Albert, are to be remodelled. We have got yellow fever, a new importation at Southampton, more than once predicted; but our colleges know as much about it as of the bite of the *cobra di capello*. When the *Times* tells us all about it, we shall all then be very disquisitional; or when the Paris school take the question up, one now second to no other in general professional interest, we shall have some little light thrown on the subject. Amongst medical journals, however, yellow fever could not stand one minute against bitter beer and Mr. Allsopp.

M. WINTERNITZ mentions in the *Zeitschrift*, &c., that he has succeeded in removing the intolerable itching in a very obstinate case of pyritids of the vulva by the following means: Fomentations three times a day to the affected parts with a solution of nitrate of silver in the proportion of three grains to the ounce. A fortnight was sufficient to accomplish the cure. The success of M. Winternitz is worth knowing, the bichloride of mercury or the chloroform, which are sometimes used, have been known to fail completely.

## APPOINTMENT OF DR. MCGEE AS MAYOR OF BELFAST.

It is not merely in compliment to Dr. McGee that we place on record his appointment as Mayor of Belfast, but also to remind our brethren elsewhere, that medical practitioners are not to be held either ineligible for such an office or disabled from discharging its duties by reason of professional avocations. We have had too much of a species of mock-modesty and affectation of professional devotion about such matters; and the sooner we pursue a different course the better. If medical men do not take a position amongst other men, they will in these go-a-head times, be found presently something less than men. When we think of him we cannot help laughing at the fussy much-ado-about-nothing doctor who would fain persuade all the world that he is so engrossed by business, that he cannot spare a moment for anything else. Dr. McGee will, we are convinced, find abundance of time to attend to his patients as well as to the duties of his office. Here is an abstract of the report of his election from the *Belfast Newsletter* :—

At the usual weekly meeting of the Town Council, held on Wednesday, the Mayor in the chair, Councillor McGee, addressing the Mayor, said—When last year you, sir, were called on to preside at this council as our chief magistrate, I had the honour of seconding your nomination, and I have this year an equally pleasing duty of nominating Dr. McGee. I can number many years since I first knew Councillor McGee as my schoolfellow; I have subsequently known him as the friend and physician of our poor, in the Belfast Charitable Society, following in the footsteps of his worthy father. Of late we had all occasion to observe, with approval, his services rendered to our town as a member of the Board of Health during the fever epidemic of 1847, and as medical inspector for our union during the severe cholera visitation of 1849. In these and other instances he acted as our unpaid officer—indeed, it would be difficult to remunerate such services. Again, as a poor-law guardian I have seen him display such business habits as convince me that he will prove a not unworthy successor even to you, sir, than whom he cannot have a better example to follow. I beg leave, then, to move that Dr. William McGee be mayor of Belfast for the ensuing year.

Councillor Lepper, in seconding the nomination, said—It affords me the highest gratification to second the nomination of my friend Dr. McGee. He is a gentleman by birth, by education, by the profession to which he belongs, as well as by his standing and position in society. I need not allude to the interest he has ever taken in all our public and charitable institutions, to the many public boards and committees of which he is an active member, and to the time—most valuable to him—which he devotes to their affairs. The mover of the resolution has informed you of the valuable and unpaid services rendered by Dr. McGee during the year of the cholera; but, as a guardian of the union, I beg to add, what perhaps few are aware of, that when, in order to mark our sense of the obligations the Belfast Union was under to Dr. McGee and his colleague Dr. Kidley, it was proposed to present them with a permanent and substantial token of our gratitude, both Dr. McGee and Dr. Kidley declined the honour, it not being consistent with their feelings to accept any reward whatsoever for any such extraordinary services to the poor. I need not refer to the position Dr. McGee occupies in his professional capacity—his being senior Vice-President of the Medical Society sufficiently attests the regard in which he is held by the profession of which he is so distinguished a member, and feeling fully assured that, from his experience of public affairs, his integrity, his impartiality, and independent character, his appointment will give as general satisfaction to all classes of the community, as it does to the members of this council, I content myself by stating that I most heartily second the motion which has been placed in my hands.

The resolution was then put from the chair, and carried unanimously.

Councillor McGee, who on rising was very warmly received, said—Mr. Mayor and gentlemen, in returning thanks, I feel that it will be wise in me to be brief. I assure you that I am proud of the honour you have conferred on me, marking, as

it does, your confidence and esteem; yet, though proud, ■ who would not be, of being considered worthy to hold the office of chief magistrate of such a town, it is an honour to which I never aspired, and my feelings are not those of un-mixed gratification, for I have before me all the anxieties and difficulties of the charge; and having, moreover, great doubt as to the compatibility of the active duties of my profession with the duties of the mayoralty, I fear lest, through any inefficiency the office of mayor should be lowered in public estimation. In selecting me to fill the office, I think you have not displayed your usual wisdom and foresight: for I look around me and see some of my seniors in years and many my superiors in intelligence; but while I on those heads give the palm to others, I yield to none in ardent desire to promote the prosperity of our town. To the members of the council individually I tender my thanks for their kindness and courtesy at all times—I may even say for their forbearance on some, and not unimportant, occasions, when I have held and expressed opinions differing from the views of the majority. The patience with which you have heard me has satisfied me that you are not disposed to restrict the legitimate freedom of debate. To you, Mr. Mayor, who have so kindly addressed me, and to my proposer and seconder, who have in the kindest spirit made an over-estimate of my claims and qualifications, my thanks are especially due. My services and exertions for the public good here and elsewhere have been referred to; ■ that point I feel that, in all I have done or endeavoured to do, I did but what it was my duty to do, believing that each, ■ as far as in him lies, should aid in benefiting our town and fellow-townsmen. Public duties cannot be performed without some personal sacrifices, and therefore I will not hesitate to devote my energies and my time, so far as I dare call it my own, to the performance of the duties of the trust. Receive, gentlemen, my sincere thanks.

#### ADDRESS to DR. LYNN OF MARKETHILL.

We are glad to have an opportunity afforded us to place ■ record this testimony to Dr. LYNN's character; and especially, because ■ refrained from noticing some trivial complaints preferred against him by one of his governors, considering them unworthy of refutation. This is our practice. We are always unwilling to enter into the defence of any of our brethren unless the case demands it, which it really did not in Dr. LYNN's case, ■ this cordial expression of sympathy and approbation proves. Some people object to our devoting a little space to such grateful tributes of affection, tendered by dispensary governors to their medical officers, considering them merely personal; but now that the relations between the parties have been so much altered, it is well to provide materials by which the past may be contrasted with the future. Whoever produces such evidence as this of the good feeling existing between the Surgeon and his employers does good service to all.

(From the Armagh Guardian.)

We have pleasure in referring our readers to the address to Dr. LYNN of Markethill, and that gentleman's reply, which will be found in our advertising columns. It must be truly gratifying to him to find those who are competent to form an opinion of his services, who have had ample opportunity of observing his professional conduct, speak in such high terms of his integrity and fidelity, while presenting him with a valuable testimonial of "sincere respect on the occasion of the closing" of the dispensary, of which he has been the medical officer for upwards of twenty years. Nothing can be more gratifying to an upright man than to acknowledge he has faithfully performed his duty, and this compliment is gracefully bestowed by the governors of the institution, who still hope for a continuation of his "valued" services.

The reply ■ couched in very affectionate terms, and we admire the moderate tone in which Dr. LYNN alludes; not to his individual triumph, but to the triumph of justice at the late inquiry at Markethill. That investigation proved that if he did not enjoy, he fully deserved "the confidence

of every governor of the institution." How truly has it been said that "good fame is like fire, when you have kindled it you may easily preserve it." The present offering is evidence that Dr. LYNN still stands high in the estimation of an extensive circle of persons of all ranks and creeds, who know the value of a faithful and humane medical officer.

(From the Northern Whig.)

On Thursday last, the 2nd inst., Dr. LYNN of Markethill ■ presented by the subscribers to the late Markethill and Mountnorris Dispensary with an address and ■ set of massive salvers on the occasion of the transfer of that institution. The address was presented by Joseph McKee, Esq., J.P. George Gray, Esq., jun., Rev. A. G. Ross, Stewart Maxwell, Esq., Sandy Small, Esq., and Mr. Samuel Byers, as ■ deputation on behalf of the subscribers. The address (which will be found in our advertising columns) is of a highly complimentary and gratifying character, and the testimonial ■ subscribed to by the Earls of Gosford and Charlemont, four rectors of the Established Church, two magistrates, two Presbyterian clergymen, two curates, two land agents, and ten private gentlemen. The plate was of a handsome and beautiful kind, and bore the following inscription:—"Presented by the Governors of the Markethill and Mountnorris Dispensary to Joseph M. LYNN Esq., M.D., in testimony of their approval of his laborious and skilful attention to the poor of that neighbourhood for the space of twenty years. 1852."

#### THE CASE OF MR. COX.

We cannot in justice refrain from inserting the following letters, which, as far as we are concerned, probably, close the case. We first noticed the matter without the slightest personal knowledge of any party concerned, or the slightest idea of handling it with any other view than that of making our readers acquainted with the practical working of the general-practitioner-system in England, which many are anxious to adopt in Ireland. How far the case before ■ affords encouragement to adopt such a course is doubtful, but it is obvious that the mere fact of an alleged mis-application of a practice should not be held decisive of its demerits. We are not advocates for entrusting the duties of a medical practitioner and pharmaceutical operator to one man; but if the less opulent or more obtuse in such matters will have it so, how can we object:—

To the Editor of the *Lancet*.

SIR—When you first attacked me, you brought forward as facts what were merely the allegation of the opposing counsel, much of which had been absolutely disproved on the trial.

Instead of acknowledging that you had been misled, which justice to me required of you, you now assert that the facts had gone the rounds of the newspapers, uncontradicted, and were repeated at the meeting of the branch of the association which lately met at Bristol. I deny the correctness of your statement.

You now endeavour to prejudice the mind of the profession against me, by asserting that I shrank from the trial by resigning. You ought to have stated what that trial was to be. You ought to have stated that it was not to be in open daylight, but one carried on in secrecy, where witnesses, whose interested feelings were opposed to me, were to be allowed to talk me down *unsworn*.

I have not shrunk from *fair public investigation*. It was only necessary for me to have paid into court the money claimed of me by the plaintiff, and the public would have heard nothing of the case *Bourn v. Cox*. But because I would not shrink from public investigation, I allowed the case to go to trial.

Again, it would have been easy for me to have resigned immediately I heard that it was likely that the case would be brought before the Provincial Medical Association, and I heard this soon after the trial; but because I would not

shrink from investigation I continued a member. Nay, I myself virtually mooted the question, by forwarding to each member a pamphlet containing an account of the case, and also by reading a paper on the scientific question.

When the subject was brought before the branch at a special meeting, I might again have avoided the public inquiry by taking advantage of a law of the society, but I waived my right to do this, and courted investigation, so long as it was fair and public. This law would have given me two months at least, during which time I could have resigned, but that would have been shrinking from inquiry, and that I would not do. When it was proposed to refer the subject to the council, even those opposed to me declared it unnecessary, and claimed that the meeting could and should then decide.

Nobody at that meeting intimated that the council would take the course subsequently proposed to them; and when I was officially informed of the course contemplated, I determined that I would not submit to it. I had not shrunk from public investigation—I had courted it; but I would not allow malevolence under the protection of secrecy to utter its falsehoods against me unchecked, by the fear of the danger which publicity involves.

I now tax you with being an advocate, whilst you claim to be an impartial judge: and in the attack you have allowed yourself to make another medical journal which it seems has defended me, you render it evident, that even selfish motives may have prompted you to this attack on me.

You may talk loudly of defending the profession, but such conduct as yours really lowers it in the public estimation.—I am, sir, your obedient servant.

W. A. Cox.

*To the Editor of the Provincial Medical and Surgical Journal.*

SIR,—The letter in the last *Journal*, of the five medical gentlemen who gave evidence against me, necessitates my laying before your readers the testimony they gave. I need not notice the evidence of Mr. Topp, for on this occasion he dissociates himself from the other medical gentlemen. I, therefore, will commence with the second medical witness, Mr. C. A. Harries, who says:—"He never during his practice saw the two diseases described coexisting in the same patient;" "no practitioner in France, England, or elsewhere, ever heard of such a case;" "had never seen the two diseases coexist, and the best authors agree in the opinion that they do not." "Sir Astley Cooper was out of fashion now. Sir Astley Cooper and Mr. Hunter would have said 'aye' to this question. Mr. Lawrence, and the writers of the present day, would say 'nay.'" Mr. Skeate follows Mr. Harries, and to the fairness and proper feeling with which he gave his evidence I take this and every other opportunity of testifying. He, however, says (I doubt not with perfect good faith):—"I never saw a case in which the two diseases coexisted together." Mr. Field is then called, and says:—"He could not have walked without limping, if he had had a bubo; he did not walk limping; never saw a case with the symptoms described coexisting; it is possible the two diseases may be cotemporaneous, but (with great emphasis) in all my experience I never witnessed it." Mr. Bartrum was then called; and he is reported to have agreed with the other medical witnesses. But he also said what I repeated before him at the Bristol meeting, and what he did not then attempt to dispute, "If a patient had phymosis, a bougie could not be passed." On being asked why, he said:—"Because there would be inflammation of the glans penis." And then being asked if inflammation of the glans existed in natural phymosis, he said:—"No, that is a natural state of things." Mr. E. L. Bagshawe winds up the medical evidence by saying:—"I do not believe that the whole of this diseases mentioned existed at the same time." Upon the medical evidence, the judge charges the jury "that not less than six medical gentlemen of experience and repute had been called to give an opinion on that bill. As one witness after another was called, they all agreed that they did not believe that such a case ever existed;" "they did not believe that the diseases which were specified upon the face of the bill ever could coexist in the same patient."

This, then, was the medical evidence given by these witnesses. And I ask,—Is it worthy of members of a profession called honourable, to shift the responsibility of it, by the quibble that they did not assert that syphilis and gonorrhoea could not possibly coexist? Was not this the legitimate deduction from their evidence, and the conclusion which an unprofessional auditory must draw therefrom. Of this there can be no doubt. They appear to have been led astray by

Mr. Topp, who boldly asserted that gonorrhoea gave an immunity from syphilis, and in their zeal for the professional honour, they gave evidence which I challenged them at the Bristol meeting, before professional men, to maintain. I again challenge them to do so, or to deny that they gave this evidence. Let them meet me fairly either by saying that they had been inadvertently led astray by Mr. Topp, and thus make me the only reparation now in their power for the injury they have done me; or let them come forth and say the evidence we gave we still believe to be true, and are prepared to maintain. But let them not think to escape by the miserable quibble, that they did not assert that syphilis and gonorrhoea could not possibly coexist.

These gentlemen say they went to the trial without any communication with the plaintiff. Had they no communication previous to the trial with the plaintiff's son-in-law?

They also pledge their veracity that the jury were not influenced by their opinions as to the coexistence of gonorrhoea and syphilis. But I assert, that those five gentlemen cannot themselves, on calmly reflecting on the whole evidence, given at the trial, believe the jury were uninfluenced by this opinion. Neither will any other person, viewing the whole evidence, doubt that the jury must have been strongly prejudiced by the decision against me. At present, sir, I have no more to say to these gentlemen, but shall be prepared to reply to anything they may have to advance in further justification of their evidence.—I am, sir, your obedient servant,

W. A. Cox.

#### TO CORRESPONDENTS.

OUR correspondent, "A Member of the late Medical Charities Committee and County Secretary," should send some one to our office for a note directed to him by another correspondent, or should furnish an address to which it can be forwarded. Authors of reports of cases are requested to furnish their papers finished for the printer, and never to leave anything to a private note, or mixed up with matters of business.

#### CORRESPONDENCE.

##### THE MEDICAL CHARITIES ACT.

###### TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—In the midst of the pelting of the pitiless storm, has it ever occurred to us, shipwrecked mariners on the lee-shore of Sir William Somerville's Medical Charities Act, to appeal to the good sense (if to no other faculty) of the "collective wisdom" now assembled on the floor of St. Stephen's, in the form of a respectful prayer?

Wilberforce liberated the West Indian niggers: it may fall to the lot of Whiteside to achieve some relief for their brethren of the "red and black tickets" (Forms E. 2 and 1) of this land of saints and sinners.—Yours,

County Cork, Dec. 9, 1852.

QUANTUM VALEAT.

###### TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—The enclosed envelope contains my address for your correspondent, the "County Secretary," which perhaps you would be so kind as to forward to him; and if he will do me the favour of communicating with me, I will give him the details of a system of intimidation, cajoling, and injustice which he, in his philosophy, never dreamt of. The doubts of the Commissioners as to the power the 8th section of the Act relating to salaries gives them, are truly ludicrous; particularly when, by virtue of the *very next sentence*, they assume the power of dismissing a surgeon without a trial, or without a complaint (beyond, perhaps, some *private representation*), in as off-hand and slap-dash a manner as the Prince President could have done.

Again, the 18th section, "empowering them to enter dispensaries," could not have been more freely interpreted *even* by a Garryowen boy; and on that clause "empowering them to make rules and regulations," the devil himself could not have put a looser construction. Doubts, indeed! *Credat Judeus*—straining at a gnat and swallowing a camel.—Yours truly,

A FELLOW OF THE COLLEGE.

## TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—The Kilmacthomas Union is one lately formed out of portions of the Waterford and Dungarvan Unions. It is of small extent, and has very few resident gentry: the entire private practice within its bounds would not return £200 per annum. Under the Medical Charities Act it was divided into two dispensary districts, to which Dr. Coughlan and Dr. Walker were appointed as medical officers, at salaries of £100 per annum each. The new poorhouse having been lately finished, the guardians advertised for a medical officer at £40 per annum. Dr. Coughlan, who resides near it, wrote to the guardians declining to stand as candidate for the situation at that salary, and of course there was no other applicant. The guardians, in a pet, have retaliated by an effort to reduce the dispensary salaries to £80, but I fancy will find themselves checked by the course which the Commissioners have taken with the Ennis Board.

Public boards feel themselves at liberty to take advantage of the medical profession whenever competition can be brought to bear against it, but when its members attempt to retaliate by taking advantage of its absence, they cry out loudly against them. Dr. Coughlan deserves great credit for his manly stand against a grinding board, and I trust will be successful in obtaining adequate remuneration for his services.

J. M.

## CONCEPTION BEFORE THE APPEARANCE OF THE MENSES.

By W. T. TAYLOR, M.D., Philadelphia.

THE general experience of the medical world has established it as a physiological fact, that conception cannot take place prior to the appearance of the menses. But there are instances of females becoming mothers, who have never menstruated; they, however, must have conceived just at the time when the catamenia were about to be established, which after parturition and suckling probably occurred regularly. The following case, which I have met with, seems to be an anomaly in the annals of midwifery: During the month of June, 1851, I was requested to visit Hannah B., a mulatto, who was pregnant with a illegitimate child, and was much surprised at finding my patient herself a mere child in appearance and manner. She was thirteen years old on the 3rd of the previous February, and though she had never menstruated, was, when I saw her, in the eighth month of gestation. Her general condition was plethoric; her breasts well developed, and the areola quite dark. On the 13th of August she was taken in labour, but in consequence of a prolapse of the funis umbilicalis, which could not be replaced, I delivered her of a still-born child, of the usual size, and perfectly formed. The lochia continued for a few days, and she passed through the accustomed period after delivery very favourably. It is now one year since, and her menses have not yet made their appearance, nor has there been any vicarious discharge; her health during the whole time remaining perfect. Never having read of a case of the kind, I have sent it to you for publication, should you think it of sufficient interest.—*Phil. Med. Examiner.*

## A GOOD SAMARITAN.

THE village of East Tytherly has experienced a severe visitation from a fever of the typhoid type, by which fifty or sixty individuals were laid prostrate. The resident landowner, Mr. Cooke, immediately requested Mr. Fox, the medical officer of the union, to pay the most unremitting attention to the poor sufferers, and to debit Mr. Cooke with his charges for professional attendance. He further engaged the services of a day-nurse and a night-nurse from the hospital at Southampton, to administer the medicines and other necessary relief to the invalids, and placed at their disposal an unlimited supply of wine from his own cellars, together with such a generous diet as the circumstances of each case might demand. The result has been that the malady has only proved fatal in four instances, an elderly man and three children being the victims.

## UNIVERSITY OF LONDON.

THE following Works have been selected by the Examiners for the Examination in Logic and in Moral and Intellectual Philosophy, for the Degree of DOCTOR OF MEDICINE in the Year 1853:—

*Logic.*—Bacon's *Novum Organum*, Part I.*Philosophy of the Mind.*—Cousin's *Analysis of Locke's Essay* (being the third volume of his *Cours de Philosophie*).*Moral Philosophy.*—Butler's *Analogy*, Part I. Stewart's *Outlines of Moral Philosophy*.

By order of the Senate,

R. W. ROTHMAN, Registrar.

Somerset House, December, 1852.

Price 1s., by post 1s. 6d.,

On Friday next, the 17th Instant, will be published,  
A LECTURE ON THE WORKING OF THE  
"MEDICAL CHARITIES ACT,"

pointing out its defects and the injustice done both to the Medical Profession and the Sick Poor by it as at present administered, and suggesting Remedial Measures.

By ANDREW ELLIS,

Fellow and late President of the College of Surgeons; Surgeon to the Royal Infirmary, Jervis street; Professor of Surgery in the School of the Apothecaries' Hall of Ireland, &c. &c.

Dublin: Fannin and Co.

## SHIRTS CUT BY MACHINERY.

WEBB AND CO.'S

New System of Shirt-cutting by Machinery enables them to produce really First-class Shirts at prices lower than they have ever yet been offered.

Their Eglinton Shirts,

at 2s. 6d., 3s. 6d., and 4s. 6d. each,

are accurately Cut, elegant in Design, and perfectly sound in Fabric.

A large assortment of Fancy Veined Full-dress Shirts always on hand.

THE TAILORING AND GENERAL OUTFITTING  
WAREROOMS

are now most extensively supplied with every description of  
WINTER CLOTHING.

THE READY-MADE DEPARTMENT

contains an immense variety of

Top Coats, Travelling Coats, Wrapper Coats, Pilot and  
Frieze Pea Coats,

at 15s., 17s. 6d., and 20s. each,

which, for Workmanship and Solid Value, are not and cannot  
be surpassed.

WEBB AND CO.,

10, 11, and 12, CORN-MARKET.

**AN ADDRESS FROM THE GOVERNORS OF THE LATE  
MARKETHILL AND MOUNTNORRIS DISPENSARY  
TO JOSEPH M. LYNN, ESQ., M.D.**

DEAR SIR,—Many of your old friends, subscribers to the late Markethill and Mountnorris Dispensary, were anxious to present you with some public testimony of their good will and sincere respect on the occasion of the closing or transfer of that institution. Circumstances just then intervened which induced them to defer the execution of their wishes. It would have been indelicate to come forward in such a manner while your conduct as medical officer of the dispensary was undergoing judicial scrutiny.

They had every confidence that the result would be honourable to you. They are now happy to congratulate you on the decision of the proper tribunal given in your favour after such a searching inquiry; and they hope that the town and dispensary district of Markethill may long enjoy the services of one so well known and valued there, as the kind friend and skilful physician of the poor.

We feel it our duty thus publicly to testify our sense of the unwearied, anxious, devoted care you have for twenty years bestowed upon your poor patients. You have not only conscientiously attended to their cases, according to the duty of your office, but you have felt for their troubles; you have been afflicted in their affliction. You have ever liberally ministered to their necessities from your own stores. We have seen you fearlessly discharge your duty when the stoutest might have shrunk from the manifold forms of fearful death surrounding us on every side; we have seen you smitten down almost to the grave, overwhelmed by the weight of perilous duty, in days when famine and pestilence were alike destructive.

Your worth was then proved. Who, knowing it at such a time, could ever forget it?

We cannot, and will not, forget it. We feel ourselves bound in justice and in gratitude to record our sentiments in a permanent manner, and therefore we beg your acceptance of the accompanying small token of their continued and unfading esteem from your sincere and faithful friends.

Signed on behalf of the Meeting,

JOSEPH MCKEE, J.P., Chairman.

Markethill, December 3, 1852.

**DR. LYNN'S REPLY.**

*To the Governors of the late Markethill and Mountnorris Dispensary.*

MY LORDS AND GENTLEMEN,—It is indeed truly cheering to one's heart to have the kind sympathy of sincere friends, but it did not need your flattering address, nor the valuable present of plate by which it is accompanied, to assure me of the unflinching friendship of the Governors of the late Markethill and Mountnorris Dispensary.

I shall never cease to feel the deep debt of gratitude I owe for the noble and disinterested manner in which you came forward to do me justice upon a late trying occasion, and I am most thankful to God for the result.

I reflect with pleasure on the friendship subsisting between us during the twenty years spent in your service. Some of that period was marked by famine and dire disease; but in the midst of all my arduous labours I was supported and comforted by the conviction that I enjoyed, as I conscientiously strove to deserve, the confidence of every governor of the institution.

In the reports of your dispensary, I was happy to be able, from year to year, to give honourable evidence of the efficient aid and encouragement afforded me by the Governors in the discharge of my duties, and now at the close of our official connexion I am glad to have this public opportunity of placing on record my heartfelt thanks to the many faithful friends who for so long a period cheered my heart and strengthened my hands.

I could sincerely wish that I had fully deserved your kind testimony as to my efficiency amongst the poor, and Christian sympathy for their sufferings; but I can honestly say that, while my best services were mixed with much imperfection, my earnest desire was to be useful, and no earthly consideration afforded me greater delight than to give relief to suffering humanity.

Words cannot express how highly I prize the present mark of your continued confidence and esteem; and I can only say that while I have a heart to feel, I shall not forget

the kindness of the Governors of the late Markethill and Mountnorris Dispensary.

I have the honour to be, my Lords and Gentlemen, your faithful servant,

J. M. LYNN, M.D.

[The plate consists of a massive set of salvers, manufactured by West and Co., of Dublin, and on each salver is inscribed—"This set of salvers presented by the Governors of the Markethill and Mountnorris Dispensary to Joseph M. Lynn, Esq., M.D., in testimony of their approval of his laborious and skilful attention to the poor of that neighbourhood for the space of twenty years. MDCCCLII."]

Now ready, cloth, 8vo, pp. 346, price 9s.,

**SYPHILITIC DISEASES:**

Their Pathology, Diagnosis, and Treatment, including Experimental Researches on Inoculation, as a Differential Agent in Testing the Character of these Affections.

By JOHN C. EGAN, M.D., M.R.I.A.,

Fellow and Licentiate of the Royal College of Surgeons in Ireland; Member of Council of the Surgical Society of Ireland; formerly Surgeon to the Westmorland Lock Hospital, &c. &c.

London: John Churchill, Princes-street, Soho.

Dublin: Fannin and Co., Grafton-street.

**TO SURGEONS, DISPENSARY CHEMISTS, ETC.**

SULPHATE OF QUININE, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, capuled, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.

October 23, 1852.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

**THE COMPOUNDING DEPARTMENT AT  
G. O. AND CO.'S MEDICAL ESTABLISHMENT**

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

Printed by Thomas Deery, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin.

Wednesday, December 15, 1852.

OBSERVATIONS ON THE PUSTULE MALIGNE AS IT APPEARED AT GIBRALTAR: WITH CASES.

By CHARLES TRENERRY, Esq., M.R.C.S. Eng., Assistant-Surgeon to the Civil Hospital, Gibraltar.

(Communicated by Dr. Tyler.)

ABOUT the last quarter of the year 1850, a patient was admitted into hospital, having his head, face, neck, eyelids, nose, ears, and upper part of chest greatly swollen, with little or no discolouration of skin, guttural respiration, and a loud croaking voice. His faculties were unimpaired nearly to the moment of death, which took place a few hours after admission, apparently from suffocation. No pustule was visible. He was unable clearly to account for the disease, but said that it came on during the night, whilst sleeping on board a vessel in the bay.

Such is the history of the first case that drew my attention, and which in reality I looked upon as phlegmonous erysipelas; but the little alteration of the colour of the skin, the total absence of fever, and the rapidly fatal termination, led me to believe some venomous reptile had inflicted the injury.

Other similar cases having presented themselves shortly afterwards, the nature of the disease was less equivocal, and pronounced by experienced physicians to be the pustule maligne, of a virulently contagious nature.

Boyer, in his "Traité des Malades Chirurgicales;" Vidal, "Pathologie Externe;" Rochaux, in the "Dictionnaire de Médecine," and other authors who have had considerable experience, also assert that the disease is of a contagious nature, and depends upon a specific poison or virus existing in animals in the form of carbuncles or malignant fever at particular seasons; and that it is particularly prevalent in the province of Lorraine, Franche Comté, and Bourgogne, where it frequently breaks out epidemically, and destroys large numbers of animals.

Indeed, the disease is considered so highly contagious,

that flies and other insects which have been in contact with the matter, are said to convey the infection to individuals or any animal they alight on; it is even supposed to be engendered by eating the meat or coming in contact with the blood of animals suffering from this peculiar disease: in short, such is the indestructible nature of the virus, that whatever preparation the hides or wool undergo, it cannot be impaired; such being the fact, we are greatly exposed to this dreadful malady.

On the other hand, M. Bayle, in a paper read at l'Ecole de Médecine of Paris, maintains that the disease may arise independently of contagion; and that nearly all the cases coming under his care were certain of not having been in contact with any affected animal.

The cases that have come under my observation, incline me to the same opinion, particularly as the development of the disease in the few cases that occurred in Gibraltar were attacked in the bay under such opposite circumstances, within an area of about a mile, crowded with shipping, and not more than one or two persons on board each vessel that furnished cases were affected, but nearly all those vessels had or had had hides, &c., on board; therefore, the inference might be, that they only came in contact with the particular spot, and that those who had not been near any hides or wool could have had the infectious matter conveyed through flies or other insects.

That such an opinion cannot be entertained, I think is conclusive, from the fact of none of the medical men or relatives in attendance on those affected contracted the disease, which, if so virulently contagious, would certainly have infected some of us, having frequently had our fingers unavoidably covered with blood and matter issuing from the sloughs that formed; further, I have inoculated some kittens with matter taken fresh from infected subjects without the slightest ill effects ensuing beyond that occasioned by the punctures.

I am, therefore, inclined to suspect that insects are generated at some particular period or under some peculiar condition of the animal, and lodge in the hide or wool, from whence they are apt to escape and seek a nidus in the skin

of any other animal, which in its turn becomes affected with the poison secreted, *sui generis*, of this insect.

What renders this latter hypothesis the more probable is (from information received from creditable sources), that the disease is unknown in those parts of Barbary from whence the hides and wool are exported. I am also told by a respectable merchant of this place, who receives large shipments of those articles, that he requires every hide to be unfolded and thoroughly examined before shipping them off, as they are frequently found to contain a number of small dead flies, not unlike moths, and to be perforated by small black-looking worms or maggots, particularly along the spinal portions, which are cut out with a piece of the hide, and if the holes are large or many exist, the hide is rejected.

I have requested that a few of these worms and flies should be sent me at an early opportunity, and I will take care to observe their habits and whatever transformations they may undergo, and report accordingly.

The characteristic symptoms were a slight itching on some part of the face, followed by a small pimple, having a dark depressed centre, not unlike a spurious vaccine pustule, surrounded by several almost imperceptible phlyctenæ, from whence oozed an ichorous fluid. The glands of the neck on the affected side, but more especially the parotid, became enlarged and indurated. The head, face, neck, and upper part of the thorax, were afterwards frightfully swollen and disfigured, the tumefaction having a peculiarly tense and elastic feel; the respiration was laborious and attended with a singular croaking sound; whilst the voice was of a disagreeable guttural nature.

Death took place with singular rapidity, while recoveries have been tedious, as far as the local symptoms were concerned, the constitutional disturbance seldom being severe.

The treatment consisted in an immediate and free application of the actual cautery to the affected spot, and afterwards the lotio plumbi diacetatis, sometimes a weak linimentum ammoniæ, which were sure to arrest the disorder, if applied within twenty-four hours from its appearance. The bowels were cleared out by aperients, and other symptoms, such as fever, suppuration, and sloughing, treated on general principles.

*Case 1.*—A man was admitted into the hospital with considerable tumefaction of the head, face, neck, eyelids, nose, ears, and upper part of the chest, a loud croaking voice, and guttural respiration. The only account he can give of it is, that the disease came on during the night, while sleeping in the hold of a vessel. A few hours after admission he died, apparently from suffocation. He was sensible to the moment he died. There was no pustule visible.

*Case 2.*—On October 21, 1850, Christoba Martinez, æt. 60, a tall and robust Portuguese, navigating on board a vessel laden with wool and salted bullock hides from Larachè, presented himself as an out-patient, having the left side of the neck, face, and eyelids considerably swollen. There was no perceptible pustule or mark of puncture on any part of the swelling, although he said he at first experienced pain on the left upper lid. The swelling rapidly increased to a frightful extent, involving the whole of the head, face, neck, and upper part of the thorax. Extensive suppuration and sloughs occurred on the left side of the face, attended with frequent hæmorrhage; so much so, that I was consulted as to the propriety of tying the carotid artery. Drs. Mery and Cortes attended him at his own residence until he was sufficiently recovered to attend as an out-patient.

Nov. 30th: The conjunctiva and lids of the left eye are thickened and œdematous: there is a large granulating surface with inverted edges over the left temple; an irregular scar extends down the cheek; his general health good. It was nearly four months before he recovered.

*Case 3.*—November 13, 1850, Manuel Fernandez, æt.

60, applied for admission as an out-patient, having a considerable tumefied swelling, extending about two-thirds round the throat; there is no pustule visible; his occupation is that of a fisherman; says he has not been on board any vessel having hides or wool, nor has had anything to do with these articles.

Liniment. ammoniæ.

Mist. cathartic.  $\mathfrak{z}$ iii. statim.

14th: He requested to be admitted into the hospital, and died seven hours afterwards from suffocation. He swallowed easily everything that was given to him, free from pain, fever, and thirst, and was sensible to the last moment. He was a relation of Christoba Martinez (*Case 2*).

*Case 4.*—Francisco Sapeira, æt. 48, a Spaniard, navigating on board a Portuguese vessel, laden with hides and gum from Barbary, was admitted October 18, 1850, having a distinct pustule over the left inferior orbital ridge, with considerable swelling of the left eyelids and cheek, which he attributes to having picked off a small pimple on the lower eyelid when he awoke this morning. There is no heat of skin or pain; pulse regular. Dr. Rey applied the actual cautery, and ordered the lotio plumbi diacetatis to be constantly applied. He was put into bed, and took a dose of the hospital purgative mixture.

19th: Passed a pretty good night; the swelling has not increased; a dark eschar has formed where the cautery was used; bowels freely acted on. He gradually lost all swelling of the face, and was discharged November 6th, having a tough unyielding eschar, about an inch and a half in length, and the surrounding integument adherent to the bone; there remained a slight ectropium.

*Case 5.*—November 19, 1850, Francisco Docarmen, æt. 68, a Portuguese, had been navigating on board the same vessel as Francisco Sapeira (*Case 4*), but it is a fortnight ago since he quitted the vessel, and has been sleeping on board another laden with wood. On Sunday morning, the 17th instant, whilst shaving himself, he cut a small pimple near the right commissure of the mouth, since which his face has been gradually swelling. He is cheerful and in good general health, and smiles incredulously at my representing his disorder as dangerous.

There is a very small dark spot near the right angle of the mouth, with several small vesicles around it containing a yellowish serum, some of which is oozing out; underneath, the spot is indurated. The left side of the face and neck greatly swollen. I applied the actual cautery, and directed the linimentum ammoniæ to be constantly used to the swelling; he returned home, and in the afternoon consulted another practitioner, who made a free incision into the affected spot.

20th: The patient was brought into the hospital with considerable tumefaction of head, face, neck, and upper part of chest; respiration stertorous, and features livid; he is quite insensible, and throws his hands about as if grasping at something, and in fact has all the appearance of an apoplectic seizure; life appeared to have ceased several times previous to the evening, when he died.

*Case 6.*—November 19, 1850, Jose Pedro, æt. 15, a Portuguese, states that when he awoke yesterday morning, he discovered a small pimple near the external angle of the right eye. In the evening he experienced a sharp fever, and this morning found the right side of the face, neck, and eyelids much swollen, attended with a burning sensation in the pustule. A fortnight since he was engaged on board a vessel for three days in unloading Barbary hides, but has had no communication with any other vessel or hides. I applied the actual cautery, and ordered the linimentum ammoniæ to be frequently smeared over the swelling. 20th: Says he passed a very good night, and had neither fever nor pain; swelling of the eyelids and face much subsided, but a hard circumscribed swelling over the parotid remains.

Misturæ catharticæ,  $\mathfrak{z}$ iii. statim.

Continuent. linimentum ammoniæ.

21st: Swelling of face much increased; a languid expression of countenance; pulse feeble; respiration somewhat laboured and guttural; to be admitted into hospital,

and take a tablespoonful of the following mixture every hour:

*R* Spts. ammon. aromat.  $\mathfrak{z}$ i. ; *Acet. mor.*  $\mathfrak{z}$ ss. ; *Hydrarg. chlorid.*  $\mathfrak{z}$ ss. ; *Conserv. rose.*  $\mathfrak{z}$ ss. ; *Quinquina*  $\mathfrak{z}$ ss. ; *Syrupi simplicis*,  $\mathfrak{z}$ ii. *M. Fiat.*

In the evening there was great acceleration of pulse, hurried respiration, heat of skin, and profuse diaphoresis. Omit. mist. ammon. & reapply the actual cautery, and use the lotio plumbi diacetatis.

Dec. 4th. He was discharged cured.

Case 7.—November 30, 1850, Juan Bayerler, *ætat.* 20, states that last Monday he was engaged in unloading hides, since which time he has had nothing to do with them. For the last three or four days he has had a small pimple just above the supraorbital ridge, but paid no attention to it until this morning, when he awoke and found the left side of the face and neck much swollen, which induced him to procure admission into the hospital. He suffers no pain; pulse rather weak; skin cool, with heavy and languid expression of countenance; habits of life in temperate. I applied the actual cautery to the pustule, which he bore without any apparent sensibility.

*R* Mist. ammon. aromat.  $\mathfrak{z}$ i. secunda quaque hora.  
Appl. liniment. ammon.

Dec. 1st and 2nd: Swelling has increased, with a good deal of fever. Appl. lotio plumbi diacetatis.

3rd: Swelling subsiding; delirium tremens set in during the night, and he became so violent that it was necessary to put on the strait jacket.

*R* Acetat. morphæ, gr. iii.  
Hydrarg. chlorid. gr. xxiv.

Conserv. rose, quant. suff. ut fiat pilul. xii.  
quar. sum. i. tertia quaque hora.

4th and 5th: Much improved in every respect, and was discharged cured on the 29th.

Case 8.—December 3, 1850, Juan Catania, *ætat.* 13, was standing on the wharf last Sunday afternoon, when he experienced a slight itching on the upper lid of right eye, and the following morning he discovered the lid to be swollen. At present there is a distinct spot on the lid, having all the appearance of a small-pox pustule; the lid is swollen and diaphanous; the cervical gland near the angle of the jaw is hard and swollen; he has no pain or fever; he states positively he has not touched hides or wool, nor has he been on board any vessel containing these articles. Dr. Rey and myself were at first disposed to think it an ordinary pimple, but the magnifying glass showed the characteristic pustule maligne. He refused to be cauterized, and went away.

4th: His mother brought him to the surgery; the swelling has much increased; he refuses to inhale chloroform, and struggled so violently that I could only cauterize imperfectly; he ran away from the hospital, but ultimately recovered.

Case 9.—March 2, 1851, Lorenzo Pau, *ætat.* 22, says as he awoke the day before yesterday, he perceived a small pimple on the right cheek; he has been engaged in weighing salted hides on board a vessel from Tunis. There are numerous small vesicles on the skin, where the ichor from the pustule has touched. Submaxillary gland is indurated and painful to the touch. Apply the actual cautery, and afterwards the linimentum ammoniac. He was quite cured.

Case 10.—January 12, 1852, Jose Rivero, *ætat.* 38, observed a small pimple, about ten days ago, on the upper part of his forehead while at Larachè, loading a vessel with hides, wool, dates, bird seed, &c., but he experienced no inconvenience until two days ago, when he was seized with rigors, heats, and intense pain in the head, which obliged him to keep his bed. This morning he applied at the Civil Hospital for treatment. There is an irregular dark-coloured sloughy-looking ulcer on the upper part of forehead, about the size of a sixpenny piece, rather to the left of the mesial line; its surface has a few small drops or globules of blood and ichor; an inch lower down there is a small characteristic pustule, and further back near the temple a superficial but suspicious-looking spot; the palpebræ are swollen,

particularly of the left eye, which is closed; the forehead, left side of the face, and neck, are also swollen; he complains of headache and much pain of the left side of the neck; the parotid gland does not appear to be implicated; tongue clean and moist; pulse natural. Actual cautery to the spot. Lotio plumbi diacetatis.

Mist. cathart.  $\mathfrak{z}$ ss. statim, et repetatur per mane et vespere. Passed a comfortable night; swelling lessened, and is able to open the lids, but still complains of pain in the neck; bowels acted freely. Six p.m.: The right eye-lids are much swollen and closed. Dr. Rey considered it advisable to reapply the actual cautery to the suspicious spot, as I had only touched it superficially at first, not thinking it to be the pustule maligne.

14th: Swelling of lids diminished; the seat of pustules have a prominent elevation, as if an abscess were forming; passed a very bad night, owing to the pain at the side of the neck, but was relieved by a linseed poultice; pulse weak. To have sage, wine, and broth.

15th: From this day he continued to improve, and was discharged at his own request on the 19th, but attended as an out-patient until the cauterized spots were healed by simple dressing.

Case 11.—February 21, 1852, Jose Reymundo, *ætat.* 60, is cook on board the same vessel in which Jose Rivero navigates (Case 10). He states that on rising this morning, he discovered a small pimple, with surrounding inflammation, immediately behind the angle of the jaw. The throat and upper part of throat is tumefied. The actual cautery was directly applied by Dr. Rey, and the lotio plumbi diacetatis ordered to be frequently used.

22nd: The throat is enormously swollen, and the swelling extends below the mammæ; the voice has a disagreeable croaking sound; pulse weak and intermitting; no fever. Dr. Rey reapplied the cautery, and extended it lightly round the throat, and afterwards directed linseed poultices. Bowels have been freely opened.

23rd: Swelling increasing; died soon after four p.m., but sensible to the last, and at no time complained of pain.

I removed the cauterized spot, as also the spot over the left breast; the latter proved to be a distended follicle, although at first it was not unlike the pustule maligne.

The whole of the subcutaneous cellular tissue about the throat and chest was infiltrated with serum. A further examination was not permitted, nor in fact could I obtain a post-mortem inspection in either case.

This man, it appears, was engaged the day previous to the attack in removing the mattresses from the berths, and he stated that the vessel was at present laden with sugar and iron; the hides, wool, &c., having been discharged six weeks ago.

Case 12.—April 8, 1852, Pedro Franco, *ætat.* 18, says he is employed as a labourer on board the Peninsular and Oriental Steam Navigation Company's coal hulk. Six days ago he discovered a small pimple on the left side of the neck near the ear. As it gave him little or no inconvenience, he paid no attention to it until this morning, when it had become more painful; he is positive not having been near any hides or wool, nor is he aware of any of those articles being at present in the bay.

I have since learnt there was a vessel laden with wool and hides a short distance from the hulk. The boy refused to be cauterized, and quitted the hospital. I have not heard of him since.

Case 13.—Was a healthy guard engaged in a vessel having hides on board; he was affected on the outer part of the left thigh, for which he was cauterized, and has recovered.

No notes were made of this case in consequence of my being taken ill of fever.

Dr. TYLER observed, that when he was at Gibraltar he had an opportunity of seeing three of the cases detailed by Mr. Trenerry, but he had no information to give respecting them in addition to what was contained in the interesting communication just read by the Secretary. The matter attracted the notice of the authorities at the time,

and the disease was believed to be so contagious, that an order was issued, directing the vessels, in which the cases had occurred, not to anchor near the wharf.

Dr. POWER drew attention to certain similarity of character between the pustules represented in the drawings (which accompanied the paper) and the pustule of glanders. He did not mean to establish a precise analogy between this disease and glanders, but he thought there was something in these pustules slightly characteristic of glanders.

Dr. BENSON said the subject was a very interesting one, and as an officer of the Society, he would say that the council would be much obliged if any of its members who resided in foreign countries, would forward to them papers like the present one, giving us information respecting diseases of a particular kind, not to be met with in this part of the world.

It was then moved by Professor WILLIAMS, and seconded by Professor HARGRAVE, Vice-President of the College: "That the thanks of the Society be given to Mr. Trenerry for his highly interesting communication."

#### MEDICAL SOCIETY OF LONDON.

Dr. DE MERIC showed to the Society the saccharine capsules of copaiba and cubebs, prepared by M. Jozeau, under the name of Copahine-Mége, and as this was neither a secret nor a patented remedy, he was induced to try it in his practice. He stated that he had found them very efficient in the treatment of gonorrhœa, as the mouth did not perceive the taste of the copaiba, and the stomach did not revolt against the drug. Dr. De Méric observed that his patients took the capsules without repugnance, and never complained of any gastric disturbance. He was sure that many of the fellows would find this kind of sugar plums very convenient in private practice, as they could be carried in the waistcoat pocket, and taken at leisure.

Mr. CHIPPENDALE wished to know whether the capsules were sold at a high price? He asked the question because he might be inclined to use them in his dispensary.

Dr. DE MERIC was not prepared to give the information required, as he had confined himself to the pharmaceutical bearing of the matter. But he might venture to say that M. Jozeau would probably charge hospitals and dispensaries a very low price. He thought, at the same time, that the capsules were more calculated for private than public practice.

The PRESIDENT inquired the actual amount of copaiba and cubebs in each capsule?

Dr. DE MERIC could not bring to mind the exact quantity; but we have since been informed that it is sixteen grains of prepared copaiba and about two grains of cubebs for each capsule.

#### SCIRRHUS OF THE UTERUS COMPLICATED WITH PREGNANCY; FUNIS PRESENTATION; DELIVERY.

Mr. I. BROWN read the following case:—Mrs. W—, aged 35, an out-patient of St. Mary's Hospital, was under my care from May to July with scirrhus of the os and cervix uteri. The catamenia had ceased for several weeks, but there was a good deal of offensive serous discharge. Her health became so seriously injured, that she was unable to continue her attendance as an out-patient, and I lost sight of her until November 18th, when I was requested by Mr. Hammond, one of the district accoucheurs of the Maternity, to visit her. I found that she had been seized with symptoms of labour the previous day, that the waters had escaped, and that the funis had descended six or eight inches through the os externum; but the thickened edges of the uterus seemed quite unyielding, and the labour made little or no progress. The patient became excessively exhausted, requiring ammonia, brandy, and strong beef-tea. I suggested that they should wait and see if the os dilated a little more, and if it did that delivery should be attempted by turning. Turning was accomplished the following day by Mr. Bullock, resident-surgeon to St. Mary's Hospital, and Mr. Hammond, after considerable difficulty. The fœtus was one of seven months, and

had been dead some five or six days. The patient remained in a very exhausted state after her delivery, and when Mr. Brown last saw her, was evidently fast sinking.

In answer to questions, Mr. Brown could not say how long the disease had existed, but he supposed for some time. About half the os was involved in the ulceration.

Dr. ROUTH recollected the case of a woman in Vienna, in whom three-fourths of the os were involved in the ulceration. The woman was four days in labour, and died four or five days after delivery. The delivery was effected not through the os, but on one side of it. The woman died of peritonitis.

Dr. BARNES said that the practical question in this case was, as to the propriety of effecting premature delivery to avoid the passage of a large body through the diseased os. Would such a proceeding give the patient a chance of recovery? He thought that the cases of Dr. Rowland had proved the contrary, and that as death would result whenever delivery took place, life of course would be prolonged by allowing the woman to go the full time.

#### ON THE PATHOLOGY AND TREATMENT OF SANGUINEOUS PELVIC CYSTS.

Dr. TILT read a paper on a variety of pelvic tumours, on which the French pathologists have during the last year thrown great light, the cyst being in such cases formed by a considerable quantity of blood effused in the pelvic portion of the peritoneum, or externally to the peritoneum, so as to constitute extra-peritoneal or intra-peritoneal cysts. Dr. Tilt first related several cases from his own practice, from that of Dr. Bell of Glasgow, and from that of Dr. H. Bennet; by which it appeared that the disease was preceded by menstrual irregularities, and that its origin generally coincided with the suppression or the non-appearance of the catamenia; after which ensued hypogastric swelling, then local pelvic peritonitis, on the subsidence of which a globular tumour was found to fill, more or less, the pelvis, interfering with the passage of both fœces and urine. Dr. Tilt then elucidated the pathology of the previous cases by several others which had terminated fatally in the Paris hospitals, and where the post-mortem examinations were exhibited to the Société de Chirurgie of Paris. The causes of extra-peritoneal sanguineous cysts were extremely obscure. In a case related in "Guy's Hospital Reports," the effusion of blood was caused by the rupture of an aneurismal sac. In another, occurring in the practice of the celebrated Mangolin, it was caused by the rupture of varicose sub-peritoneal veins. Light had been thrown on the causes of the intra-peritoneal variety by the post-mortem appearance of a patient under the care of Denonvilliers, of the Hôpital St. Marguerite, in Paris. The blood was found to have come from several small ovarian cavities, some of which still contained blood-clots; and in discussing the case, Lenoir, Nelaton, and other surgeons of eminence, admitted that in this and similar cases the pelvic tumour was formed by an ovarian hæmorrhage taking place during the process of ovulation. Dr. Tilt admitted the explanation, and gave it strength by reminding the Society that during the process of ovulation the ovaries greatly increased in size; that in the normal state the blood-clot taking the place of the ovum was about the size of a cherry; that microscopical observers had sometimes found the capillary vessels much enlarged and broken in the vicinity of the vesicle, and the ovarian tissue so softened that it would tear on the slightest touch, and let the blood-clot escape. Dr. Tilt gave a still surer footing to the views of the French pathologists on this point, by relating a case which had lately occurred in the Lyons Hospital, where, after flooding at three successive menstrual periods, peritonitis supervened, and on opening the body, a blood-clot of the size of a horse-bean was found protruding between the rent lips of the ovarian follicle. Having thus established the pathology of intra-peritoneal sanguineous cysts, Dr. Tilt proceeded to illustrate their history by other interesting cases which had lately occurred in the Paris hospitals. One, for instance, was mistaken by Malgaigne for a fibrous uterine tumour. He slit up the neck of the

womb to enucleate the supposed tumour, but finding his mistake, he punctured it, and gave issue to a large quantity of syrupy blood. Hæmorrhage from the wounded artery of the neck of the womb could not be controlled, and the patient died. Another case was mistaken for ovarian dropsy, others for metritis. Dr. Tilt observed that sanguineous pelvic cysts did not usually terminate fatally, but often by resolution; the lining membrane of the cyst absorbing its contents, which thus became thicker and thicker, and the tumour diminished. Sometimes, however, the contents were evacuated by rupture of the cyst per rectum or per vaginam. Dr. Tilt recommended the cysts to be left to themselves when small, and to increase absorption by moderate venesection, purgatives, and low diet; but if they attained a considerable volume, so as to interfere much with micturition and defæcation, he advised the tumour to be punctured per vaginam with a long trocar. 1st, because this plan presents a better chance of avoiding wounding the arteries; 2nd, because the trocar being left in the wound permits the gradual evacuation of the blood; 3rd, because it allows the possibility of making injections. But Dr. Tilt likewise admitted the necessity of widely opening the tumour should it contain large fibrinous clots, or if it gave rise to a fetid discharge. With regard to the frequency of the disease, Dr. Tilt did not consider it a common occurrence; and although some twenty cases had been published during the past year by eminent French surgeons or obstetric practitioners, it was so little known in England, that several talented physician-accoucheurs had assured the author that they had not met with it. Dr. Tilt, therefore, submitted, that they might have been mistaken for other complaints; for metritis and incipient pelvic abscess, when the collection of blood is small; for an ovarian tumour, when the collection is very considerable; and sometimes for pelvic abscesses, as in Dr. Bell's case, when the blood-clots were mixed with pus. He, therefore, believed that similar cases might be found recorded in English journals by those who would have time and patience to hunt for them.

Dr. DE MERIC inquired if Dr. Tilt had noticed pulsation in the tumours which he had described. In the description of one of the cases, at least, he had spoken of enlargement of the vessels, and of fibrinous deposit, &c.; might not the tumour in this instance have been aneurismal? In those cases in which recovery had taken place, which was the pathological process by which this was effected? The author had stated that he considered that hæmorrhage had occurred from the ovary in these cases at some time or other during menstruation. Now this was no doubt from excitement of the ovary. What, then, was the cause of the hæmorrhage? Had coitus anything to do with it, or any other stimulant? If we could trace the hæmorrhage to any such cause, we might warn the patient. There were no doubt, however, other circumstances connected with the menstrual period which were favourable to the development of these tumours.

Mr. BROWN regretted that so little of the paper allowed of discussion, as only one of the cases had fallen under the observation of Dr. Tilt himself. He (Mr. Brown) was inclined to think that one, if not two of the cases, was an iliac aneurism. In the case related as occurring in Dr. Tilt's own practice, no doubt the use of the trocar was proper; but he (Mr. Brown) did not think it would be so in the other cases. He did not agree with Dr. Tilt that these tumours were likely to be mistaken for uterine enlargements, as the uterus could be distinctly felt on examination; but he had seen instances in which they had been mistaken for ovarian tumours. In one case he recollected a sanguineous swelling near to the uterus, which burst into the rectum, and had been mistaken for an ovarian tumour. When the nature of the tumour could be determined by the history, and the mischief was localized, the plan of treatment recommended in the paper was proper, but it should not be resorted to when the swelling came on suddenly. Then a very different mode of proceeding was necessary. He regarded these cases generally as a kind of uterine apoplexy from obstructed menstruation, and situated in the

cellular tissue. He hoped at a future time Dr. Tilt would bring forward cases which would fall under his own observation, as some, no doubt, soon would.

Dr. S. GRIFFITH found the same difficulty as the last speaker in discussing the paper; but he would briefly relate two cases which had fallen under his own notice, and which appeared to be somewhat analogous to the one detailed by Dr. Tilt. The first was the case of a woman who had been ailing for some time, and had pain and hardness in one of the ovaries, with occasional shivering, and a mucous discharge from the vagina, unaccompanied by ulceration of the cervix uteri. She suddenly became worse, and symptoms of acute peritonitis set in without any apparent cause. Treatment was unavailing, and she died on the seventh day. On examination, it was found that profuse hæmorrhage had taken place into the cavity of the peritoneum. It was not confined to the pelvis, and had given rise to suppuration. The point from whence the hæmorrhage proceeded could not be detected, and he could not therefore assert that it was from the ovary. In such a case none but general treatment could be adopted, as there were no symptoms to indicate from what cause the disease arose. In another case, which was under treatment in St. Thomas's Hospital, the subject was an over-worked servant-girl, somewhat out of health from suppressed menstruation. She had a tumour in the lower part of the abdomen, which was swollen as large as in the seventh month of pregnancy. It resembled pregnancy also in shape. It was painful and tender on pressure; the os and neck of the uterus were healthy. At the end of two months the tumour suppurated, and opened externally in the lower part of the abdomen. The tumour, however, remained of the same size, and of the same stony hardness. There was no vaginal discharge. This case at its termination might be found to bear some analogy to the cases detailed in Dr. Tilt's paper.

Mr. DENOR regarded Dr. Tilt's cases as mere effusions of blood into the cellular membrane, round which a cyst had been formed, and a tumour was the result. Cases somewhat analogous were occasionally observed during parturition, from effusion of blood into the cellular membrane of the vagina.

Dr. CHOWNE would not enter into the discussion, as he had not seen such cases as those detailed, which were very rare; and if Dr. Tilt waited until he could speak largely from his own experience upon the matter, as was suggested by Mr. BROWN, it was probable he would long remain silent. He regarded the cases related as differing in their character, but that generally these blood-tumours were the result of effusion of that fluid into the cellular membrane. He found fault somewhat with the title of the paper, which, strictly speaking, was not on "*pelvic sanguineous tumours*."

Dr. TILT, in reply to Dr. De Méric's suggestion, that some of the cases described might have been cases of aneurism of some large abdominal vessel, observed, that with Dr. Lever's patient he had stated that this was the case, and it might therefore be met with again as a cause of extra-peritoneal sanguineous tumours; but that the other seven cases related could not be confounded with aneurism, for in three out of the seven there were post-mortem examinations, and the other four were related by accomplished observers, able to detect a pulsating tumour, of chronic growth, from those described in the paper. Dr. De Méric also asked whether ovarian inflammation did not play a part in this disease; but Dr. Tilt thought that care should be taken in ascribing every morbid action to one pathological condition, and said that, when taking into consideration the action of the ovaries, we must not think of these organs as they are met with in the dead body, but as seen by Verdier and Dr. Oldham, when accidentally placed outside the inguinal canal, in which case, at the menstrual periods, they have been observed to swell *enormously*; that we must think of the softened state of the ovarian tissue surrounding the rent follicle of the ruptured capillaries, attested by microscopical observers, and also of the ruptured bloodvessels seen by them. Dr. Tilt believed, with the French authorities already quoted, that in these cases of *intra-peritoneal sanguineous cysts*, the blood

trickled from the rent capillaries, and falling into the recto-peritoneal pouch, caused peritonitis, and therefore a cyst containing blood. Such were Dr. Tilt's views of the pathology of such cases. He could not understand how obstructed circulation could account for them, as had been suggested by Mr. Denny; he did not admit that the blood in such cases was merely effused in the areolar tissue, for on post-mortem examinations it was proved that the blood had broken down the areolar tissue, displacing it and the pelvic organs so as to constitute a cyst. Neither could he accept Mr. Brown's explanation, that such sanguine collections were formed by the blood permeating the outward surface of the wound, because, whenever death had afforded an opportunity of investigating the case, a less problematical explanation had been found. Dr. Griffith did not see how fluctuation could be felt if the tumour contained blood, but Dr. Tilt reminded him that in some of the cases, the blood, like menstrual fluid in a distended womb, did not coagulate, being a dark, syrupy fluid. Fluctuation was of course less marked or imperceptible when the blood was much coagulated, and when its liquid portions were absorbed. To Dr. Chowne's objection, that some of the tumours described could not be fairly called sanguineous, since the contents were purulent as well as sanguineous, Dr. Tilt added that the peritonitis, by which the blood was confined in the pelvic cavity, might pass to the stage of suppuration, and then pus would be voided with the blood. It had been suggested by Mr. Brown, that as the cases described were very common, it was a pity Dr. Tilt had not waited so as to build his paper upon his own researches only; but Dr. Tilt replied that his reason for bringing the subject before the Society was the fact of such cases not having been noticed in England; and he considered it a singular circumstance that Mr. Brown should have frequently met with cases of sanguineous pelvic cysts, when he had been informed by Dr. Murphy and Dr. Oldham, that in their extensive fields of inquiry they had not met with them; that Dr. Chowne and Dr. H. Bennet had but seldom done so; and that they were considered uncommon by many French pathologists who, during the past year, had drawn attention to the subject.—*Lancet*.

## CONTRIBUTIONS TO CLINICAL SURGERY.

By ROBERT L. MACDONNELL, M.D.,  
Surgeon to St. Patrick's Hospital, Montreal, &c. &c.

### SUCCESSFUL RHINO-PLASTIC OPERATION.

Mr. —, aged 30, two years ago, in an attempt to save an old man who was maltreated by two strong young men, was knocked down and set upon by these men, and whilst one of them was engaged in kicking and cuffing him, the other attacked him savagely with his teeth, and bit out several pieces from about his face and hands, amongst others, a portion of one ear, and the entire cartilage of the right ala of the nose, leaving but a small portion connected with the upper lip. He recovered soon from the effects of the beating, but the wound of the nose was a long time in healing, and left the nostril exposed on that side. He consulted a surgeon about a year ago, who undertook to remedy the defect by engrafting on the cicatrix a portion of skin removed from the back of the patient's hand. This was accordingly done; the piece was removed, the edges of the wound pared, and the new substance retained *in situ* by means of adhesive plaster, and, as might be expected, no union took place. The patient now despaired of obtaining relief, and resigned himself to his condition, and selected an occupation that required withdrawal from society, for the annoyance he experienced from the examination and curiosity of strangers was very distressing to him, being of a peculiarly sensitive and retiring disposition. He happened, however, to hear of a case in which I had remedied a somewhat similar defect, and determined to come to Montreal to consult me. On his removing the adhesive plaster with which he had concealed the deformity, I was struck with the peculiar size and shape of the deficiency in the nostril, which could

hardly have been produced in any other way than that already mentioned, and in reply to my question, he admitted the fact. I recommended him to take a private ward in St. Patrick's Hospital, and stated my opinion that an operation would remedy the defect. Accordingly, on the 4th of October, assisted by my colleagues, Drs. David and Howard, and by Dr. Walter Jones, I proceeded to perform the operation in the following manner:—A small, narrow-bladed knife (which I had found extremely useful in another rhino-plastic case, operated upon in the hospital a few days before) was introduced between the skin and nasal bone, and carried upwards towards the edge of the orbit, care being taken to keep the blade close under the skin. When the point was felt in this situation, the edge was carried towards the mesial line so as to separate the integument from the bridge of the nose, which was rather prominent. The dissection, being completed in this situation, the knife was carried downwards, still close under the skin, until it reached a level with the under edge of the nasal bone. The blade was then withdrawn, and entered under the remnant of cartilage before alluded to as being still connected with the cheek, and pushed towards the ear for about two inches, when the edge was turned upwards, the dissection carried on until it joined that before made. By this plan the skin was detached off the subjacent parts, from the median line of the nose all over the cheek, and the scalpel passed freely about in all directions. Having thus made a large flap, the edges of the cicatrix were pared and brought together, and the stump of cartilage joining the cheek being brought into contact with the tip of the nose, was there maintained by a Dieffenbach's pin and twisted suture; two or three points of suture served to bring the remainder of the wound in apposition, and thus what was before a semilunar cicatrix appeared an incised wound, whose edges were in one line. To enable me to avail myself more fully of the flap detached from the cheek, an incision to the extent of a little more than half an inch was carried from the outer edge of the nostril, by which the tension was taken off the new ala nasi, and a plug of lint being introduced into the nostril, the dressing was completed; the loose integument being shoved from the cheek towards the nose, and there retained by means of compresses and adhesive plaster.

The operation was in this manner performed, without making the least disfigurement of the face; nothing remarkable ensued during the month the patient remained under treatment. The needles and sutures were removed on the fifth day, union having taken place, but the remainder of the wound continued to suppurate for the next fortnight. He now has a complete nostril; the nose is straight and prominent, and except that on the side operated upon, the lower edge of the ala nasi, at its junction to the cheek, descends about the twelfth of an inch more than the other, no difference is perceptible, as nothing marks the line of junction but a fine cicatrix, which has little appearance of being the result of a surgical operation.

The plan of operation in the foregoing case, is a modification of the French method of "autoplasty," or, as it is sometimes termed, *la methode par glissement*. It differs, however, from the French method in the fact of the dissections being subcutaneous, which, it is hardly necessary to mention, is a decided improvement; for it is often a question whether the plan adopted to remedy some of these deformities does not leave a greater amount of disfigurement than that for which the operation was undertaken; and the practitioner who has only seen drawings and woodcuts of rhino-plastic operations, can have but little idea of what shapeless masses of flesh even the most successful of them are when a whole nose has to be made. But when a portion only of the nose is lost, then, as in the instance before us, the deformity admits of being remedied. The plan I adopted is, beyond measure, preferable to that of taking a flap from the cheek, twisting it round, and adapting it to fill up the chasm; for, besides the scar on the cheek, the want of any portion of cartilage prevents a nostril being successfully made, so that whenever the surgeon can save a piece, no matter how small, of the original

ala, he will find that it can be made to answer better for a margin than any piece taken from the cheek; for besides rounding off the arch of the nostril and keeping the ala distended, it retains the property of dilatation and compression, owing to the insertion of the levator labii superioris alaeque nasi being attached to it, as well as the lower fibres of the compressor nasi, and it is acted upon simultaneously with that of the opposite side, both in the acts of respiration and the different emotional movements of the face. These peculiarities are well marked in the above case, and though not pointed out before, are, in my mind, of some importance, and tend materially to the success of the operation, and to improvement of the patient's appearance. Although I have mentioned that the foregoing operation is a modification of the French method of "autoplasty," yet it does not appear that French surgeons have ever availed themselves of the flap made by subcutaneous dissection; and it is evident that the most recent writer on the subject is unaware of the possibility of the defect being remedied in this manner, for Jobert says:—"On a réparé également par la méthode indienne le lobule du nez et même, dit-on, les ailes du nez. Pour moi, sans blâmer l'emploi de la méthode indienne pour réparer les difformités partielles du nez, je pense que lorsqu'il s'agit de son extrémité ou de ses ailes, il est préférable de tailler un lambeau aux dépens des joues ou des lèvres."—*Traité de Chirurgie Plastique*, tom. i., p. 256.

#### SUCCESSFUL GENO-PLASTIC OPERATION.

—, aged 45, applied to me for advice concerning an ulcer on the left cheek, which was evidently a genuine specimen of "Jacob's cancer of the face." It had commenced seven years before as a small, scaly growth, about half an inch from, and on a level with, the commissure of the lips; on this a scab used to form, and remain on until accidentally removed. When once the ulcer was formed it exhibited no disposition to heal, and though its appearance would become improved under different plans of local treatment, it had never cicatrized, and though stationary for several months at a time, it would now and then commence spreading, and at last extended to the size of half-a-dollar. It was not painful at first, but had latterly become so; it had never bled, and the discharge was scanty and not offensive. Though apparently superficial, on close examination the entire thickness of the cheek was found engaged in the disease, the mucous membrane being, however, quite healthy in appearance. The commissure of the lips was free from disease, although quite close to it; and on inquiry it was ascertained that it had never ulcerated nor become fissured. There was no enlargement of the glands under the jaw, and the patient's general health was quite good. Having already applied to various medical men for relief, and meeting with disappointment from all remedies recommended to him, I had little difficulty in persuading him to have it removed, and for that purpose he entered St. Patrick's Hospital as a private patient.

I mentioned to my colleagues that it was my intention to save, at all hazards, the commissure, and, having excised the diseased portion, to make a cheek by the approximation of the edges of the circular wound left after its extraction. Accordingly, the lips were stretched so as to make tense the commissure, and a small knife passed between the mucous membrane and the margin of the disease, and then carried round the latter, leaving a margin of healthy structure attached to the disease. The surfaces of the wound were brought together by the twisted and interrupted sutures, and though I thought, before commencing the operation, that I should be obliged to loosen the upper and lower flaps from the subjacent structures, I had no difficulty in bringing the circular wound into a straight line, so as to resemble a simple incised wound. Cold-water dressing was applied to the cheek, and the patient desired to maintain perfect silence. In a few hours hæmorrhage took place from the mucous surface of the wound, and resisting the astringent powers of a saturated solution of tannin, had proceeded to a considerable extent

before I had time to reach him; but when the edges of the inside of the wound were brought closely together by three points of suture, it immediately ceased. The patient now informed me that he and all his family exhibited the hæmorrhagic diathesis, and that on one occasion he had nearly lost his life from the bleeding that followed the extraction of a tooth whilst in the Limerick Infirmary.

Five days after the operation the needles were removed, the inside sutures were allowed to remain *in situ*, and the union being now complete the parts were well supported by adhesive plaster and collodion,\* and the patient allowed to return home.

I have recently seen the patient, and nothing but a cicatrix on a line with the commissure is perceptible. The features of that side of the face are quite natural, and he has perfect use of the cheek. There is not the least sign of disease on the commissure, though eight months have now elapsed since the operation was performed. This fact I am anxious the profession should have brought before them, for it corroborates a statement made by Professor Serre of Montpellier, that the mucous membranes in the immediate proximity of cancerous growths, or even covering them, exhibit but little proneness to become implicated in the disease, and consequently should be preserved for a covering in all cheilo-plastic operations for the flaps with which the new lip is to be made. Being aware of this important discovery, and also knowing how difficult it is to form a good and useful commissure, I was particularly anxious to save the natural one, and was fortunate in so doing; though, had I not known the useful fact stated by Serre, I should certainly have removed it in connexion with the disease. I have at this moment a patient with cancer of the lip, in whom the removal of the disease will necessarily involve cheilo-plasty; and as the case affords a good opportunity for testing the correctness of Serre's statement, I will lay the result before my readers on some future occasion. In conclusion, I may state that the disease exhibited a true specimen of cutaneous cancer; and I cannot agree with the views recently advanced that Jacob's ulcer is a species of lupus, that it is, in fact, *lupus devorans*, though this opinion is advocated by so accurate an observer as Dr. Neligan, whose recent work on cutaneous diseases has just reached us; but to this subject I will draw the attention of the readers of this journal in the next number.—*Canada Medical Journal*.

\* Though the remarks of Professor Syme concerning the impropriety of using collodion in the first instance when we endeavour to procure primary union, are quite in accordance with my own experience, yet I have found it a most excellent remedy in keeping up tension and approximation, after needles and sutures are removed. When collodion was first introduced, I used it in addition to sutures in two cases in which I had amputated the breast, having read such flattering statements of its successful employment in similar cases. But to my great disappointment, the edges of the wound, though closed and apparently united, became prominent and inflamed, and on some of the collodion being detached, a large quantity of pus escaped in both instances, to the great relief of the patients; and the wounds which, under other circumstances, I have no doubt would have united by primary union, to a great extent healed by the slow process of granulation. The results of the use of the remedy in these cases, had induced me to abandon it in all cases as a means of uniting the edges of a recent wound; but where we have removed sutures and needles it will be found a valuable remedy, care being taken to leave spaces for the discharge to escape.

CHANGES IN THE MANAGEMENT OF THE PARIS HOSPITALS.—*L'Union Médicale* mentions that the great facility for travelling has so encumbered the hospitals of Paris, that measures will now be taken to make the various departments pay for the people from the provinces who are admitted into the Paris hospitals. The Central Board, which was formerly instituted merely for examining and sending patients to the various hospitals, will now be transformed into a dispensary, without detriment to its former duties; so that the poor who can be treated at their own residences may be attended to. It should not be forgotten that the municipal body of Paris contributes £350,000 to the expenses of hospitals.

# SILICIOUS DEPOSIT IN THE URINE, SUPPOSED TO BE FROM THE USE OF NEW SPONGE.

By HENRY JOHNSON, M.D.,  
Senior Physician to the Salop Infirmary.

Silicic acid is a well-known constituent of natural urine and of urinary calculi; and it is always found in urinary concretions derived from brutes, according to Wurser and Lapaigne. But although, on the authority of these names, the occurrence of silex in urinary deposits and concretions may be deemed possible, this event is at any rate extremely rare; and, unless under peculiar circumstances, would be ascribed to accident, fraud, or mistake. I have, however, seen it, where the parties were far above all suspicion of any intention to deceive, and where the patient was too young and girlish to be the subject of that morbid pruritus, which probably leads to the voluntary introduction of foreign substances per vaginam.

As every case is of importance which proves a fact, or points out an obvious source of error, I think the following history is worth recording:—In 1850, I was desired to examine a small portion of white powder, which I understood was a deposit from urine; it had all the chemical characters of silex, and scratched glass with facility. I was informed, that notwithstanding every precaution having been taken to avoid error, more or less of this powder had been found at the bottom of the utensil for about a fortnight. I afterwards saw the patient. She was 11 years old, of spare habit, but tall for her age, and by no means strong. She was subject to sickness and anorexia; the bowels were torpid; the tongue was not clean; the catamenia had never appeared. At the time of my seeing her the silicious deposit had ceased. The urine was pale, had a specific gravity, verging from 1011 to 1031, there was a light mucous cloud in it, and it contained some prismatic crystals of triple phosphate, and on another occasion urate of ammonia and a large quantity of urea. The most distressing symptom was a most constant desire to pass water, by day and by night, so that she could not rest, and if the desire was not speedily gratified, the urine escaped involuntarily.

There appeared to be no organic disease present in this case, and the patient ultimately got well without any remarkable symptom or treatment. I feel quite satisfied that there was here no endeavour to impose upon her medical attendants, either on the part of the patient or her friends. The silicious deposit I have no doubt arose from the use of a new sponge. A silicious powder (quartz) is always found in sponge when new, and I have since seen a large quantity of this sort of dust, which had fallen out upon the shelf in a chemist's shop where these articles were kept; it is nearly pure silex, because sponges are prepared for sale by being soaked in dilute muriatic acid, which removes calcareous particles, and leaves such as silicious.—*Prov. Med. and Sur. Jour.*

## ON THE BOUQUET OF WINE.

By Dr. F. L. WINCKLER.

In his recent experiments on the vegetation of plants, Winckler has arrived at very satisfactory results explanatory of the specific odour peculiar to the various sorts of wine produced in different districts, which is known by the expression of "blume," or "bouquet." If about half a pint of any sort of grape-wine be evaporated in a porcelain vessel by means of steam, until not only all the spirit of wine, but also the æthanitic ether, and in general all parts volatile at this temperature (80 deg. R.) are evaporated, a thickish liquid of more or less dark colour, and of a peculiar, pleasant, acidulo-vinous odour remains behind, from which, after it has become cold, a greater or lesser quantity of tartar separates. By diluting this liquid with water, so that the weight of the solution is about a quarter of a pound, and subjecting the solution with an equal weight of fresh burnt lime to distillation, there is obtained even during the slacking or hydrating of the lime a very agreeable and intensely smelling distillate which, like ammonia, is a strong base, and forms with acids neutral salts, possessing in a

high degree the odour corresponding to the so-called "bouquet" of the employed wine. This fact suggested the idea that this compound may be in a similar manner contained in the wine itself, and the supposition was fully corroborated by experiments. If the residuary lime of the evaporated wine be treated with water after the conclusion of the distillation, the solution filtered, and the filtrate distilled with a small quantity of moderately strong sulphuric acid, a new volatile acid of a highly specific, almost balsamic odour is obtained, which being neutralized by the necessary quantity of the first obtained nitrogenous base, yields a neutral volatile salt, which possesses the peculiar odour ("bouquet") of the employed wine in the highest degree. There is, therefore, no doubt that this compound is not only contained as such in the wine, and constitutes the "bouquet," but that it is this nitrogenous compound which determines the chemical constitution, the durability, and all those changes to which it is subject by keeping.—*Phar. Jour.*

## NEW FORM OF ITCH.

M. BOECK of Christiania has observed a new form of itch in a girl aged 15. The patient presented in the palm of the hand, the clefts between the fingers, the nails, the soles of the feet, the gluteal and dorsal regions, thick crusts, which were speedily reproduced when detached by the action of hot water. Vesicles and pustules were scattered in various places, and the hairy scalp was likewise occupied by the same crusts, which had been growing for the last two years. M. Boeck was much embarrassed as to the diagnosis, and at last bethought himself to subject particles of the crusts to microscopical examination. He was surprised to find that they were composed of a multitude of acari, with their eggs and excrements. But the disease presented nowhere any furrows, nor the acarus alive. Nevertheless, the girl contrived to communicate the affection, first to the patients in the beds next to hers and the nurses, and afterwards to almost every person in the ward. All these people got rid of the disease by using Vienna ointment, as did also the patient, after she had suffered from a general pustular eruption. M. Cazenave, to whom M. Boeck sent some of the crusts, also examined them with the microscope, and found them composed of entire acari, fragments of the insect, eggs, &c. M. Cazenave, who has inserted the case in the "Annales des Maladies de la Peau et de la Syphilis," considers it very curious, and of a unique kind, especially if one considers the absence of the live acarus, the non-existence of the furrows, the reproduction of acarus crusts, under an epidemic layer on a surface first thoroughly cleansed, the rapid spread of the disease in the ward, and the cure effected by a simply local treatment. M. Cazenave adds, that this case clearly proves that we are far from knowing everything concerning the acarus, and have much to learn on the symptomatology and ætiology of the itch.—*Lancet.*

## REVIEWS AND NOTICES OF BOOKS.

PULMONARY CONSUMPTION AND ITS TREATMENT. By W. M. BURSLEM, M.D., Licentiate of the Royal College of Physicians, and Senior Physician to the Blenheim Dispensary, London. 1852. 8vo. pp. 156.

ONE of the principal objects contemplated by the author in this publication is, to recall attention to an old method of treatment in phthisis—viz., that by emetics; and to illustrate its advantages in the incipient stages of the disease. "From my first entrance on the duties of medical officer, I resolved (Dr. Burslem, in the preface to the volume before us, observes) to pay particular regard to the earliest and most remote period in the history of the case. For this purpose, I directed serious attention to hereditary predispositions to disease; and wherever I found such to exist, I assiduously directed my efforts to combat this influence. I took advantage of the field now opened to me of trying, under well-regulated restrictions, certain methods of treatment formerly resorted to in certain cases, but which I found to be now discontinued, for what reason I know not."

"It was thus, with the assistance of my friend Dr. Ross, that I took up the subject of emetics, from which I have since derived so much assistance in certain conjunctures of this disease. In the treatment of pulmonary affections in

the male subject, I found myself agreeably surprised at the happy results which thus attended my incipient efforts. I continued my exertions in the same course with even increased success; but if this newly-adopted plan of proceeding proved so successful in arresting the disease in the male, how much more satisfactory was it demonstrated in the management and treatment of pulmonary disease in the case of females. Here, from the more complicated nature of the female economy, a more strict investigation, a more detailed examination into many particulars became necessary, which ever exert a most important influence on the delicate constitution of the female."

The author's description of tubercle, and of the symptoms of phthisis, is concise and accurate, but does not require any remark at our hands. In the section upon its causes, Dr. Burslem, after alluding to the greater frequency of phthisis in the female than the male, gives a table of 118 cases of phthisis, in which the age at which the menses made their first appearance, and the period of its duration, are stated; from which it appears that—

In	3	it occurred at the age of 10 years.

"In 4 of these cases it lasted two days; in 16, three days; in 22, four days; in 19, five days; and in 43, it continued beyond six days. Of the remaining 14 the duration was not known. In 61 the discharge was profuse, and in 68 leucorrhoea was complained of; thus pointing out the close connexion between abnormal menstruation and phthisis."

The influence of occupation or profession in developing phthisis is alluded to at some length by the author. The persons particularly exposed to contract phthisis are, according to Dr. Burslem, the following:—

"Individuals obliged to make great exertion with the voice or respiration; actors, singers, lawyers, players on wind-instruments, &c.; workmen exposed to arsenical or mercurial vapours; earthenware manufacturers, painters, founders, &c.; workmen exposed to metallic, vegetable, or animal dust; metal polishers, plasterers, stone-cutters, wool-carders, &c.; workmen having to perform extensive and continued movements of the upper extremities; bakers, paviours, carpenters, blacksmiths, &c. By far the most numerous of the cases met with in London are amongst tailors in men, and milliners in women. Amongst the latter I find too numerous and painful instances where young females rise at five o'clock, work all day in an ill-ventilated and confined apartment, frequently till one o'clock of a morning, and besides this are badly fed."

The profession is indebted to M. Lombard for many valuable details under this head, and the following conclusions, laid down by him, are quoted by the author:—

"1. The poor classes of society are twice more accessible to phthisis than the easy and affluent.

2. A sedentary life brings a much greater number to phthisis than an active life.

3. Great movements of the arms appear to diminish the frequency of phthisis in sedentary states, and to increase it in the active professions.

4. The constant exercise of the voice seems rather to diminish than to increase the number of phthisical subjects.

5. The curved position seems rather to favour the development of phthisis.

6. Phthisis is twice more frequent in workmen confined in workshops than among those who work in the open air.

7. The air which is charged with watery vapour seems to preserve from phthisis.

8. A hot and dry atmosphere favours the development of pulmonary tubercles.

9. The air charged with animal emanations preserves from phthisis.

10. The air charged with the emanations of fresh plants is a preservative from phthisis.

11. The air charged with the emanations of acid or alcoholic fermentation exerts but a questionable influence.

12. The air charged with emanations given off by varnishing, turpentine, drying oils, exercises a very fatal influence.

13. The different gases which escape from charcoal in combustion seem to favour the development of phthisis.

14. The mineral vapours (those of lead, mercury, antimony, arsenic, copper), the mineral acids, do not seem to be causes of phthisis.

15. The air charged with foreign bodies, as with dust, exerts in general an injurious influence, but the effect varies according to the nature and division of the foreign bodies."

In recommending emetics in phthisis, "it is not at all pretended (the author observes) that such employment is by any means novel; but it may fairly be considered an interesting subject to account for the fact, why a remedial agent which at one time enjoyed such popularity among the profession has been so much overlooked of late years, did we not know that fashion, in many instances, regulates even medical practice."

Dr. Burslem says that at first he was in the habit of giving ipecacuanha and zinc; but finding their depressing effects to continue for some time, he substituted for them the essence of ipecacuanha, either with or without chloric ether. "Administering these preparations in the dose of about fifteen minims in a teaspoonful of water, I direct the patient (he says) to drink some warm water; in about ten minutes or a quarter of an hour after, vomiting takes place, and in general it acts but once." "Seldom any depressing symptoms remain, and the patient is frequently enabled to take breakfast within half an hour, and not unfrequently to enjoy it more than had been the case for months."

"The emetic is usually administered in the morning; the cough most frequently being the most troublesome and the expectoration most copious at that time. Still, when the rest has been disturbed from the frequency of the cough, their employment at night has, in several instances, been followed with favourable results. In their operation a quantity of phlegm is frequently brought up; occasionally some thick, white, lumpy matter, very commonly some bile, and but very rarely any blood. The phlegm, generally, by degrees diminishes, as does the bile. The patients say (it may be fancy) that they think they breathe more freely; the cough very commonly diminishes in frequency, and the appetite improves. The emetics are generally repeated at first every third day, after a while every fourth, and then once a week.

The cases in which the most benefit will be found are those in the early stage of the disease, before the deposition of tubercular matter in the lungs has gone to any great extent, when emaciation has been for some time going on, the chest is becoming flattened, the breath is short, there is tightness of the chest, an inability for exercise; when there is also an increase of the action of the heart on the least exertion, and pain or uneasiness after meals."

After some remarks upon the other remedies employed in phthisis, and cod-liver oil in particular, the author illustrates his views and the results of his method of treatment, in a series of cases, twenty in number, with which the volume concludes.

#### ANEURISM AFTER VENESECTION CURED BY FLEXION OF THE LIMB.

M. A. THIERRY has lately published, in the *Revue Clinique*, a case of false aneurism at the bend of the elbow, occurring after bleeding from the arm, which he successfully treated in the following manner:—The arm was forcibly flexed, the limb carried over the head, and the hand fixed on the opposite cheek. The patient remained in this painful position for five days, after which time it was changed to that which M. Velpeau generally adopts for fracture of the clavicle—viz., the arm fixed across the chest, and the hand resting on the opposite shoulder. A fortnight after the beginning of this treatment, the tumour was reduced to the size of a nut; the arm was then kept in the same position for another fortnight, after which no sign of any pulsating tumour remained. M. Nélaton, who saw the patient, considered the case a very remarkable one, as the aneurism has disappeared, and the vessel remains permeable at the seat of the wound. M. Thierry

very justly says, that one case is not sufficient to prove the efficacy of any method of treatment, but that the results here obtained are well worthy of attention; he thinks that further trials will perhaps lead surgeons to treat aneurisms of the limbs by forced flexions; femoral aneurism by flexion of the thigh upon the pelvis, and popliteal aneurism by flexing the leg upon the thigh. If we mistake not, M. Thierry's method is founded upon the principle of pressure, and carried out with a great deal of pain and inconvenience to the patient. If the flow of arterial blood through the sac can be graduated, moderated, and rendered very slow by simple and painless means (as is proved by experience), it is cruel to torture patients by placing them for a whole month in the position given by the immortal statuary to Laocoon. — *Lancet*.

## MEDICAL EDUCATION.

### ADDRESS TO THE MEDICAL PROFESSION OF VIRGINIA.

There were but two measures definitely acted upon by the society during its last session, which we think should be embraced in this address: 1st, the recommendation to the legislature to enact a law requiring the registration of births, deaths, and marriages; and 2nd, the recommendation to the same body to establish a state board of medical examiners, whose approval should be necessary to entitle any one to practise medicine in the state. But there are two other measures, not specifically brought before the society, which we deem of great importance to the honour and prosperity of our profession, and absolutely necessary to the maintenance and successful prosecution of the other measures of reform already indicated, and which, we have reason to believe, would have met with the entire approbation of the society had they been before it. We refer to the establishment and strict observance of a uniform code of medical ethics, and to the thorough and efficient organization of the profession. We would direct your attention to each one of these measures in succession.

1st. The necessity of the establishment and strict observance of a uniform code of medical ethics. The importance of this measure is so obvious that we need scarcely dwell upon it. There is no physician, more especially in the country, who does not often feel the want of it, and who, in consequence thereof, does not frequently find himself embarrassed in his conduct either towards his brother practitioner or towards his patient. So important did the National Medical Association consider this subject, that at its first meeting a committee was appointed to prepare a report upon it. This duty the committee performed by presenting, at the next meeting of the association in Philadelphia, an elaborate and most carefully prepared code of ethics, proposing to the profession the rules which should govern the conduct of its members in all their relations as medical men. This report was unanimously adopted by the association, and its adoption recommended to the state medical societies.

This measure was also the subject of action by the Medical Society of Virginia some years since, when a most excellent code of ethics was prepared and adopted by that society. During the last few weeks, by order of the executive committee of the society, a number of copies of this code have been issued for the purpose of giving it a general circulation among the members of the profession throughout the state, and we would most respectfully, but earnestly, urge upon every medical man in the state to provide himself with a copy of it, with the full assurance that the justness of its recommendations and the evident propriety of its regulations will ensure its strict observance by every honest member of the profession.

2nd. A more thorough and efficient organization of the profession. This subject we regard as second in importance to none which has engaged the attention of the profession during the last few years. Indeed we consider that unless some measures are adopted for the purpose of effecting this object, no permanent impression can ever be produced by the efforts which are now being made at medical reform. Individual action can accomplish but little. It is only by the concerted action of a united body that aught of magnitude and of importance can be effected. The more thorough organi-

zation of the medical profession was one of the grand objects had in view in the formation of the National Medical Association; and this body has repeatedly urged the necessity of a more thorough organization of the profession in the separate states. In our state it has been a subject which has commanded much of the attention of the profession for several years past. In the State Medical Convention which assembled in Richmond in December, 1846, a committee was appointed to prepare a plan for the organization of the profession in the state. That committee, looking to the ample powers conferred by its charter upon the Medical Society of Virginia, thought that the proposed organization ought to take place under the auspices and through the instrumentality of that society, and reported to the convention that the subject be referred to the Medical Society of Virginia. That society, composed at that time almost exclusively of members of the profession from Richmond and its vicinity, took up the subject, and had presented to it, through a committee, a carefully prepared plan for the organization of the profession of the state under the charter of the society. This plan was rejected, and no substitute was at that time offered. By a subsequent action of the society, however, the material features of the plan referred to were incorporated into its constitution; but the interest which had been previously exhibited by the profession throughout the state in the subject had then very much subsided, and no steps were taken to second the action of the society. But about eighteen months ago, the society, observing in the profession in the state at large unmistakable evidences of a desire to organize, again took the subject into consideration, and presented to the profession the system which is now in operation, and by which the Medical Society of Virginia, with its charter, its rights and privileges, has been transferred from the physicians of Richmond and its vicinity to the profession of the whole state, to whom of right it has always belonged. In the Medical Society of Virginia, as at present constituted, there have been already enrolled a little less than 450 members of the profession of our state; and there can be but little doubt that a few years will see almost the entire medical corps of the state organized into one harmonious and efficient body. Such a body, representing it will all sections of the state and all medical interests of the state, and combining as it will the medical talent and influence of the whole state, cannot fail, in its annual deliberations, to exert a wholesome influence upon the profession, and to uphold and elevate the true interests of medical science.

In accomplishing thus much towards the organization of the medical profession of Virginia, we have reason to congratulate ourselves. But we have only made a beginning in this important work; we have but laid the corner-stone upon which the superstructure is yet entirely to be erected. The general organization of the profession into one central body, however desirable in itself, and however necessary as a starting point for future action, will have but little effect, unless it be followed by the local organization of the profession in the various towns, counties, and districts of the state. Of the great mass of the profession in the state, but few, comparatively, can attend the meetings of the state society, or can be directly benefited by this central organization. These meetings, too, occur only annually—too seldom to allow of the transaction of any other business than that connected with the interests of the profession of the state at large. The only means, then, left to the large majority of the members of the profession for deliberating among themselves upon professional subjects, or for regulating their professional affairs, will be the organization of local medical societies. And this work also has already been begun. There are now, in most of our larger towns and in several counties, local societies in a flourishing condition, organized with a view of advancing the true interests of the profession, and of coöperating with the State Medical Society and with the National Medical Association in the work of legitimate reform. We would, therefore, urge upon you most earnestly the formation of such societies in every town, or county, or district, in which a

sufficient number of regular medical practitioners can be convened for the purpose.

3rd. The recommendation to the legislature to enact a law as speedily as possible to carry out the provision in the new constitution of the state requiring the registration of births, deaths, and marriages. This subject, of such vast importance and of so great interest, not only to the medical man, but also to the political economist, and which has long been the subject of state action, with many of the nations of Europe and with two of our own states, was, in obedience to a recommendation of the National Medical Association, brought to the attention of the Medical Society of Virginia during the last year. A committee was appointed to present the subject to the legislature, the result of whose labours was a bill, the provisions of which were well adapted, in our opinion, to secure the objects in view. During the consideration of this bill by the house of delegates, a successful motion was made to recommit it, with a view of striking out or altering one of its most important features, *viz.* the provision requiring physicians to report the deaths occurring in their practice. This proposed amendment to the bill was condemned by the unanimous vote of the Medical Society of Virginia during the last annual meeting, in the adoption of the following resolution: "That this society has learned with regret that the bill before the house of delegates, in reference to the registration of marriages, births, &c., has been seriously objected to and recommitted to the committee for such amendment as is calculated to destroy the efficiency of the law and render it wholly inoperative for good, both to the profession and to the state at large; and this society earnestly recommends to the legislature the passage of the bill in the form in which it was originally presented for its consideration by the committee." We feel assured that this measure, thus unanimously recommended by so respectable a body as the State Medical Society, may be passed by the legislature, if the members are accurately informed with regard to the objects proposed by it. We therefore would suggest to each member of the profession in the state to make such representations to the delegates and senator from his district or county as may be necessary to inform them with regard to the objects proposed by the measure, and to urge upon them the importance, not to the medical profession so much as to the public welfare, of the adoption of the means proposed, of requiring the regular, uniform, and systematic registration of births, deaths, and marriages.

4th. The recommendation to the legislature to establish a board of medical examiners for the state, before whom every candidate for the practice of medicine or surgery shall appear for examination, and whose approval shall be necessary to entitle any one to practise these branches in the state. This has been justly regarded as the most important measure of medical reform proposed by the society, and its consideration occupied a larger portion of the time of the society than did any other subject. It is not our duty to discuss the propriety or the policy of this most serious change in the mode of admitting members into the ranks of the medical profession. The subject has been acted upon and decided by the Medical Society, and it is our duty only to put you in possession of the exact nature of that action, and to suggest to you some of the grounds which have led the society to determine upon it.

This subject (the separation of the teaching from the licensing power) was brought to the consideration of the State Medical Convention, to which reference has already been made, of 1846, and that body, after a full discussion of the subject, adopted the following resolutions:—"That this convention feels the necessity of some radical change in the admission of candidates to the right to practise physic in this state." "That we instruct our delegates to the National Convention in Philadelphia, to be held in May next, to use their utmost exertion to carry out the spirit of the foregoing resolutions." Since that time the attention of the profession has been almost constantly directed to this measure. At every meeting of the National Medical Association, we believe, it has been a subject of con-

sideration, and several able and elaborate reports are to be found upon it in the Transactions of that body. It seems to be generally conceded that the system of medical education in our country is defective, and that evils exist in that system which ought to be remedied, if possible. We are not among those who think that the honourable profession to which we belong is yet entirely degraded. Nor do we think that the medical schools of our country are yet entirely corrupt. We have no sympathy with those who would have you believe that the profession of which they are themselves members is already sunk below the level of the commonest trade, and who would persuade you that the respectable body of medical men who occupy the chairs of our schools are for the most part unscrupulous adventurers, insensible to the high dignity of the profession, and only alive to their own sordid interests. At the same time we believe there are serious evils existing in the profession, many of which may be traced to errors to be found in the schools—errors which it is the duty of the profession to examine into, and to endeavour to correct. Nor are the schools themselves insensible to these errors. In the National Association the faculties of the most respectable schools have honestly confessed them, and have expressed their willingness to adopt any practicable measures of reform in which they would be sustained by the profession of the country. In reference to the schools of our own state, we feel authorized to say, in behalf of the two largest of these schools (with the others we have had no opportunity of conferring), that they are fully sensible of the defects in the present system of medical education; and that while they have been endeavouring already, to some extent, to remedy these defects, they will heartily concur with the profession of the state in carrying forward every practicable measure calculated to advance the interests of the profession, and to benefit the cause of medical education.

The important practical question which is now presented to the profession is, What practicable means can be adopted to remedy these defects? By what means can we render our system of medical education more perfect and more thorough, and how can we best protect the community from the danger of having imperfectly educated physicians thrown among them? The experience of the past six years has demonstrated that the mere recommendations of associations, state or national, will have no effect. Without a concerted action on the part of all the schools to carry out these recommendations in good faith, which it is now impossible to obtain, none of them can attempt it without great danger of their own destruction, or at least without involving a greater loss than we can reasonably expect them to encounter. Students will naturally seek those schools where they can obtain their diplomas most readily; and as long as no other qualification than the possession of a diploma is required, either by the community or by the government, to entitle one to practise medicine, this must necessarily be the case.

Now, the remedy for this evil is, obviously, the requirement, on the part of the candidate for practice, of a certain degree of proficiency in his profession, to be judged of independently of his diploma. This requisition must be made either by the community or by the government. The community cannot do it, for they have no means of judging of the qualifications of a candidate for practice. They can only test his qualifications by long experience; and even then, we know, that they are very liable to form erroneous judgments. It hence becomes necessary that some action should be taken, on the part of the government itself, to require those persons who desire to practise medicine in our state, to submit their qualifications to the test of some uniform standard.

Being fully convinced of the necessity for some such action on the part of the government, the Medical Society of Virginia, during the last winter, appointed a committee to memorialize the legislature of the state to institute a board of medical examiners. The result of this action was the introduction into the senate of a bill for that purpose, the chief provisions of which were the following: The election by the Medical Society of Virginia, at its

first annual meeting after the passing of the act, by ballot, of eleven physicians of established skill and reputation, seven of whom to be appointed by the governor, to constitute a board of medical examiners for the state. The members of the board to hold their office for three years. Vacancies to be filled by the governor from the remaining nominees, or, if more than five vacancies, by the other members of the board. The board to hold two sessions annually, one in Richmond the first Monday in May, the other in Lewisburg the first Monday in October; and the board to have power to appoint its own officers, &c. Each member of the board to take a prescribed oath before a justice of the peace for the faithful discharge of his duties. The board to examine thoroughly, fairly, and impartially all persons who may properly apply to them, on anatomy, physiology, surgery, the principles and practice of medicine and obstetrics, materia medica, pharmacy, and chemistry, and to give a certificate of qualification to all whom they may find possessed of a competent knowledge of these subjects. No certificate to be issued by the board except by the concurrent votes of five of its members present at the time of the examination, and the board to enter upon a book the names of all persons to whom they shall give certificates, with their places of residence, &c.: the same to be published in two newspapers of the state within thirty days after the adjournment of the board. No licence to practise medicine or surgery to be granted to any one until he shall have obtained a certificate from the board. Any one attempting to practise without such certificate shall forfeit and pay, for every prescription, a sum not less than fifty dollars nor more than one hundred, to be recovered with costs of suit by action of debt in any court of judicature within the county where the offence is committed, one-half to be paid the prosecutor, the other to be paid into the treasury of the county where the offender resides. The certificate to be registered in the clerk's office before any licence is issued. The clerks to file and preserve the certificates, receiving twenty-five cents for doing so, and the same sum for every copy of said certificates. Each applicant for examination to present a certificate of good moral character, and of his being twenty-one years of age; also to pay to the treasurer of the board twenty dollars, the payment of which not to be contingent upon his obtaining a certificate of qualification, and in no case to be paid more than once. Any member of the board may be expelled by a vote of five members of the board, but may be reinstated by the Medical Society of Virginia. The medical society may impeach or expel any member of the board. Each acting member of the board to receive four dollars per day while the board is in session, and ten cents mileage. The treasurer to deposit annually the surplus funds to the credit of the commonwealth. All practitioners of medicine and surgery, previous to the passing of this act, to be exempt from the provisions requiring a certificate of qualification, and to obtain their licence in the mode prescribed by law. The act to take effect on and after the 1st of January, 1853.

At the last annual meeting of the Medical Society of Virginia, the merits of this bill were brought fully under discussion in the consideration of the following resolution:—“That we approve in the main of the bill reported by the committee of the senate, as probably the best that can be done at present, but that it will be the aim and pleasure of the society, through its nominees for this board, constantly to increase the stringency of its provisions and to elevate the standard of acquirement.” The principal objections urged against the bill were founded upon that provision which allows all persons, without discrimination, to apply to the board of examiners for a certificate, requiring no preliminary education, either scientific or medical, of the candidates. It was argued that instead of constituting a safeguard against the entrance of unqualified persons into the profession, the creation of this board might be the means of throwing wide open the doors of the profession for the admission of all who choose to enter. In order to obviate this and other objections which were suggested, the following substitute for the above resolution

offered, and after full discussion adopted:—“That whilst the society approves the main features of the bill now before the senate of Virginia, providing for the appointment of a state board of medical examiners; they respectfully suggest to the legislature the propriety of requiring, as a condition precedent to every examination, that the applicant shall have been graduated in medicine, or that he shall have attended two full courses of lectures in some respectable medical college, and that the examinations by the board shall be open to the presence of the medical faculty of the state.”

By this action of the Medical Society of Virginia, the profession of the state, so far as it was embodied in that society, has pledged itself to the support of the scheme for the establishment of a board of medical examiners, requiring, however, that all candidates for examination before that board shall either be graduates in medicine, or shall have attended two full courses of medical lectures, and that the examinations shall be public.

We have thus placed before you, as plainly and as impartially as possible, the present position of this most important question before the profession of our state. It is for you to say whether you will concur with the society in urging upon the legislature the adoption of this measure. If you think as they do, that by it the interests of the profession and of the public will be materially advanced, and that the sacred portals of the temple of medicine will be thus more effectually guarded from the intrusion of unworthy and unqualified persons, it is your imperative duty to exert to the utmost your influence upon the members of the legislature in order to secure its success.

Such are “the measures of medical reform” which we have deemed it our duty to bring to your attention. Of their importance, we conceive that no physician, who has the interest and honour of his profession at heart, can doubt. Their practicability, we think, can scarcely be questioned. All that is necessary to secure their adoption is a united and continued effort of the physicians throughout the state. And we would most earnestly appeal to you, as members of a profession which should be second to none in all that tends to elevate and benefit man, to come up to this work, and honestly to labour to place that profession in the position which of right it ought to occupy.

## MEDICAL PRESS.

“SALUS POPULI SUPREMA LEX.”

DUBLIN: WEDNESDAY, DECEMBER 22, 1852.

### CURIOSITIES OF MEDICAL EVIDENCE.

We this day reprint from the daily journals the report of an inquest, which supplies some piquant *morceaux* that might be turned to useful account in an essay on the “Curiosities of Medical Evidence.” As this journal circulates chiefly, if not exclusively, among professional readers, it is quite unnecessary to occupy our space with an analysis of that portion of the evidence, given on the occasion, which has elicited the rather uncomplimentary strictures, contained in the subjoined extracts from the *Dublin Evening Mail*, the *Daily Express*, and the *Warder*; and indeed our non-medical contemporaries have hit the more prominent blots with a force and precision, which would leave little for us to add, were we inclined to go over the ground they have traversed. The truth is, the case is so clear and simple that it is thoroughly intelligible to any man of common sense and ordinary information; and the only thing puzzling in the whole transaction is, how any amount of perverse ingenuity could succeed in raising a haze of misty doubt respecting so plain a state of facts. But we have another and a conclusive reason for not examining the

evidence in detail. It is possible, we are informed, that the case may again become the subject matter of judicial inquiry; and we consequently feel bound to abstain from saying anything that might, by any contingency, influence the result one way or the other.

One observation we must, however, make, in order to guard ourselves from the imputation of negligently discharging our editorial functions. Dr. STOKES, it will be seen, deposed that an epidemic of spontaneous diffuse inflammation is now prevalent in Dublin, and that "the symptoms" of this epidemic are "a low form of fever, congestion of the lungs, and a special form of bronchitis, hæmorrhage from the nose!! and a tendency to the formation of purulent deposits in different parts of the body!!!" We shall not stop to point out that this description of the prevailing epidemic fitted the case almost as accurately as if the evidence had been expressly made for the case; but as our readers may naturally look to our columns for an account of so novel and strange an epidemic, alleged to be now prevalent in the city in which this journal is published, and as they may be induced to blame us for failing to supply them with any information respecting it, we think it right to state, as a simple matter of fact, that no such epidemic, as that so circumstantially described by Dr. STOKES, exists in this city. Erysipelas, indeed, has been, for some time, of very frequent occurrence in Dublin, but it presents no peculiar characters further than these, that it is complicated with angioleucitis more frequently than erysipelas commonly is, and that the accompanying angioleucitis has a greater tendency than usual to assume the suppurative form.

We now make room for the following extracts from the journals above mentioned:—

*(From the Evening Mail.)*

We abstained from any notice of the painful subject of the inquest on the body of Christopher McDermott, until we should be able to lay the case in full before our readers, which is done in our columns this evening. We have no doubt that every one will agree with us that the unfortunate event was a pure misadventure, and that as no shadow of ill intent can be cast upon Dr. Banks, so he will also be universally exonerated from all moral responsibility for the result, which his character warrants us in saying is deeply regretted by himself.

While we say this much, however, we feel it would be a dereliction of duty to avoid the occasion of offering our protest against the system of overloading investigations, under the name of medical evidence, upon the introduction of which a growing disposition has lately showed itself. It was plainly and satisfactorily proved by Dr. Geoghegan that the wound upon McDermott's scalp—a quarter of an inch long, about the sixth of an inch in breadth, and about an eighth of an inch in depth—in fact a pin-scratch—could not of itself have caused death, or even as much suffering as could reasonably be called inconvenience, and that the diffuse inflammation which proved fatal was a complication of the wound altogether accidental, and not at all to be expected as a consequence of so trifling an injury. This was the simple truth; and proved as it was by a competent witness, the truth was sufficient to secure for Dr. Banks the sympathy of every candid mind. We regret much, therefore, that any injudicious attempt should have been made to strengthen so good a case by "medical evidence," which was in fact a statement of the abstract opinion of a doctor who knew nothing whatsoever about the case, and whose general notions on some points were at direct variance with those of the other medical witnesses—as they seem to our unenlightened minds to be opposed to common sense. It is well known that when the form of inflammation which destroyed McDermott is epidemic, medical men will not willingly apply a leech or vaccinate a child, lest the slight wound made in either case should excite the latent plague. With this fact notorious to all, there was at least boldness shown in advancing the opinion, "that a person with a wound on his head, during the prevalence of the epidemic, would not be more predisposed to catch that epidemic than a person without any such wound."

*(From the Daily Express.)*

Coroners' inquests are in a fair way of running themselves down in Ireland. Within the last six months we have had several striking instances of their utter inutility, and worse than inutility—their tendency to pervert and obstruct justice. We shall merely name the Six-mile-bridge case to dismiss it. In that case the process of the inquiry was fair enough, and full enough; the extravagant absurdity of the verdict resting entirely with the jury. In the inquest on Mrs. Kirwan at Howth, the proceedings appear to have been what is called hugging-muggers. But the coroner's inquest on Monday last (13th instant), into the cause of the death of Christopher McDermott at the City of Dublin Hospital, affords a crowning proof of the incompetence of this tribunal, as at present constituted, for any other end than that of bringing such judicial investigations into public ridicule and contempt. The facts of the case under investigation, as admitted, are briefly these:—On the 29th of last month, Dr. Thomas Banks, a physician of high standing in this city, and, as we believe, an amiable and kind-hearted man, found the deceased, McDermott, who was a butcher's boy, committing a common act of nuisance in the lane close, by his house in Upper Merriem-street. The doctor, incensed, struck him with his cane, but the blow, although intended for the shoulder, fell on McDermott's head, inflicting such a wound that shortly afterwards, when the policeman came up, the blood that flowed from it covered the dress of the boy, and lay in great quantity on the street. The wound was dressed two or three times at the hospital, and McDermott getting worse, was admitted on the following Monday an intern patient, and died on Saturday last of erysipelatous inflammation of the neck, throat, and lungs. The question the jury had to determine was as to the cause of death, which, on this statement of facts, one would think was plain enough. Not so, however, the jury, or at least a portion of them. The evidence, indeed, on which they had to decide, contained much trash, the admission of which seems quite inexplicable. It affords a delicious illustration of what the wisdom of "eminent doctors" consists in, when we find individuals enjoying that distinctive appellation coming forward to depose on "general principles" as to what was or was not the cause of the poor boy's death. "Eminent medical men," physicians of great reputation, who had never seen McDermott either before or after his death, seemed well inclined to go as far as saying that the wound could not have caused his death; for it was with extreme reluctance one or two of them admitted the possibility of it. Cuvier, it is said, could, by merely examining a single fossil tooth, construct the entire skeleton of some gigantic antediluvian; but our Dublin medical celebrities can claim a rivalry in their own way with the great Frenchman, for by looking at the square inch of scalp containing the wound, cut from the head of the deceased, they undertook to say that the wound might not have caused the inflammatory disease that resulted in death. Wonderful sagacity! Pellucid and conclusive evidence! Among the absurdities of this medical evidence, we find it stated that, although there is at present an epidemic of an erysipelatous nature—that certain persons are more predisposed than others to this disease, among which butchers, as a class, are included—and that a person with a wound in the head would be more likely to be attacked with erysipelas than one with no wound, yet, in the opinion of those witnesses who gave their evidence on "general principles," the wound in McDermott's head had nothing to do with his death. It might have had, but they did not think it. Why? If we could ascertain the motive for producing such evidence at all, the answer might be found. The only medical evidence given worth a straw, and the only medical evidence that ought to have been admitted, was that of Dr. Geoghegan, the hospital physician who had charge of McDermott while a patient, and who made the post-mortem examination, and that of Mr. Webb, the resident pupil, who dressed the wound three or four times before the deceased entered the hospital. These gentlemen reasoned not on "abstract principles," but on a concrete case. They knew the particulars of it, and their evidence, fairly and honestly given, confirmed the conclusion which any person of common sense and impartiality knows is the true one—to wit, that McDermott died in consequence of the blow. An old "Joe," respecting a compatriot is familiar. He was charged with an act of felonious abstraction, which he, of course, denied. "I can bring two witnesses who saw you do it." "No matter for that (says Paddy); I can bring three who'll swear they didn't see me do it." In the same way, Dr. Geoghegan, who saw the cause, and

watched the effect, swears that the wound and the death were thus related. "What of that (cry Dr. Banks's friends)? here are three eminent medical men who saw neither one nor the other, and who swear that they don't think they were so related." The cases are precisely analogous; but we do not read that the jury acquitted Paddy Dr. Banks's—we mean McDermott's—jury could not agree. Did the medical evidence rob them of their common sense? The mode of conducting the inquest, we must say, was far from creditable. It was a blunder to admit such a mass of irrelevant and absurd evidence; but the evidence, such as it was, seemed to be given as much by one of the legal gentlemen present as by the witnesses themselves; so much so that one of the jurors thought it necessary to interpose his opinion that the coroner should take the words of the witnesses from their own lips, and not as they reached him, defective, if not perverted, through an interested channel. With respect to the verdict, it means nothing; and every one with whom we have spoken on the subject considers it a very lame and impotent conclusion indeed. The evidence as it stands is clear enough, but there is such a thing as men shutting their eyes wilfully to the truth where there is an object to be gained. The jury is described as "respectable." From a statement in a contemporary, it would seem that one or two of its "respectable" members volunteered to serve, not having been summoned. If we be not misinformed, a majority of the jury were anxious to give their verdict according to fact and common sense. Supposing this to be so, would it not be curious, and painful too, to find the "respectable volunteers" among the obtuse minority? The entire proceeding is one well calculated to confirm the popular impression that justice is not equally meted out to the rich as to the poor, and in that view we regret it extremely. Of Dr. Banks we can neither think nor speak with anything approaching to harshness. He does not deserve it. By an unfortunate occurrence which was little more than accidental, he has, however, caused the death of a poor boy; and as it did not accord with his own sense of truth and honour to stoop to any denial of having struck the blow, so it would have been better in every respect had the same feeling been as strong among those of his friends who showed so active an interest in his behalf at this inquest.

(From the *Warder*.)

We elsewhere publish a report of an inquest, held at the City of Dublin Hospital, on the body of a man named Christopher McDermott, and our readers will, doubtless, like ourselves, rise from the perusal of the medical evidence, given on that occasion, with a feeling of blank perplexity, mingled with an uncomfortable misgiving touching the uncertainty of medical science. The unlearned public, we apprehend, will be very apt to suspect, that grave and learned physicians, in the private exercise of their vocation, may very possibly act on opinions and principles as diametrically opposed, as those that were publicly elicited by the conflict of the medical testimony at the inquest in question; and such a suspicion, it is obvious, is anything but reassuring to the community at large. We shall not dwell upon the unfortunate occurrence which gave rise to the inquiry, further than to observe, that Dr. Banks must stand wholly acquitted, in the mind of every reasonable man, from a shadow of imputation upon his character. We do not take upon ourselves to decide between the contradictory medical evidence; but assuming that the trifling hurt, almost accidentally inflicted, was the cause of death, the fatal issue was clearly an exceptional result, most unlikely to follow so trivial an injury. But though we do not pretend to say which of the adverse medical opinions is the correct one, we know this much at all events, that Dr. Geoghegan's evidence entirely accords with the general popular belief. It is commonly thought that the existence of a wound very decidedly predisposes to an attack of bad inflammation whenever erysipelas is prevalent; and we ourselves happen to be aware of more than one instance in which surgeons of the greatest skill and experience have peremptorily declined to perform an operation which admitted of being postponed, or even to allow a person to be leeches or cupped, expressly on the grounds that any breach of the skin, however trifling, involved imminent risk of dangerous inflammation coming on. Such was the effect of Dr. Geoghegan's evidence; and we also find Mr. Cusack explicitly swearing that "a person wounded in the head is more likely to take erysipelas than a person who did not receive a wound." All this seems clear and positive enough; but suddenly our convictions are unsettled, and our confidence in medical science disturbed when Dr. Stokes stands forward and deposes that "a person with a wound on his head during the prevalence

of the epidemic, would not be more predisposed to catch the epidemic than a person without any such wound." It does not fall within our province, we repeat, to adjudicate between these discordant opinions; but we may just observe, that Dr. Stokes appears to have given his evidence much more loosely than accorded with the gravity of the occasion. For example, we observe that Dr. Stokes spoke of the "great probability of the erysipelas having been produced from a plug in the nose, placed there to stop bleeding," whereas it appears from the evidence that the erysipelas had appeared two days before the nostril was plugged. Now, really, if this kind of thing goes on—if, during a judicial investigation, new theories are started, with all the boldness of originality, contradicting the weighty evidence of such men as Dr. Geoghegan and Mr. Cusack, it must bring discredit upon the medical profession by weakening confidence in the certainty of the medical art. The medical profession must of course take care of itself; we can only tell its members what the public think. Such a conflict of testimony, upon a very elementary point, tends to raise the impression that medicine has no fixed principle, and scarcely any definitely ascertained facts. We have noticed this case because, irrespective of the judicial inquiry, it involves a matter of practical importance to the public. We gather from the evidence that a formidable description of epidemic is now prevalent. Are the public to believe, with Dr. Stokes, that a person may be leeches, bled, or have an operation performed upon him, without incurring any additional risk of contracting the dangerous epidemic disease; or are they to believe the direct contrary, upon the high authority of Dr. Geoghegan and Mr. Cusack?

#### A WORD TO THE FELLOWS OF THE COLLEGE OF SURGEONS OF IRELAND.

WE take some blame to ourselves for refraining too uniformly from allusion to the proceedings of the College of Surgeons; but the pressure of circumstances from which we could not well escape, has from time to time restrained us, and perhaps even deterred us from the performance of a duty which as public journalists we were bound to discharge. In this College alone, of all the medical institutions of the three kingdoms, the principle of self-government, either by the body at large, or its chosen representatives, has been in operation for a sufficient length of time to test its value; and its success remains to be proved, as regards the future only, for no doubt can be entertained as to the past. We do not mean to say that the results contemplated by the incorporation of the Surgeons of Ireland into a College, in 1784, have been realized to the extent that sanguine or enthusiastic men might have expected; but we venture to assert that the results have been at least as satisfactory as those which have flowed from less popular forms of organization. Of the vices, abuses, and evasions inseparable from corporation existence, it has of course displayed its share; but that a preponderating amount of valuable effects can be indicated as a consequence of its operations, there can be no doubt. But how is it to be now and hereafter? Nine years have elapsed since the popular constitution to which we allude was rendered still more popular by the grant of a Supplemental Charter, and the substitution of a representative executive government for that of the body at large, grown too cumbrous and unmanageable for the despatch of business. Have we now to discover that all this has proved a failure, and that the extension of the elective franchise to nearly five hundred Fellows was a mistake? We hope not, and therefore do we now offer a hint to those who entertain a similar hope. A trust has been reposed in the Fellows to elect a body of competent, independent, and honest men as an Executive Council with a President at its head, and that trust they should either fulfil or abandon. It has not been granted to be exercised as a mere trivial privilege, but to be discharged conscientiously, and with due

regard to the "reputation, honour, and dignity" of the College, and to the welfare, not only of its Fellows and Licentiates, but of the Surgical Profession at large. To come, however, to the point: our object in this brief allusion is to warn those whom it may concern resolutely to refuse to commit themselves by promise to any particular course, on the occasion of electing Presidents and Council next year. For ourselves, we are free to say that any attempt to extort so premature a pledge to vote for any particular candidate or candidates should be treated as a piece of very great impertinence; and we do hope and believe that every man who cherishes the feelings of a gentleman will entertain the same opinion. Indeed, we would fain persuade ourselves that past experience will induce the Fellows to discountenance the practice of canvassing for places in the Council or the Presidential chairs; for although it cannot be prevented, it must be admitted that it is often a most disagreeable infliction, and sometimes an exceedingly offensive one. At the present moment, the Council is, we understand, engaged in the reconsideration of the Charter and By-laws, with a view to the adoption of improvements and the removal of some grievous abuses which have crept into the educational system. At this, it seems, certain persons have taken alarm, and in order to defeat any attempt to effect such an object, have commenced an agitation and canvass. This is of course as much to intimidate the Council as to secure the election of those who may suit their purposes; but we thought it only right to let such Fellows of the College as consult its interests know that such tactics are in course of concoction. We have also to warn them against giving credit to statements which may be made to them respecting these matters until they institute inquiries as to their truth. Surely no great mischief can result from gentlemen suspending their opinions, and refraining from committing themselves, until the proper season shall arrive. We have reason for believing that then a gentleman of unsullied character and acknowledged independence will be put in nomination for the Vice-Presidency, and then it is that the Fellows will have to decide both on this and other matters equally important.

### THE CONVICT KIRWAN.

We find that a London medical journal (the *Lancet*) announces an intention of making the case of this unfortunate man the subject of discussion in its columns. If this is to be done with a view to obtain a commutation of punishment no one should object; but the course is a perilous one for the convict. Be this, however, as it may, it is obvious that no notice can be taken of any observations on the subject by us until the period arrives for its free discussion.

### LOCK HOSPITALS.

Amongst the measures for the regeneration of Ireland, and for serving the triumph of sound principles of political economy, as well as for the promotion of Sanitary Reform, rival Statesmen have hit upon the notable scheme of suppressing the Lock Hospital in Dublin, and trusting to free trade for the extirpation of the venereal disease. Philosophic philanthropists will rejoice to contemplate the happy results of the plan elsewhere:—

I reside in a manufacturing district, and am the medical officer of the union workhouse. In my private as well as public capacity, I have good reason to know that venereal diseases are now existing to an extent barely credible; and that it is not alone in the town in which I reside that such is

the case. Lately, when examining recruits for the militia, I found them to be diseased to the extent of twenty-five per cent. Surely it is time that public attention should be called to such a state of things, if we have any regard for the coming generation; and that, by some wise regulation, means should be taken to keep in check a scourge well known to "visit the sins of the father upon the children unto the third and fourth generation."—*Letter in Lancet.*

I think the subject of the following letter deserves the attentive consideration of those who have the will and the power to benefit the condition of our soldiers and sailors. I allude to the propriety of establishing Lock hospitals at our great naval ports, for that unfortunate class of females, who are the means of propagating a disease fearful in its consequences, and without doubt a very powerful cause of sapping the foundations of our nation's strength. The annual expense incurred in the treatment of syphilitic cases at our military and naval hospitals, is enormous; and even on the ground of economy, the subject is worthy of the attention of government. I understand that the physicians and surgeons of our naval hospitals have repeatedly recommended to the admiralty the propriety of adopting the plan now suggested. It has also been proposed, that the old custom of charging a certain sum from all patients admitted with the disease in question should be revived. This deduction might have a salutary effect on some of those on whom the voice of conscience, and the restraints of morality and religion, fall unheeded. While human nature remains as it is, all men cannot be arrested in their career of vice. It is clearly, therefore, the duty of the philanthropist to endeavour to mitigate an evil which he well knows cannot be entirely removed.—*Id.*

### TO CORRESPONDENTS.

We have received Dr. McCormack's book on "Sanitary Reform" and Mr. Ellis's "Introductory Lecture" (both *ad rem* and well timed), and propose to notice them in our next. An "Indignant Spectator" will perceive that we have adopted his suggestion. The gentlemen shall be undeceived. The removal of the Physician of the Cork Foundling Hospital is under consideration, and shall be noticed in our next. We find in the *Westmeath Independent* Lord Castlemaine's reply to the MEDICAL PRESS, which has amused us not a little, and may amuse our readers next week.

### MEDICAL BENEVOLENT FUND OF IRELAND.

Dr. J. F. DUNCAN, Treasurer, thankfully acknowledges the receipt of the following sums since last report:—

Dr. Andrew Nolan, Wicklow, ...	£1	1	0
Dr. Wm. O'B. Adams, Kingstown, ...	1	1	0
R. Burnett, Esq., Tullow, ...	1	0	0
Dr. Bird, Banagher, ...	1	1	0

As the current year is now approaching its close, country subscribers who have not yet paid up their subscriptions for 1852, are respectfully requested to do so at their earliest convenience; and the collector, Mr. James Black, has been directed to call upon those resident in Dublin for the same purpose.—19, Gardiner's-place, December 20, 1852.

### SYPHILITIC DISEASES:

Their Pathology, Diagnosis, and Treatment, including Experimental Researches on Inoculation, as a Differential Agent in Testing the Character of these Affections.

By JOHN C. EGAN, M.D., M.R.I.A.,

Fellow and Licentiate of the Royal College of Surgeons in Ireland; Member of Council of the Surgical Society of Ireland; formerly Surgeon to the Westmorland Lock Hospital, &c. &c.

London: John Churchill, Princes-street, Soho.

Dublin: Fannin and Co., Grafton-street.

### NEWSPAPER FOR THE FARMING AND GARDENING INTEREST.

January 1, will be published, price Sixpence, free by post, each volume complete in itself,

*Enlarged to twenty-four folio pages,*

The First Number for 1853, of the

### GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE;

A Weekly Record of Rural Economy and General News.

*The Horticultural Part Edited by Professor Lindley.*

*The Farming Part (under the Editorship of a Practical Farmer) treats of—*

<p>The Practice of Agriculture, Agricultural Science, Animal and Vegetable Physiology, Improvements in Implements, described by Woodcuts whenever requisite, Better modes of Husbandry, Results of Experimental Farming, Growth and Rotation of Crops,</p>	<p>Management of Stock, Veterinary Science, Drainage, Irrigation, Forestry, Road-making, Farm-buildings, Labourers, Treatment of Poultry, Agricultural Publications.</p>
--	--

In short, whatever affects the beneficial employment of Capital in Land.

Reports are regularly given of the English, Scotch, and Irish Agricultural Societies and Farmers' Clubs—London Market Prices of Corn, Hay, Cattle, Seeds, Hops, Potatoes, Wool, Coal, Timber, Bark, &c., and the Weekly Averages.

As regards the Gardening Part (under the Editorship of Dr. Lindley), the principle is to make it a weekly record of everything that bears upon Horticulture, Floriculture, Arboriculture, or Garden Botany, and such Natural History as has a relation to Gardening, with Notices and Criticisms of all works on such subjects. Connected with this part are

*Weekly Calendars of Gardening Operations,*

Given in detail, and adapted to the objects of persons in every station of life; so that the cottager with a few rods of ground before his door, the amateur who has only a greenhouse, and the manager of extensive gardens, are alike informed of the routine of operations which the varying seasons render necessary. It moreover contains Reports of Horticultural Exhibitions and Proceedings—Notices of Novelties and Improvements—in fact, everything that can tend to advance the profession, benefit the condition of the workman, or conduce to the pleasure of his employer; Woodcuts are given whenever the matter treated of requires that mode of illustration.

Replies to Questions connected with the object of the Paper are also furnished weekly.

Lastly, that description of Domestic and Political News is introduced which is usually found in a Weekly Newspaper. It is unnecessary to dwell on this head further than to say, that the Proprietors do not range themselves under the banners of any Party; their earnest endeavours are to make the *Gardeners' Chronicle and Agricultural Gazette* a full and comprehensive record of facts only—a Newspaper in the true sense of the word—leaving the reader to form his own opinions: their object being the elucidation of the Laws of Nature, not of Man. The reader is thus furnished, in addition to the peculiar features of the Journal, with such information concerning the events of the day, as supersedes the necessity of his providing himself with any other weekly paper.

A Prospectus, with List of Contributors, may be had on application, or by letter, at the Office, 5, Upper Wellington-street, Covent Garden, London.

Parties intending to commence with the New Volume had better give their orders at once to any News-vender.

### TO SURGEONS, DISPENSING CHEMISTS, ETC.

SULPHATE of QUININE, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, cap-suled, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

*Superior Dissecting Instruments well worth the inspection of the Student.*

### THE COMPOUNDING DEPARTMENT AT

#### G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

 Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

### SHIRTS CUT BY MACHINERY.

#### WEBB AND CO.'S

New System of Shirt-cutting by Machinery enables them to produce really First-class Shirts at prices lower than they have ever yet been offered.

Their Eglinton Shirts,

at 2s. 6d., 3s. 6d., and 4s. 6d. each,

are accurately Cut, elegant in Design, and perfectly sound in Fabric.

 A large assortment of Fancy Veined Full-dress Shirts always on hand.

### THE TAILORING AND GENERAL OUTFITTING WAREHOUSES

are now most extensively supplied with every description of WINTER CLOTHING.

### THE READY-MADE DEPARTMENT

contains an immense variety of

Top Coats, Travelling Coats, Wrapper Coats, Pilot and Frieze Pea Coats,

at 15s., 17s. 6d., and 20s. each,

which, for Workmanship and Solid Value, are not and cannot be surpassed.

WEBB AND CO.,

10, 11, and 12, CORN-MARKET.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. Wednesday, December 22, 1852.

### SOME PATHOLOGICAL REMARKS ON CHRONIC ENLARGEMENT AND INDURATION OF THE TONSILS.

By STEPHEN O'RYAN, M.D.,

Member of the Surgical Society, Physician to the Tralee Dispensary, &c. &c.

THIS affection being exceedingly frequent among the poorer population of the city of Dublin, is consequently not undeserving of the attention of medical practitioners, on another account it demands our especial consideration: viz., that it is not, as often supposed, a trifling local affection; but on the contrary, in the greater number of cases, a local manifestation of serious constitutional taint.

The characters of this affection are too well known to require any description from me. I shall only observe, that it may occupy one or both tonsils; both these glandular organs generally and mostly undergo this change at the same time. Like other chronic diseases, it is often the sequel and result of acute inflammation. But we cannot always discover a chain of causes and effects to guide us in the history of its pathology, for it occurs sometimes in connexion with inflammation of extremely low character—an inflammation which the older pathologists would have termed "cold." Sometimes, too, it steals on in a manner altogether imperceptible, acquires considerable volume, and still remains unknown to the patient and physician, until an inspection of the fauces reveals its existence. Many a time have I been astonished to find the isthmus faucium almost closed by the encroachment of double enlarged tonsil, and yet the patient suffered little or no difficulty of deglutition or inspiration.

In some cases, and these not infrequent ones, the converse of this condition of parts has presented and occasioned me no inconsiderable surprise. I mean a difficult inspiration and painful deglutition occurring with inconsiderable enlargement of the tonsils. This condition admits, however, of explanation; for in the cases in which it presented, I think that I have generally been able to ascertain the

coexistence of ulcers or abscesses on the tonsils, or in the pharynx, or of an erythematous inflammation extending along the latter organ, or of some laryngeal, bronchic, or pneumonic affection. I have also observed that prolongation of the uvula, whether occurring alone or in conjunction with enlarged or indurated tonsils, occasions in all cases more or less of the distress alluded to.

The induration of enlarged tonsils exists sometimes to a very striking degree; this condition would lead us, even without the aid of necroscopical inspection, to infer the effusion of plastic lymph into the cells of the diseased organs. The hypertrophy thence resulting is further aggravated by the obstruction which ensues to the excretion of the products of the muciparous glands. Interstitial hypertrophy and glandular obstruction obtain together. Hence, keeping this pathological state in view, we shall be prepared for the obstinacy with which enlarged tonsil will often, very often, persist in spite of the most judicious treatment.

At the commencement of these remarks, I stated that enlarged and indurated tonsil, with or without accompanying ulceration or abscess, is generally to be viewed as a local manifestation of a constitutional taint.

I shall now proceed to enumerate, in the order of their occurrence, the diseases with which I have found this affection connected:—

1st. Struma in some one of its protean forms.  
2nd. Syphilis of some standing. Patients have usually laboured under it for a certain period, and have undergone incomplete or improper treatment.  
3rd. Mercurio-syphilis, or the cachexia, presenting in persons who have taken mercury irregularly for syphilitic disorders.

4th. Bronchitis of the chronic type.

5th. Amenorrhœa in young females. This mostly functional disorder is, it is known, very prevalent in all large communities. In Dublin it is extremely common among the working classes or tradespeople, especially the milliners, and I have very often seen it present this local manifestation of enlarged and indurated tonsils.

When giving expression to the foregoing ideas on the pathology of enlarged and indurated tonsil, I do not lose sight of the many other diseases referrible to the digestive apparatus, the respiratory system, &c. &c., which often give origin to this glandular affection. Neither do I pretend to assume that it is in every case to be investigated as a constitutional malady; on the contrary, I am most willing to believe and admit that it is occasionally a purely local change, having no connexion with constitutional influences. But I consider, and cannot shrink from expressing my belief, founded on pretty numerous observations, that such cases are very rare.

The observations which I have presumed to present to the Surgical Society, are evidently of more than mere pathological interest; for they point to the rational and scientific method of treatment, and these may serve as guides to the judicious practitioner, who will be always anxious to fulfil the well-known precept of "*cito tuto et jucunde*."

Of the details of treatment, it would be superfluous for me to make mention. Every practitioner is aware of the extremely obstinate character of some of those indurated amygdalæ, and how for months, or even years, they resist every therapeutic agent. A very modern agent, the "liquid nitrate of mercury," has been introduced into the class of caustics, and though not prepared with any cases to support the practice, yet I venture to propose a trial of it in rebellious cases.

This active salt has been frequently employed with success as a topical application in another affection, the hypertrophy with or without ulceration of the os tincæ, and with more than local effects, for it has been absorbed, and produced beneficial results throughout the general constitution.

It has occurred to me, that a topical remedy of a nature to be absorbed, might be found to occasion a healthy change in many of those hypertrophied tonsils.

Another reason induces me to propose the application of the "liquid nitrate of mercury"—namely, that when all other remedies have failed, our last resource (excision of the diseased tonsils) is frequently objected to, especially in private practice. Excision is, moreover, an operation not without its dangers, and consequently should, in scientific surgery, be eschewed as much as possible.

The PRESIDENT observed, that the Society would be happy to hear any remarks of a practical nature, from surgeons present, having reference, on the one hand, to cases where the removal of the enlarged tonsils by the knife might be judiciously adopted; and on the other, to cases where it could not be resorted to with equal prudence and safety. It would also be interesting to learn the results of the various topical applications employed in the treatment of these affections.

MR. TUFNELL stated that a case had been reported in a medical journal, about a year since, in which the death of the patient was attributed to the application of the acid nitrate of mercury to the fauces, causing spasm of the glottis. In cases of enlargement of the tonsils, depending on struma, he found that a cure might be effected by the application of powdered burnt alum, three or four times a day, with the point of the finger, and persisted in for a considerable period of time. It was worthy of remark, that in many of these cases, the complaint came on in the winter, and departed of its own accord with the approach of summer; and having seen a considerable number of them relieved by the habitual use of alum, he would strongly recommend a trial of the latter, before they resorted to the use of the acid nitrate of mercury, which had, in one case at least, given rise to fatal consequences.

DR. EGAN remarked that the acid nitrate of mercury had been employed in many cases, at the Lock Hospital, by himself and his late colleague, Dr. Byrne, without producing any prejudicial results whatever.

DR. HENRY KENNEDY said he would expect more benefit from a constitutional than from a local plan of treatment, and if he were to choose one remedy in preference to another, his choice would fall upon the cod-liver oil. He did not say that he would depend on it alone; but if he was confined to one agent, he would regard cod-liver oil as in-

initely the best that could be employed for the purpose. The writer of the paper before the Society seemed to think that the difficulty of swallowing was attributable to the swelling of the affected parts. Now, he (Dr. K.) had met with cases, where there was considerable swelling, and but a slight amount of difficulty in swallowing; and on the other hand, he had seen cases, where there was a great deal of difficulty in swallowing, and but a trifling degree of swelling. He was inclined to explain this fact by the temperament of the patient. Some ulcers would, no doubt, always produce difficulty of swallowing, but in many other cases, no such symptom was experienced, and he was strongly of opinion, that the difficulty of deglutition must be attributed rather to constitutional causes than to the peculiar condition of the parts themselves.

DR. BEATTY wished to refer to a mode of practice which he had employed for many years with, he might almost say, universal success, in the removal of these obnoxious swellings. In many cases the patients objected to have them removed by an operation. The parents of young persons very often dreaded the use of the knife, and when they did so, another proceeding might be adopted with every prospect of a successful result—namely, the direct application of powdered nitrate of silver to the enlarged tonsils. It could be applied with a large camel's-hair pencil, slightly damped, and with the hairs bent a little towards the point. The side of the pencil should be pressed on a quantity of powdered nitrate of silver, spread out upon a piece of paper, so that a considerable amount of it might be taken up by the brush, and the latter was then to be pushed in, and kept in contact with the tonsil for a brief period of time, and afterwards withdrawn with the greatest care. The application was to be repeated every four or five days, so as to allow the eschar, produced by the nitrate of silver, to have time to come away; and if the disease was persecuted (that was the only term he could employ to convey his meaning) in this way, for a considerable period, and suitable constitutional remedies adopted at the same time, they might confidently expect that a cure would be accomplished.

DR. JACOB would be glad to know whether any gentleman present could furnish them with his experience as to the use of the actual cautery in cases of this kind? He asked this question, because he remembered hearing that Scarpa had cured the celebrated Catalani by passing a red hot wire through the affected tonsils.

DR. BENSON requested to be informed how long Dr. Beatty's treatment had to be continued before the cure was effected?

DR. BEATTY—A little more than two months.

DR. BENSON said he would certainly join Dr. H. Kennedy in saying that the cod-liver oil was extremely valuable in this class of cases, and he could also speak in very favourable terms of the use of the syrup of the iodide of iron. In general, however, these cases, it was pleasant to know, would get well after the period of puberty, no matter what line of treatment might be adopted; but until then, relapses were almost sure to occur whenever the patient caught cold, especially in damp weather.

DR. BENSON said he had a very short but interesting communication from a distinguished member of the Society.—Dr. John Wilkinson, Surgeon to the County Limerick Infirmary. It related to the extraction of a foreign body from the knee-joint, and the author had enclosed the body for the inspection of the Society:—

#### CASE OF SUCCESSFUL REMOVAL OF A FOREIGN BODY FROM THE KNEE-JOINT.

By JOHN WILKINSON, M.D.,

Surgeon to the County Limerick Infirmary.

The enclosed I removed from the right knee-joint of a young man, aged 21, now in the County Limerick Infirmary. It is three weeks since the operation, and he is now quite well, walking about his ward. About sixteen days before his admission, he fell suddenly lame, and then, for the first time, felt something move about in the joint; he could move it from below up or from the out to the in-

side of the joint. It gave him great pain when pressed on, particularly when placed at the outside. It was removed by the subcutaneous section. It was moveable and very difficult to fix in any one place, and was constantly slipping away from the point of the bistoury. At last I got one of my colleagues to press with his thumbs against it, and keep it fixed at the outer and lower part of the joint, near the head of the fibula, and made an incision in the integuments about one inch from the foreign body. I found great difficulty in opening the capsular ligament with the small point of a bistoury, and had to withdraw it and introduce a small scalpel with a narrow blade, when I at once succeeded, and the foreign body slipped out of the joint under the integuments. It was my intention to have left it there till the wound in the capsular ligament and integuments were healed, but finding that the knife had made an opening in the integument so large as to admit its exit, I thought the risk of letting it remain as great as if it was let out, so by very little pressure it shot out through the external wound. When removed it was about one-third larger than at present. About three days after the operation, he got erysipelas, extending down the outside of that leg, attended with a good deal of fever and pain in the wound. After a few days an abscess formed at the wound, which was opened, and all went on well after.

Some years ago, I had a similar case, which did well without a bad symptom. But the foreign body was not removed under the integuments for some days after it had been let out of the joint.

Dr. JACOB said it was worthy of remark that a part of the specimen had acquired a sort of ivory polish.

Dr. BENSON observed, that it resembled a miniature palette, having one of its surfaces smooth and the other rough.

Dr. GEOGHEGAN said that, some years ago, he saw a case, where a foreign body was removed by an operation from the knee-joint of a healthy-looking young man, which was followed by inflammation and suppuration of the joint, of so violent a character that amputation had to be resorted to, though without success, as the patient ultimately sank and died. The unfortunate result in this case might be attributed to the fact that due attention was not paid to performing the operation in the proper way, as described by Mr. Liston and others, who have written more recently on the subject.

Mr. BUTCHER observed, that the point just referred to by Dr. Geoghegan was one of much practical importance to the surgeon, and should not be passed by without an observation or two upon those cases which had turned out in a satisfactory manner. When the function of the limb was impeded, and the patient was unable to follow his ordinary avocations, it certainly would be the surgeon's duty to attempt the removal of these foreign bodies; but then it must be kept in mind, that in some instances they would escape altogether, not only the examination of the patient, but the closest attention of the surgeon himself. In the latter part of last winter a case of this kind came under his observation. A young man, aged about 19, had been in hospital for a length of time with a foreign body in his knee-joint, from which he experienced a great deal of suffering, and was prevented from attending to his ordinary business. His object in coming to him was to have the foreign body removed from the joint; and on making an examination, he found that it was moveable and could be passed from one side of the joint to the other by manipulation with the fingers. At the patient's request, he agreed to perform the operation, not according to Gensoul's method, but according to the improved plan recommended by Liston, who had contributed to the *Dublin Quarterly Journal* two cases, in which the same operation had terminated successfully; and if the same method had been pursued in the case mentioned by Dr. Geoghegan, it probably might not have resulted in the amputation of the limb. He thought that surgeons ought not to extract these foreign bodies in all cases, without discrimination, but only where there appeared to be an urgent reason or necessity for doing so; and if it must be done, he was of opinion that Liston's plan was the best that could be adopted.

## ADDRESS

DELIVERED AT THE OPENING MEETING OF THE  
DUBLIN STUDENTS' MEDICO-CHIRURGICAL  
SOCIETY.

By MR. ARTHUR H. TAYLOR,  
Clinical Clerk, City of Dublin Hospital.

GENTLEMEN,—It is with mingled feelings of pleasure and regret that I this evening find myself called upon by the wishes and exigencies of the Society (though not the person upon whom this duty should have properly devolved) to open the proceedings for the present session by the usual introductory address—pleasure, I must feel, that such an honourable though responsible office should have fallen to my lot, but this feeling is nearly counteracted by that of regret, the interests of the Society being my first thought—regret, that the brief period left for consideration should have deprived the committee of the opportunity of selecting some one of my more senior fellow-students who might have more efficiently and more eloquently discharged the duties appointed me. I trust, therefore, you will bear with me whilst, driven by the impulse of necessity, I briefly endeavour to lay before you the objects of this Society and the views with which it was originally established, together with a cursory glance at what has been accomplished by it during the past session, and its prospects for the present one.

This Society was founded for mutual instruction and the advancement of that great principle of medical and surgical science—observation; more particularly as applied to clinical study, that grand basis upon which it has been elevated to its present exalted position, and on which it must depend for its future advancement—an advancement to which the discoveries of Harvey, Hunter, Laennec, and a host of other illustrious men have contributed so much in their several departments, and to which the many improvements in physiology and chemistry, aided by the great advances made in necroscopic and microscopic research, have already added, and are still likely to add, in every department of medical science. Thus the study of our profession in the present age affords advantages to the student not enjoyed by our predecessors; formerly it was pursued through a difficult and uncertain course, and though now apparently more complicated, it is in reality much simplified, one science aiding and assisting the advancement of the other; and this may be best illustrated by comparing it to an elaborate system of levers, by which a given resistance is overcome at a comparatively small expenditure of power: physiology assisting in regulating the diagnosis and treatment of disease, these again being eminently advanced in their turn by microscopic science. The study of morbid anatomy is naturally elucidated in an increased degree by physiological improvement, and the assistance medical science has derived from chemistry is very great indeed, yet all these are but different means, acting separately or in combination, for the attainment of the same grand end—observation.

It is at the bedside of the patient that the physician, as well as the student must look for information—there, must both acquire practical knowledge of those theoretical principles on which their science is founded—there alone, can the inexperienced student, under the guidance of the former, hope to acquire fixed and definite views of disease and the art of diagnosis, and in no way can these important objects be more beneficially accomplished than by the careful and systematic noting of hospital cases, and the reading of such reports before this Society, where oversights and real or apparent discrepancies are almost certain to meet with discovery. This it must be evident, even to the most prejudiced, must lead to real and solid improvement, both directly and indirectly—directly, as regards the increased attention bestowed on the case in hospital, whilst at home we are led, by the prospect of well-regulated discussion here, more particularly to study the different symptoms and the modes of treatment which have been adopted for their relief—indirectly, such reports must be a source

of improvement to all of us, as the reading of notes of even the most simple malady, and the discussion thereon, often serves to elicit facts either novel or entirely unknown to us before. Let it not, however, be supposed that observation is to be confined to the mere reporting of facts, this would be of little or no value unless directed by study and reflection; "for," says a French writer on this subject, "to observe Nature is not enough; she must be interrogated if we wish to wrest her secrets from her, and at the same time acquire the means of communicating to others the result of our researches."

How surely does example elucidate precept—a simple fact, a glance, a single word, frequently serving as the connecting link between ideas before scattered and undetermined, binding them together, and strengthening them into fixed principles for our guidance; and thus it is in our clinical studies, often we find that particular cases and the simplest facts as described in books, convey to our minds but a confused or erroneous idea of the subject, no matter how carefully soever we may have studied and weighed the import of every word; then present such a case to our observation in hospital for the first time, and the chances are, that at a single glance the difficulty disappears, conveying to the mind that most pleasant sensation which we all feel on suddenly overcoming any mental difficulty; or this may be compared, if things intellectual may find comparison in things mechanical, to that beautiful invention of Daguerre, in which the arrangements lie dormant till in a moment light is admitted, and a perfect picture is the result. Observation sheds her rays on the hidden camera of the mind, and a perfect idea is formed—both equally transient till rendered permanent, each by its proper agent: all ideas being impressed on the tablets of the mind by the after-process of reflection.

No doubt clinical observation may be attended to without noting a single case, but not so perfectly nor with such permanent advantage to ourselves, whilst at the same time we lose the opportunity of acquiring experience in the description and conveyance to others of our ideas of particular cases—an experience which our lot in after-life may call upon us to employ. That this is of importance all must admit; but in order to draw up correct reports of cases, it is not sufficient merely to observe the phenomena of their progress, this must be done accurately; and to do this the observer must possess many requisites both of fact and discernment, together with a correct knowledge of the value of words and the precise meaning which they are intended to convey, with a well-regulated system of arranging the facts as observed; for a statement of a case should not consist of a mere random detail of such symptoms as accident has caused to be observed, nor yet of a confused or superfluous enumeration of them. The symptoms should be arranged so as to show their relation to each other and their bearing on derangement of a particular function or organ, that thus they may lead to a correct diagnosis. This knowledge is only to be obtained by practice, and though advised by some of our highest authorities, I have heard persons declare it to be a "useless waste of time." In answer to such, I can only say, heed them not, exert that self-reliance and self-confidence on which hereafter in moments of peril may be your only dependence. Regulated by a becoming modesty, I would say, let us think and judge each one for himself; note, and carefully note, your hospital cases, and by so doing lay up a well-founded stock of experience—an experience which time can only increase, and which is only to be acquired whilst we are students and in the wards of our various hospitals. Let us, then, take for our motto the following axiom of an ancient author, which says, "Ars medica est tota in observationibus,"—a saying which is equally applicable to the study of morbid anatomy, to which, for the precision and accuracy now attained in the diagnosis of disease, we are mainly indebted. This study is of the utmost importance and from the many advantages derived from necroscopic science, we should not be deterred from it by a few moments of trouble or disgust; for when we have followed a case from its commencement to its termination,

we shall be amply rewarded by finding the diagnosis to have been correct, or the satisfaction of having an opportunity of altering it if erroneous; but to derive all the advantages which it is capable of affording, we should divest ourselves of all preconceived ideas, and be guided only by a desire of unfolding the truth.

I am afraid I have already trespassed too largely on your patience, but trust you will pardon me whilst I explain that, although hospital reports are preferred, do not misunderstand me, or for a moment imagine that original papers, connected either directly or collaterally with the study of our profession, shall be less favourably accepted; on the contrary, they shall at all times be received with pleasure, and meet with the most friendly consideration.

I shall now briefly enter into some short details of what has been done during the past session. At the opening meeting last year, it was stated that the Society then consisted of about thirty-seven members, and the hope was expressed that the list would rapidly increase; this was speedily responded to, and before long our numbers had increased to upwards of fifty. During the course of the session a number of very interesting communications were read before the Society—about twenty-eight papers in all—the particulars of which are to be seen in the minute books of the Society. Most of these led to much discussion, of a friendly and instructive character, on various points of practice, diagnosis, &c.; often elucidated by the kind interference of some of the medical gentlemen generally present; and though such was not strictly in accordance with the rules of the Society—a fact of which they were ignorant—we cannot but feel grateful to those gentlemen for the friendly feelings which prompted them to do so.

The prospects of the Society for the ensuing session are most promising. The list of members is about the same as last year, and amongst them may be found gentlemen from nearly every school and hospital in Dublin. Its advantages are, I think, becoming more generally understood; and there can now be little doubt but that it will meet with a continuance of that support which gave it birth, and which is absolutely necessary for its well-being and future success.

It would be an act of injustice on my part were I to omit mentioning the universal approbation and kind offers of assistance and support which the efforts of this Society have met with from the first men in the profession in Dublin; and I think I cannot better conclude my rather tedious and imperfect remarks than by offering my own heartfelt thanks and those of the Society to the medical profession in general, and to those gentlemen in particular who, by honouring us with their presence here this evening, have shown that they do not think our efforts for our own and fellow-students improvement is a matter of too trivial importance to merit their countenance or support.

#### ORIGINAL COMMUNICATIONS.

#### SULPHURIC ACID IN DYSENTERY.

By GEORGE ELLIS, M.D.

SEVERAL months have elapsed since the attention of the profession was first prominently called, in the pages of the *Lancet*, to the treatment of passive diarrhoea and cholera by sulphuric acid. The same remedy has lately been recommended even in acute dysentery, but few, probably, of our practitioners here would venture to employ it in the severer forms of this complaint, to which all our preconceived notions of the medicinal action of this acid would pronounce it inapplicable and likely to be hurtful. The following case, therefore, which occurred a day or two since, may, perhaps, interest some of your readers.

My patient, a college student, aged about 24, slight and delicate looking, of regular habits, was attacked, on the morning of Friday, December 10th, with diarrhoea. He walked some distance, in the course of the day, to attend an engagement at college, where he was seized with a shivering fit, and returning home sat over the fire all the evening. Took mutton-broth at dinner, to which he at-

tributes the great aggravation of the diarrhoea which soon after followed. The discharges, now attended with pain, were so frequent, during the night, as totally to prevent sleep. On Saturday evening, having had no relief, he obtained some medicine in the neighbourhood. From this time until the Monday following, when I first saw him, he suffered extremely; in his own words, "he never suffered so much in all his life before, and had no sleep or rest whatever."

Monday, December 13th, one o'clock p.m.: Has had about twelve very scanty motions within the last hour, attended with excessive pain and tenesmus, and consisting almost entirely of blood. The evacuations of the past night were, as the attendant informs me, of the same character. Abdomen is full, tense, and tympanitic, with much tenderness on pressure; tongue is covered with a thick whitish fur; complains of thirst; pulse about 90, weak. The medicine on the table is evidently *mist. cretæ c. tinct. catechu*. There is also a box of pills, one to be taken every hour. He has taken several doses of the mixture. Of the pills he has taken but four. Last dose of mixture was rejected, and he has now, when getting up to stool, severe retching, with great prostration, but without actual vomiting; no cramps; complains most of pain and tenesmus, increased, he says, by the medicine.

I was about to pursue, at once, the more orthodox treatment of calomel and opium, but as my patient had, for some time before this attack, shown symptoms of constitutional delicacy, and had recently lost relatives from phthisis, I apprehended the effects of a tedious illness and convalescence; and, as among the numerous notices which I had read of the sulphuric acid treatment, and even in the reports of its opponents, I had not seen any cases mentioned in which serious consequences had resulted from its use, I determined to make a cautious trial, and prescribed the following mixture:—

℞ Acid. sulph. dil. ℥ii.  
Mist. camphoræ, ℥v.  
Tinct. cardamom. c. 3ss.  
Syrupi, ℥ss. M. st. ℥i. omni hora.

A large poultice to abdomen; drinks to be taken cold and in small quantities.

Half-past three p.m.: Took the first dose at half-past one, and was about taking the third when I returned. Motions scarcely less frequent, but attended with decidedly less pain; stools still bloody and scanty, but contain a slight tinge of dark brown-coloured matter; pulse 84, fuller, but softer. The state of the abdomen is remarkable; the fulness and painful tension are gone; he can bear pressure without wincing. Another dose of the mixture was now given, with directions to continue it at intervals of two or three hours.

14th, half-past ten a.m.: Reports himself much better; has taken but three doses since my last visit; motions still frequent, but pain nearly gone; blood has disappeared; fæces still liquid, but more copious, and of dark brown colour; tongue cleaning at anterior part and sides; thick fur appears as if partially peeled off. Continue the mixture *tertius horis*.

Seven p.m.: Has had eight motions since last visit, but with scarcely any pain; complains of a sinking sensation in stomach after taking the mixture.

Chicken broth, statim, with bread.  
Add. *misturæ mist. camph. ℥ii. et syrapi ℥ss.*  
Capiat 3ss. post singulas dejectiones.

15th, eleven a.m.: Took the mixture after each motion till midnight, when he had a solid stool, and soon after fell asleep; slept soundly the whole night, and awoke greatly refreshed; has had no motion since twelve last night; has no pain whatever; tongue cleaning rapidly. Continue chicken-broth, and medicine if necessary.

16th, eleven a.m.: Took but two doses within the last twenty-four hours; motions solid and natural; tongue clean; pulse 72, soft. Convalescent.

The rapidity and completeness of this patient's recovery struck me as presenting a pleasing contrast to the usual

course of such cases, and as warranting some confidence in the remedy used. The *mist. camph.* and *tinct. cardam.* had probably much effect in removing the painful flatulence, and the sulphuric acid in altering, in some way, the morbid condition of the mucous surfaces, as shown by the tongue. From a single instance, however, no satisfactory conclusion can well be drawn. I abstain, therefore, from further remarks, only adding that the subject of the above treatment has been perfectly well since in every respect, eating and drinking as usual, and starts to-morrow on a long and fatiguing journey.

Leeson-street, December 20, 1852.

## SEVERE COLD AS A LOCAL ANÆSTHETIC.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—In the *MEDICAL PRESS* of the 8th inst., there are two references in different articles to cold as an anæsthetic, which, with your permission, I would be happy to make some observations upon.—I am, sir, your most obedient servant,

JAMES ARNOTT, M.D.

London, 16, Upper Gloucester-place,  
December 15, 1852.

Professor Mütter's principal purpose being to vindicate the American exclusive claim to the discovery of etherization (a claim which I was not before aware had been disputed), and to extol the importance of the invention, it could hardly be expected that its rival, congelation—its rival at least on certain occasions—would be placed in the most favourable light. To say, however, that the "frigorific mixture" has failed in many cases, is saying nothing more against it than could be said against ether or chloroform; and the reason of its having so failed, may perhaps be found in the letter of Dr. Berry which precedes the lecture of Dr. Mütter. We are there informed, that in the six operations which he had seen Velpeau perform after anæsthesia had been produced by ice and salt, this mixture had been applied by enveloping the part in a cloth containing it. A similar expedient was employed by myself at first, but it does not answer the purpose nearly so well as applying the frigorific by means of a net of very thin gauze or *tulle*; which not only produces congelation more quickly, but enables the surgeon to watch the different steps of the process. It was this last mode of application which I exhibited two years ago to M. Velpeau at the *Hôpital La Charité* in Paris.

In making a comparison between etherization and congelation as anæsthetics, I would solicit attention to the following points:—

1st. The anæsthesia produced is as perfect or complete in one case as in the other, so far as the external and more sensitive parts are concerned. Many operations involve little more than the skin; and in all, it is only the incision of the skin and the tissues immediately adjoining it, that causes very acute or intolerable pain.

2nd. What may be termed *tolerable* pain would, I think, be preferred by many, to loss of consciousness. Whether a surgeon is justified in incurring danger to life, in order to prevent a slight amount of pain, is a question deserving serious consideration.

3rd. There is no danger of a fatal effect or other mischief of a less degree from congelation. Even within the last few months several deaths from etherization have been reported in the medical journals.

4th. The dreaded reaction after congelation, alluded to in Dr. Berry's letter, is not only a delusion, but the fact is, that the opposite effect follows, and that the condition of the vessels produced by complete congelation is a great advantage, inasmuch as operation wounds heal more rapidly after it than under ordinary circumstances. The vessels appear to have lost their tonicity for awhile, or to have become insusceptible of excitement or inflammation.

5th. As there is no unconsciousness produced, the patient can occasionally assist the surgeon in an operation. In opening the urethra in the perineum, for instance, when

a grooved director cannot be passed through the stricture, it is of importance that the patient should be able to distend the urethra, or make the urine flow through the opened canal. In such an operation, also, where there is usually embarrassment from hæmorrhage, the quality possessed by congelation of restraining or preventing this, is another circumstance in its favour.

I shall conclude by stating, in respect to the manner of applying this local anæsthetic, that the tingling which might otherwise follow congelation, may always be prevented by putting a little pounded ice on the part for a few minutes, or a thin bladder containing water and ice. In applying congelation in cancer of the breast, for example (when, however, it is much longer continued than if merely employed for anæsthetic purposes), I find it convenient to suspend a bladder containing iced water over the patient while she reclines on a sofa.

## ON THE NATURE AND TREATMENT OF SOME PAINFUL AFFECTIONS OF BONE.

By LANGSTON PARKER,

Professor of Anatomy in Queen's College, Surgeon to the Queen's Hospital, &c. &c.

(Read before the Medico-Chirurgical Society of Queen's College, Birmingham, October 19, 1852.)

THERE are many affections of bones, whose predominant character is pain, which are hardly to be referred to any of the more well-known diseases of these parts, and which certainly are not ameliorated by the means generally resorted to for their cure or relief. The more common affections of bone, marked by severe pain, are inflammations of the periosteum; of the medullary membrane of the shafts of the long bones; of the bony tissue itself; circumscribed or diffused abscess of bone, and neuralgia. All these varied affections are accompanied by intense pain; in fact, pain appears to be the chief symptom of the disease, and in many instances is so great as to threaten the death of the patient, if not relieved even by so extreme a measure as the amputation of a limb.

The differential diagnosis between some of these affections is, in many cases, obscure, and even the most experienced surgeons have often found it difficult to decide on the exact source or nature of the pain which has had its seat in a diseased bone.

It has appeared to me that many of these painful affections of bone are of inflammatory origin, and that the inflammation is seated in the medullary membrane of the shaft, or that which lines, imperfectly, the cancelli and canals of the extremities of long bones.

The chief anatomical characters of the medullary membrane of the long bones are extreme tenuity, great vascularity, and excessive sensibility. In many characters it differs essentially from the periosteum, which is neither so thin, so sensible, or so vascular. It is through the medium of the medullary membrane, which is supplied in each long bone with its special artery, that the whole of the internal structures of the bone are nourished and supported; and hence it is that death of the bone follows the destruction of the medullary membrane as the experiments of Troja have already proved; and it is equally probable that necrosis of portions of the shafts of the long bones may follow a partial destruction of the medullary membrane from inflammation.

I have just stated that the medullary membrane is very vascular, so much so that it frequently forms a species of hernia from the medullary canal of a long bone in young persons after amputation, this protrusion is the medullary membrane turgid with blood.

It is also common to see the blood issue in a stream from the divided vessels of the medullary canal after an amputation, particularly if the amputation be performed high up, either in the arm, thigh, or leg. There is no question about the source of this blood, it is from the vessels of the medullary membrane. The medullary membrane highly vascular, serves to nourish the internal layers of the bone, it possesses great sensibility and a high degree of vitality. The medulla, or fatty tissue of the medullary canal, is alto-

gether insensible. It has been shown by vivisections, that if a probe be introduced into the centre of the medulla of a long bone in a living animal, no sign of pain is produced as long as the instrument does not touch the walls of the cavity, but whenever the walls are rubbed or scratched, the pain becomes excessive, and is manifested by piercing cries or violent struggles.

A membrane so extended in its ramification, so sensible, so vascular, must necessarily be the common seat of disease; and when we reflect that this membrane is enclosed in an unyielding bony case, it is quite evident that many of its diseases must be accompanied by extreme pain.

In the spring of 1847, Jane Hartshorn, a female of stout, healthy appearance, was admitted into the Queen's Hospital, under my care, suffering from pain in the shaft of the left tibia, which she said had originated from a fall on the knee of that side some months previously, by which the patella was much injured but not fractured. It was considered by the surgeon who attended her in the country, that an abscess had formed over the patella as a consequence of this injury, and an incision was made by him down to the bone, but without the discharge of any matter. From this period she dated the commencement of pain in the leg. At the time of her admission there was severe and constant pain down the whole shaft of the bone, which did not appear to be enlarged, but was tender when it was handled or pressed. A great number of remedies had been tried before she entered the hospital without any relief; and after that time the means resorted to failed in ameliorating the patient's condition; even the complete division of the periosteum, from the knee to the ankle, failed in giving more than a temporary cessation from pain. She remained in the hospital for nearly four months, and left it because at that time I refused to amputate the limb.

A residence in the country and attention to her general health did not in any measure tend to mitigate the pain, which continued to deprive her of appetite and rest; her health began to suffer, she emaciated, perspired at night, and her constitution exhibited symptoms of giving way. A surgeon in the country proposed amputation, and she was actually on the table, preparatory to the amputation being performed, but preferring to lose her limb in the hospital, she came back, and I at length consented to remove the limb, which was amputated in the lower third of the thigh. An unusual quantity of dark-coloured blood flowed in a stream from the medullary canal of the femur when sawn through, and the cavity when this had ceased, was completely filled with dark-coloured coagula. The medullary canal of the tibia was carefully examined throughout; the periosteum was not so firmly adherent to the external surface of the bone as in a bone quite healthy. There was no medulla in the canal, which was quite full of dark, grumous blood, and the membrane universally dark throughout. Mr. Stanley quotes a case from the *Journal Hebdomadaire*, where a very similar pathological condition of the medullary membrane was present. "It was of a deep red colour, resembling the conjunctiva of the eye in chemosis; and in places it was black, with a gangrenous odour." Portal says: "The contents of the medullary cavities may be reduced to a species of putrilage, as a consequence of inflammation; which has been proved by the examinations after death, of bones which have been the seat of severe and continued pains." Hartshorn's stump healed well; and the patient, who had before the operation some threatening of pain in the femur, similar to that which had existed previously in the tibia, continued free from pain till six or seven weeks after the stump had quite healed. Pain then came on in the thigh, and extended to the hip, at first slight, and in the lower part of the bone merely, afterwards becoming more severe, till, as in the first instance, appetite and sleep were lost, the patient began to fall away, and the general health to suffer so much, that it was evident to all some decided course must be adopted to save her life.

It was clear that all ordinary measures would be of no avail in such a case, though many were tried, without success, as might be supposed. The question of a second

amputation was entertained: but here it appeared, that unless performed at the hip, we might have again the same condition returning as after the first operation. It occurred to me, after reflecting on Sir B. Brodie's operation for the discharge of pus confined in the interior of bones, that if a piece were cut out of the femur, and a seton passed through it, that the patient might possibly be relieved, if not cured, without subjecting her to further mutilation, involving the risk of her life. A proceeding of this kind offered some chance of success, from the fact that she had no pain as long as there was discharge from the stump, but when the stump closed, the pain again came on.

Sir B. Brodie records a case which first induced me to think the operation I have mentioned would be of service to my patient, Hartsborn:—"A young gentleman," says Sir Benjamin, "was brought to me from Brixton, with violent pain in one arm, the bone itself being enlarged in the part to which the pain was referred. The pain continued, and an abscess was suspected. Under this impression, an opening was made with the trephine so that the matter might be discharged, if there were any there. The trephine penetrated to the centre of the bone, but no matter escaped. I persevered," continues Sir Benjamin, "but still there was no matter; and at last the instrument penetrated completely from one side of the bone to the other." Sir Benjamin thought he had made a blunder, and there being no matter, the operation would not be attended with any benefit; the wound, however, healed well, and the relief to pain was complete.

It was exceedingly probable, that in Hartsborn's case the state of the femur was like that of the tibia, from what was observed of the condition of the medullary canal at the time of the operation. There was some pain in the thigh before this, but the loss of blood at that time, and the discharge from the stump after, kept down for the time the inflamed or congested state of the medullary membrane.

Having determined to perforate the femur, and pass a seton through it to prevent the cavity being too soon closed by callus, I had a trephine prepared with a long, narrow crown, sufficiently long to pass through the bone. While the patient was under the influence of chloroform, I made an incision, about two inches and a half long, in the inner side of the limb, about four inches above the extremity of the stump, divided the periosteum, and perforated the femur with the trephine; I then passed a long, narrow seton needle, made for the purpose and armed with a thick web of cotton, through the hole in the femur, and brought it out on the outside of the thigh.

There was a great discharge of black blood from the medullary canal of the femur when it was opened by the trephine, which gave relief to pain; and after the discharge produced by the introduction of the seton (which was profuse) was fully established, the pain in the bone, which had so long tormented her, was no longer felt. The seton was suffered to remain through the femur about three months, when it was withdrawn, and the wound suffered to heal. Since that time the patient has remained in good health, and there has been no return of pain in the bone. I have already alluded to the case recorded by Sir B. Brodie, in which he perforated the humerus for pain in the arm, no matter was discharged, but the operation succeeded in curing the pain. It is exceedingly probable that this case also was an affection of the medullary membrane, probably of an inflammatory character, which had been cured by the division of the distended and overcharged vessels in the interior of the bone.

In the year 1848, a young female, named Chatwin, was admitted into the Queen's Hospital, under my care, for a painful affection of the tibia of the right leg. She was of delicate appearance, by occupation a house-maid, and entirely free, as was the last patient, from all venereal taint. Some time before her admission, she had felt shooting pains down the whole shaft of the tibia, which gradually increased in intensity till she could no longer bear the weight of the body upon the leg. The shaft of the bone was exceedingly tender to the touch, but not enlarged, nodulated or uneven;

the pains were rather in the shaft than in the extremities of the bone: in fact, the greatest pain was felt in the centre. Blisters, opiates, iron, the iodide of potass, and mercury, pushed to salivation, were absolutely useless, and did not procure even a temporary alleviation of pain. It was quite evident, that whatever the nature of the disease might be, that it was seated in the interior of the bone. After waiting a reasonable period of time to see the effects of the remedies employed, and finding my patient's health breaking, I determined to pass, as in the last case, a seton through the centre of the tibia, as this appeared the only means of saving the limb and life of the patient. The integument and periosteum were divided in the centre of the inner surface of the shaft of the bone and the bone perforated, so that the trephine came out on the external surface of the bone. The needle, armed as in the last instance, was passed through the bone and soft parts covering the external surface. The pain caused by the operation was considerable for a few days, but the pain for which the operation was undertaken soon diminished, and at the end of ten days had entirely disappeared. If the seton were left unmoved for two or three days, there was a difficulty in moving it, owing to the firm deposition of callus around it; and on its final withdrawal, at the end of six weeks, the perforation was very soon closed by new bone.

It is most probable that operations for the relief of certain diseased conditions of the medullary membrane would be rendered in many instances abortive unless the opening in the bone were kept open, by seton or tent of some kind, and daily watched, as the closing of the opening by new bone is exceedingly rapid. Provisional callus is almost immediately thrown out after the perforation of a long bone by the trephine.

It is quite evident, from the details of these two cases, that the shafts or extremities of the long bones may be opened with success for the purpose of relieving diseased conditions of their interior, besides those which are marked by the formation of matter. It may be asked, what are the symptoms of disease by which such a proceeding is indicated. I should say, fixed and continued pain in a bone, with or without enlargement of its shaft, of sufficient violence to threaten the destruction of the health and life of the patient, and the failure of other remedies adopted for its relief. In many cases, amputation has been resorted to as the only resource in such cases, but I am fully persuaded that the perforation of the bone, and passing a seton through it, will save many a limb which otherwise must have been lost.

Many, if not most, of these cases are doubtless congested or inflammatory condition of the medullary membrane of the interior of the long bones. In some instances such diseases may exist with affections of the periosteum; in others they may be present alone. It is probable that, in venereal diseases, many of the pains in the shafts of the tibia and other bones are due to disease of the medullary membrane, in the absence of all evidence of the periosteum being affected. Astruc and others, it is well known, attributed such pains to affections of the medulla itself; but it is now well established that adipose tissue, wherever met with, is insensible; and the experiments of Bichat and others have shown the seat of sensibility in the interior of the long bones to be in the medullary membrane, and not in the medulla itself. Scrofula, syphilis, rheumatism, and local injury are the most frequent causes of inflammation of the medullary membrane, and are amongst the most frequent causes to which painful affections of the bones can be traced.

I have performed a similar operation, for a painful disease of the tibia, which was of venereal origin, in August of last year, on a girl named Eliza Cooper, but in this case the medullary cavity was opened only. I did not carry the trephine through the bone. The hole made by the trephine was kept open by a tent of lint, changed every morning. The relief to pain was complete; whilst previous to this operation it had resisted all the usual remedies in such states, as blisters, opiates, iodide of potass, &c.,

and had at times been so excessive that she had frequently importuned me to amputate the limb.

I have now performed the operation I have just alluded to, in six different cases for painful affections of the long bones, which have resisted all other modes of treatment, and in each instance with success. No constitutional disturbance of any importance has followed any of the operations. In Chatwin's case the pain consequent upon the perforation of the bone was severe for some days, but this was much more bearable than the pain for which the operation was performed. It subsided at the end of that period, and the patient has since enjoyed the best health. I have seen her two or three times since. She has resumed her occupation as a domestic servant, and suffers nothing from her leg: she walks well on it, and is in good health.

I think, from what I have said, it may be concluded that the shafts of long bones may be perforated or opened for diseased condition of their interior, similar to those I have mentioned, with every probability of safety and success, where all other modes of treatment have failed.

#### TREATMENT OF ANEURISM BY ANASTOMOSIS BY GALVANO-PUNCTURE.

By M. NELATON.

A YOUNG woman, æt. 20, presented herself at the Hôpital St. Louis, on account of a tumour situated in the middle of the forehead, above the nose, inclining a little towards the left side. It was manifestly formed of vessels folded on themselves, and whose tortuosities could be very easily traced by the touch. A very well-marked bruit was also discernible, especially during the arterial diastole.

The swelling appeared, according to the patient's account, after a blow received two or three months previously. The diagnosis was plain—viz., that the tumour was formed by the aneurismal dilatation of the arterial trunks situated in this region.

The situation of the tumour being on the median line of the forehead would have rendered it necessary to ligature both the carotids; so M. Nelaton, rather than perform so hazardous an operation, preferred trying galvanopuncture, which was applied thus: Two needles were implanted in the parts of the tumour where the pulsation was most apparent, and then connected with a battery (Bunsen's) of thirty plates, and acted on by a continuous current for ten minutes. The pain was very trifling even during the action of the battery, and the following day the good results of its application were beginning to manifest themselves. To a small extent round the point where the needle connected with the positive pole had been implanted, a hardness was felt, showing a coagulation of the blood contained in the arterial flexuosities, which formed this part of the tumour.

A second application of the electricity was made eight days afterwards to another part of the tumour, with the same result. Finally, six repetitions were sufficient to check the pulsations in the whole extent of the tumour, and to obliterate the anastomosis of the arteries. The induration after a little time disappeared without the permeability of the arterial varices being reestablished.—*Gaz. Médicale de Paris.*

**DANDELION COFFEE.**—Mr. Jacob Bell, writing to the Board of Inland Revenue, says:—"The recent alteration in the Treasury Minute respecting the mixture of ground coffee with other ingredients, has led to some doubts as to the legality of the sale of a medicinal preparation called "Dandelion Coffee." This consists of the root of dandelion, or taraxacum, prepared and ground with a portion of coffee. It is recommended to patients as a convenient mode of taking dandelion, the value of which is so disguised by the coffee that it is used as a beverage. I should feel obliged if you would inform me whether this preparation is included among the prohibited mixtures of coffee; and if so, how chemists should act when medical men prescribe dandelion coffee for their patients." To this Mr. Ford, Chairman of the Board, replied:—"In such a case as you put, of dandelion coffee used as medicine, our board would not interfere."—*Phar. Jr.*

#### CASE OF COMBUSTION AND DEATH OF THE HUMAN BODY IN THE OPEN AIR—SPONTANEOUS OR NOT?

By JOHN GRIGOR, M.D., Nairn.

ON the evening of the 29th July last, the body of John Anderson, æt. 50, about five feet four inches in height, and of a spare habit, a carter of wood from the forest of Darnaway to the pier of Nairn, and a notorious dram-drinker, was found dead by the road-side, seven miles from Nairn, and in a state of combustion, the process having proceeded so far as blackening and charring of the body and head, and complete disfiguration of the features, so much so that the person was only recognized from his horses and carts being known. The case was taken up medico-legally by the Procurator-Fiscal of the county of Nairn, and I was requested to inspect the body, and report. On approaching the unfortunate man's dwelling on the forenoon of 31st July, I found that the funeral had passed on to the churchyard of the parish of Dyke, and after a little explanation to the attendants, I succeeded in getting a hurried autopsy within the church. On removing the grave-sheet, I found a black incinerated, and stiffened body. The arms and legs were crossed; the latter raised from the chest. The position was one of ease, and the body had not been touched since first rolled up. The eyes, ears, and nose, were burned away; teeth clenched; and from the mouth bubbled out some white froth and gas. The lining membrane on the inside of the lips and cheeks was quite burned; also the edges of the tongue, and the hair and skin of the head. The skin and cellular tissue of the body were much charred, the thighs not to the same extent, and the burning had ceased about midway between the knees and feet, where there was a reddish and slightly blistered line. The back was not so much destroyed. The pharynx, œsophagus, &c., exhibited no appearance of burning. The villous coat throughout was much congested, and that of the stomach presented those cherry-red appearances, with thickening, which are sometimes noticed in the stomachs of drunkards. It was almost empty, gave out no smell of alcohol, nor did the contents on after-examination. On opening the peritoneum, there was a great escape of fetid gas. The bowels were healthy, but dry from heat. The state of the heart, blood, and lungs, could not be examined.

On inquiry, I found the wretched man's history to be the following:—He has been a carter, as above stated, for several years; has drunk, at least, of ardent spirits daily, on an average, a common bottleful, besides porter, beer, &c.; left Nairn, on the day of his death, intoxicated; in passing an intermediate village, was seen coming on "all fours" out of one of those many "publics" which are the opprobria of our smaller towns and villages in the north of Scotland. He was, however, one of those "soaking" individuals, who much sooner lose the locomotive balance than a knowledge of his situation and work; hence, when on his cart, he could talk and manage his horses tolerably well. He had a brother carter with him, a neighbouring toll-keeper, who was sober; and they parted company at the toll-gate of Harmuir, within half a mile of the place where the body was found. Before this, however, Anderson wished his pipe to be lit and handed to him; but his friend, thinking that he had no need of a smoke, merely put a little fire on the old tobacco ash, when he drew, and immediately said, "She is not in." The conversation went on for ten minutes, when the poor man turned his horses' heads homewards. All this time the pipe was in his hand. The toll-man, who was much on the road with him, declared that Anderson seldom lighted his own pipe, and never almost knew him to carry lucifers. The dress was a woollen shirt, canvas frock, corduroy trousers, and "a wide-awake." The weather was very warm and dry. When a little farther on his way homewards, smoke was seen rising up from the cart in which the man was, and which contained a good deal of hay, by a herd-boy on a neighbouring rising ground, about one-fourth of a mile distant. The man was next seen to descend from the cart, to stand,

then to stagger and fall. The horses stood still. In a few minutes, smoke again appeared from the ground, when the boy ran down, and found the body lifeless, black, disfigured, and burning. He hurried to a cottage close by, and returned with a woman having a water-pail, with which they drew water several times from a rivulet almost at their feet, and thereby extinguished the burning body and garments. The position was on the back, inclining to one side; arms and legs as before mentioned. The time that elapsed between the boy seeing the man come down from his cart and the water being dashed on, is represented as not more than fifteen minutes. The body was wrapped into a sheet, and removed home. The pipe was found lying below the body with the cap on, apparently as it had been put into his hands. The clothes were all consumed, except the lower parts of the legs of the trousers, where the burning had ceased, and a small portion of the shirt, frock, and hat, immediately between the body and the ground. There was none of the hay burned.

*Remarks.*—The case at first sight appeared to me to have arisen from the clothes having by some means caught fire, and the smoke therefrom producing death by asphyxia—the subject being much intoxicated; but second thoughts demonstrated a few points not reconcilable to my mind with this view, such as the position on the back, &c., the event taking place in the open air, rigidity of the limbs—no trace of fire—and the rapidity and extent of the combustion, whilst this latter (compared with the accounts of martyrs, suttees, and others who have been consumed, and the great quantity of fuel and the time that have been required) and no apparent struggle or attempt having been made to cast off the burning garments, or to quench the flames in the brook running alongside, whilst the man was not at all in a state of insensibility from his potations, led me to the belief, that it was no ordinary combustion from the application of fire. I have then been induced to regard it as a case of progressive igneous decomposition, commencing during life without the application or approach of any hot or burning body, as believed in by several continental physiologists of eminence. Such a state of matters I know has been regarded by many as almost fabulous; but the numbers of general instances from good authorities, and from all parts of the world, of spontaneous combustion, or, as Beck more properly terms it, preternatural combustibility of the human body, and written on by Dr. Mason Good, and received into the Statistical Nosology from the General Register Office, now in the hands of most medical practitioners under the appellation of *Catacausis Ebriosa*, show that the doctrine cannot be wholly set aside. It is not my intention to lengthen these observations by quoting cases, the popular reports of the nature and causes of many of which I will allow are valueless from misrepresentation, and “biased by alarm, credulity, stupidity, and a love of the marvellous;” yet there are many British, continental, and American authors, whose favourable testimonies are very valuable. Nor will I inquire into the chemical possibilities of the generation in the body of inflammable gases, such as hydrogen, phosphuretted hydrogen, &c., nor into the existence of oil in the serum of the blood of the habitually intemperate. And as regards the alcoholic theory, in the sense of the popular advocate for temperance, I will take leave to quote, from an article in the last July number of the *Edinburgh Medical and Surgical Journal*, which embodies the opinions of MM. Liebig and Bischoff on this part of the subject, &c., as evidenced on the interesting medico-legal investigation, in reference to the murder of the Countess Goerlitz, at Darmstadt, in June, 1847:—“To suppose, therefore, that any amount of alcohol, or alcoholic liquor, could cause either the breath exhaled to take fire on the animal tissues being impregnated with it, is to admit an amount of accumulation of this poison in the system totally incompatible with the continuance of life. M. Bischoff states that he is convinced that, though a dead body were soaked in spirits, it would not, in consequence of that, become combustible. He took parts of a dog, into the arteries of which alcohol had been injected at 92

deg. These parts did not burn, either at the flame or exposed upon coals. They became roasted and charred, but ceased to burn so soon as they were withdrawn from the fire. It must not be denied, nevertheless, that this experiment furnishes no satisfactory conclusion against the hypothesis of spontaneous combustion, such as is supposed to be induced by habits of incessant drinking. It is not impossible that, under the long continuance of these habits, the whole organism may be modified in such a manner as to become, upon the application of certain causes, combustible. But in this case it is at variance with everything known, to imagine that the alcohol in the body is the agent or means of the combustion. It cannot be the alcohol that burns. It must be an animal body converted into a combustible body.”

I must here express great regret that it did not occur to me, till it was too late, to apply a light to the body at the time of examination, which would have been almost decisive of this curious medico-legal point.—*Edin. Monthly Jr.*

[Dr. Grigor's case is interesting in a medico-legal point of view, though all the circumstances seem reconcilable with the ordinary phenomena of combustion. We have fire and combustibles about the person of a man helplessly intoxicated,—and can account for what followed, without resorting to the apocryphal theory of spontaneous combustion.]—*Editor of E. M. J.*

## ELASTIC COLLODION.

By M. E. LAURAS.

HAVING made collodion the subject of a special study, and the object which I sought having been attained, I now communicate the good results I have obtained by the *modus faciendi* which I employ.

The important improvement to be made in this compound, which hitherto has not been of very frequent application in therapeutics, consisting in giving efficacy to it and in preventing the sufferings produced by its application on any portion of the body, and principally on the articulations which are much constricted after having been covered with it, an effect due to its want of suppleness and elasticity, and which the skin requires both for stretching and contracting.

By adopting the following formula, every inconvenience is obviated, collodion becomes easy of employment, and enables the patient to move without suffering pain:—

Sulphuric acid of sp. gr. 1.847 300 grms.; nitrate of potassa (very dry) 200 grms. Mix together in a stone-ware or porcelain pot, and add carded cotton, ten grms.

Leave in contact for twelve minutes; withdraw the cotton, wash it with cold water to remove the acid which it retains, and after two or three rinsings, immerse it in water containing thirty grms. of subcarbonate of potassa in solution in 1000 grms. of water; plunge it again into ordinary water, agitate well, and dry at a temperature of 77 deg. to 86 deg. F.

The cotton, thus prepared, takes the name of Xyloidine, and may afterwards be mixed with the ether and the other substances which form it into elastic collodion.

*Elastic collodion.* Xyloidine 8 grms.; ordinary sulphuric ether 125 grms. Place in a wide-mouthed flask, and add alcohol of sp. gr. .825 8 grms. Agitate, and then make a mixture composed of Venice turpentine 2 grms.; castor oil 2 grms.; white wax 2 grms.; sulphuric ether 6 grms. Heat together the first three substances, add the ether, and combine the two mixtures.—*Repertoire de Pharmacie et de Chimie.*

## IMMENSE DOSES OF OPIATES.

A PATIENT of mine has just recovered from his second attack of delirium tremens, who took, in seventy-two hours, the following drugs before sleep was obtained—viz., 12 grains of muriate of morphia, 490 minims of tincture of opium; 28 grains of gum opium, together with 13 grains of tartar-antimony. Having got this enormous quantity of sedative medicine, he slept soundly for eight hours, and awoke quite well. The delirium seemed immediately to follow a severe diarrhoea, which lasted two days, and for which he took nothing but rice-water. He is a fine, hearty-looking man, thirty-five years and a half old, of active, bustling disposition, and was in a state of mania for fourteen days after his first attack, in consequence of being allowed his accustomed potations of gin and ale as part of the treatment. During this, the second attack, he was kept upon beef-tea,

tea, arrow-root, and only six ounces of port-wine, no other vinous or spirituous liquors being given. As I administered most of the doses myself, seeing him every three or four hours, I can vouch for what I have stated. When I had given equivalent to sixty-six grains, taking one grain of morphia as equal to four of opium, I requested the opinion of my friend, Dr. Hamilton Roe, who agreed with me in the necessity of continuing the treatment. I have no time to look up authorities, but I believe none except the American physicians give opium as largely as was done by me in this case. Of course I do not mean to say that any more should be given than will procure sleep, or that the disease should be treated without ardent spirit, wine or beer, but I should suggest their use being more confined to cases exhausted by long-continued intoxication; just, indeed, where morphia and tartar-emetic for obvious reasons would be inadmissible.—*Mr. Wm. Thorn in Lancet.*

#### REVIEWS AND NOTICES OF BOOKS.

**MORAL-SANITARY ECONOMY.** By H. McCORMAC, M.D., Consulting-Physician to the Belfast General Hospital, Visiting-Physician to the District Asylum for the Insane, Recent Professor of the Theory and Practice of Medicine in the Royal Belfast Institution, Corresponding Member of the American Institute, Washington, &c. 8vo. pp. 150. Belfast. 1853.

We do not propose to give a formal review of this brochure; for its scope is so comprehensive, and its topics so multifarious, that it would well nigh require much print and paper as itself for a complete criticism of the contents. This, however, matters little, inasmuch as a copy of it can be had for a shilling. Without any intention of unnecessarily soliciting attention to it, we can, without exaggeration, say that it is a production well adapted to the wants of this country and the state of society which now prevails. If there be a people on the face of the earth requiring a severe lecture on their tastes, habits, and propensities, as regards physical wants and animal requirements, it is the Irish, and such a lecture Dr. McCormac endeavours to give: not in the language of reproach, or in an arrogant spirit, but in terms of persuasion and with feelings of respectful regret. Whatever people may please to think respecting the work, they must admit on its perusal, that the author is sincere; nay, perhaps they may call him an enthusiast. If he be not a true philanthropist, we are greatly mistaken, and no wolf in sheep's clothing, assuming a character for humanity to gain his private ends. Many of our readers will sneer at the notion that such a being can exist as a sincere, enthusiastic philanthropist, hardened as their hearts have been by the professions of impostors pretending to act in such capacity for personal objects; but history at all events tells that such have from time to time appeared. The following is the table of contents: Female Degradation—Employment—Education—Household Culture—Criminal Management—Physical Training—Clothing—Food—Drink—Air—Drainage—Prevention of Disease; and under these heads we have an abundance of details and a profusion of suggestions; not, it is true, derived from, or applicable to Ireland exclusively; but still well suited to the amelioration of its condition. The deplorable state of the labouring class of the Irish is often attributed to some inherent depravity, some instinctive brutal propensity, or unaccountable defect of character; but it is no such thing. It is the result of a coincidence of physical causes and moral influences in operation for ages. The following extract from Dr. McCormac's book furnishes our readers with proofs of this, while it affords at the same time a specimen of his method of handling his subject:—

“However miserable the Irish poor, there seems, every

opposing invective notwithstanding, a powerful element of self-helpfulness in the Irish character. ‘The most thriving and industrious in all our colonies are the Irish.’—*Edinburgh Review*, January, 1850. ‘Irish labourers, removed to situations in which industry is rewarded, exert themselves strenuously.’—*Thornton's Plea*, p. 236. ‘It is nearly impossible (observes Mr. Godby in his *Letters*) to detect any difference in the United States between those of English, Irish, and Scottish blood.’ ‘The success which has attended Irish emigrants in every country where they could obtain a fair day's wages for a fair day's work, affords the most conclusive answer to their habitual vituperators.’—*Sun*, October 16, 1851. ‘Irishmen (affirms Mr. Carlyle) are the sorest evil England has to strive with,’ while the *Times*, September 3, 1850, at one time the mouthpiece of every prejudice, at another the exponent of the better interests of humanity, declares more justly that ‘they are the indispensable auxiliaries of British industry.’ Many, indeed, are their dreary pilgrimages: now in the loathsome passage across the Irish Sea, now over the Atlantic wave, all in pursuit of leave to toil. One million sterling, it seems, was sent by Irish emigrants from the United States to Ireland in the single year of 1851. ‘Seeing these poor fellows toiling amid water and mud, and in the face of the hardest rock, I was convinced of the untruth of the charges brought against them.’—*Saxon in Ireland*, p. 82. ‘Englishmen talk of the indolent Irish! The accusation is false. They dig our canals, grade our railways, sit in our courts and legislatures, and are willing to work at any service as any people on earth, and with a fortitude that surprises us.’—*Balch, Ireland as I saw it*, New York, 1850, p. 169. ‘No one but a New Englander could have conceived the possibility of surmounting those rocks, chasms, and wintery heights, levelling them practically with the banks of the Connecticut. There those adamantine butments will stand, and at the end of time will bear the marks of the Irishman's drill, his bar, and pickaxe.’—*Elihu Burritt, Sparks from the Anvil*, p. 59. Agrarian outrages excepted, crimes against the person, and deep moral delinquencies, are certainly rarer in Ireland than in England. The more recent columns of the English press record outrages on the very name and essence of humanity. In Ireland there are no Brownriggs, Bubbs, Birds, Sloanes, Cheshams, Maria Clarks, or Mary Mays; no examples of opulent persons declining to support their aged relatives.—*Sanitary Reports*, p. 54. Mr. Mayhew, in his late work, bears testimony to the religious principle and moral fervour of what he terms ‘the street-Irish,’ while the costermonger ‘neither has nor knows any religion whatever.’ ‘Too long (observes Mr. Baird, in his *Sanitary Report on Glasgow*) has the bad name of the poor Irish been ascribed to them, but a short inspection will correct the error.’ Dr. Cowan of the same city avers that the Irish exhibited ‘less squalid wretchedness and drunkenness than the Scotch;’ while the Factory Inspector for Scotland, Mr. Stuart, in his *Report to the Secretary of State*, London, 1842, p. 132, adverts to the ‘regular habits, superior industry, and docility of the Irish,’ and the consequent preference accorded them by employers. ‘I have had a good deal to do (observes the Rev. Mr. Osborne in one of his pregnant letters to the *Times*) with English emigrants and their thriving position, yet I have never heard of them sending money to their relatives, whereas instances of Irish good-feeling in this respect might be multiplied to an extent I could hardly bring your readers to believe.’”

#### LETTERS FROM PROFESSOR EVE.

(To Professor Watson of the Nashville University, U.S.)

London, July 31, 1852.

WITHIN the few days, since my last letter was written, I have seen the Hunterian Museum, Guy's, St. Thomas's, and St. Bartholomew's Hospitals. Were I sentimental, I might add I have seen Professor Owen, the great naturalist, the veteran surgeon Dr. Lawrence, and Dr. Babington, and stood by the grave of Sir Astley Cooper.

Of the three great men of the age, and I name them in their proper order—Humboldt, Arago, and Owen, I have the high honour of making the acquaintance of the latter. I found him in his study in the Hunterian Museum, hard at work, but which he immediately left and accompanied me into the immense collection of comparative anatomy, physiological and pathological specimens, of which he is now the curator. The gymnoticus, or electric eel, is here beautifully delineated by Mr. Owen. We see first the natural fish, then its voltaic-like battery greatly magnified, and the wires (nerves) for conveying the electricity. He mentioned to us

a peculiarity in the common gar fish, which is, that of all its species it alone could shake its head. At the junction of the head and neck in the vertebræ, there is an orbicular articulation or balance socket-joint by which this movement could be made; so that, Mr. Owen humourously remarked, this the gar usually did (shake his head) when taken out of the water, to signify that he did not like it.

The celebrated case of "injured chest," which I had seen before, was pointed out, as also another of more recent occurrence. The first is that of having the body transfixed by a pig-shaft, the patient living eleven years after the accident. A gentleman, unaccustomed to horses, drove one up to the door of a stable, and wishing to unharness him, took off first the bridle. The animal, seeing the vehicle behind him, became alarmed, and plunging into the open door transfixed the master with the shaft. Seeing his imminent danger, two persons came to his relief, and drew him off the end of the shaft. He applied both hands to his chest and said, "I don't think the vitals are touched," and immediately fainted.

The exact nature and extent of the injury were not ascertained until after the death of the patient. The foreign body passed from the left through to the right, taking the intercostal spaces of the second and third ribs of both sides. It fractured the second and third ribs of the left, and the second of the right side, and also the sternum transversely. The tug of the shaft passed not only into the thorax, but penetrated the left lung, a portion of which is still seen adherent to the internal costal surface. Both lungs were transfixed. The life of the patient, as Mr. Owen stated, was undoubtedly owing to the bluntness of the instrument causing the wound, making it valvular, and preventing fatal hæmorrhage. The anterior portion of the thorax of this patient, as a wet preparation, and the shaft of the gig, are both preserved in this museum, and are exhibited as a most extraordinary instance of recovery from extensive injury.

The second case of wound in the thorax occurred to a sailor in 1843. The end of an iron rod attached to a yard for hoisting sail in a vessel, in its fall struck this patient, fractured his lower jaw, the clavicle of the left side, entered and then transfixed the thorax. The pericardium of the heart was wounded (Mr. Owen observing he could see the heart pulsate), and the rod coming out just below the left scapula, stuck into the deck of the ship. The chest of this man, there is reason to believe, was thus compressed down to about four inches. He is still in good health, and follows his avocation at sea. The left lung was no doubt transfixed in this case.

The bust of John Hunter recalled instantly the classic face of my great master and his greatest of pupils—Philip Sing Physick. Mr. Owen said this resemblance is noticed by most Americans.

Professor Owen is aged about 55, and has a peculiar whimsical expression; a countenance never to be forgotten. With a wide, expansive forehead, indicative of deep thought and profound study. But the wonderful modesty, the child-like simplicity, even amidst his gigantic works, mark the philosopher. In him I have seen the greatest mind of Great Britain, and, next to Humboldt and Arago, of the world. He has promised me a visit before I leave London, and says a barrel of gar fish put up in spirits would be a very acceptable present from America. This I take to be nearly as cheap as Diogenes' request for his friend to stand out of his sunshine, when he asked what he could do for him.

The hospitals of London are chiefly founded upon charitable subscriptions. They are managed most creditably to all parties concerned. I consider the new one, called the St. Mary, the model hospital, and the chief surgeon, Mr. Wm. Coulson, one of the most gentlemanly persons ever met with in our profession. In St. Bartholomew's, Dr. James Paget is the present curator of its excellent museum, for each hospital is a medical school within itself. He is considered one of the best anatomists in this city, and a most promising young surgeon. I met here, too, old Mr. Lawrence, the veteran surgeon of London, whose acquaintance I made twenty-two years ago; he does not operate, but still may be consulted, and visits the hospital. In the museum, which is quite extensive, are busts to Percival, Pott, England's first great surgeon the eccentric John Abernethy, Henry Earle, and good old William Harvey. I saw Dr. Paget operate for hare-lip, using long steel needles; and then Mr. Stanley cut for stone in a boy four years old. The calculus was very small. The bistoury alone was employed in performing the lateral operation. Mr. Skey was also present. The only peculiarity I noticed was emptying the rectum by a tube before operating. All these surgeons were exceedingly kind,

and Mr. Stanley especially complimentary to our country. I was regularly added to their consultations in two or three cases. One was the decision in reference to amputation in the case of an omnibus driver (a hard drinker) who three weeks ago had sustained a compound comminuted fracture of the lower portion of the humerus. Delirium tremens had now supervened, and his condition was imminently perilous. Mr. Lawrence was for the amputation of the arm a week ago; Mr. Paget decidedly opposed, and Mr. Stanley inclined to it. Upon the whole it was thought best to defer it. I find in this hospital Liston's method of amputation generally followed—viz., the double flap. Mr. Paget was engaged with the microscope, and asked if we did not believe in the difference of epithelial from parenchymatous carcinoma. He was answered in the affirmative. I cannot, however, but believe that the microscope is still uncertain and indefinite. I might have told you that Velpeau had assailed the truthfulness of its observations, and Nelaton asserted that two microscopists of Paris had returned to him different opinions, one declaring that the pathological specimen was cancerous, and the other that it was not of the same diseased lip.

Guy's Hospital was founded by the munificence of one man—a Mr. Guy, merchant of London, and at one time a member of parliament. This was the field of Sir Astley Cooper's labours, where for years he worked most assiduously; and the museum, which is next to the Hunterian collection, presents numerous splendid specimens prepared by his own hands. His remains are here deposited with those of Mr. Guy, in the chapel of the hospital. A monument has been erected to his memory in St. Paul's Cathedral by his pupils and friends. In this museum I was particularly struck with a wax model of the dissection of the head, neck, and arm, by Mr. Hilton. It was on exhibition in the Crystal Palace last year. It is here that wax preparations of a most beautiful and truthful description greatly abound. Mr. Bransby Cooper, nephew of Sir Astley, is the chief surgeon to Guy's Hospital, and Drs. Babington and Barlow its physicians. It and King's College Hospital are undergoing extensive improvements. That our Nashville friends may understand how the funds are raised for these alterations, I may mention the fact that one gentleman gave 2500 dollars and seven others have followed his example.

I accepted an invitation to inspect Barclay, Perkins, and Co.'s brewery of porter, ale, &c. It was established ninety years ago; the capital invested is 35,000,000 dollars; it covers thirteen acres near London Bridge; employs four hundred men and one hundred and sixty horses, and an engine of forty horse power. Two thousand barrels of fermented drink are turned out per day. The Thames water is preferred; an artesian well of three hundred feet deep gives an abundant supply, but it is too hard for use. But the medical point is, the great quantity of carbonic acid gas generated in the manufactory of these compound—and, I may add, confounded—drinks. As soon as I entered the premises, my eyes began to smart, and I came home to suffer the whole afternoon and evening from them. The phenomenon which attracted the attention of Dr. Black fifty years ago is here manifested on a large scale. The gas, after filling the immense vats, pours over the edges upon the floors, and descending into the lower parts of the building, has extinguished life in several instances. This mysterious agent is of course invisible, and insensible too, as you stand up higher than the vats; but bring your nose to the edge, and you are made to rebound by the pungency of the odour. Dip your hat into the vat, bring it out on a level, and it apparently contains nothing but atmospheric air; but turn it then over your face, and you are instantly made sensible that it contained another æriform fluid, which will also extinguish all flames. How soon the mystery of these phenomena would cease were this gas only coloured.

A visit to the British Museum convinced me that it was worthy of this great nation. It is peculiarly rich in its Egyptian collection, mineralogy, and zoology.

One subject has pained me, to see so many Frenchmen, some of our own profession, living in comparative destitution in this city, exiled from their own country by one of the most despotic governments that ever cursed France. Dr. Deville I met several times; he is certainly one of the most learned of his age in medical science, was chained to a common criminal, lived on beans, and banished to Cayenne, when the faculty of Paris interceded for him. I have now but to visit Edinburgh and Dublin before bidding adieu to old Europe, and in this transatlantic letter a few reflections may not be amiss.

The comparative estimate of life in the old and new world.

strikes every American. It is said that not an accident occurred at the exhibition in the Crystal Palace last year in London. How perfect must have been the arrangements which permitted the commingling of nearly 100,000 strangers a day in a very limited space for months together without one serious result to human life. Every precaution seems to be exercised. It is not simply "look out for the engine when the whistle blows," but you shall not go in the way of it, for bars are put up on the railroads as the trains pass; and then every death, every accident, is most thoroughly investigated. The coroner, as he always should be, is an educated medical man, and the guilty are promptly punished. While property is well secured by the laws of the United States, life itself, it must be acknowledged, is there too often sacrificed most recklessly.

The intercourse between the old and new world is still very limited. In the report for the month of June in Paris, this year, of 6050 strangers there were 512 from the new world. The literary intercourse, barring the thieving, is not yet much. A genuine Yankee said to me the other day that there was little difference between the parties, both denying the copyright to authors. The old produces most, but the little original written in the new world is republished without any acknowledgment of its source.

The increase of liberal sentiments in Europe, particularly in England, is gratifying to every American. During this, my fourth visit to the old world, this subject has been quite apparent. I have heard one of the editors of the *Lancet* maintain the opinion that it was of no importance where the candidate for the honours of the profession obtained his medical knowledge, so he possessed it. No special hospital, no favourite professor, no fashionable school conferred it, said he, but every man must be tried by his own merits. This, you will admit, is good republican doctrine. On every side we behold these sentiments becoming more prevalent. Checked they may be at present in France, but the world is improving, growing wiser, and man's inhumanity to man gradually ceasing, to be known, we hope, soon no more.

Edinburgh, August 7, 1852.

Occupying, as you do, a corresponding position in the profession to the teacher of obstetrics in the capital of Scotland, I have thought it appropriate to address you on what I saw to-day. I have had the enviable privilege of not only making the acquaintance of Professor Simpson, the introducer of chloroform, but have seen him operate after administering it. Having visited the Edinburgh University, Herriot's, Dawson's, and Donaldson's magnificent hospitals, each founded by the munificence of individuals bearing these respective names, I made a call on Professor Simpson. He invited me into his private operating-room, to reach which we had to pass through two stories of women, in attendance upon him.

Professor Simpson had just operated upon a case, that of cupping directly the uterus for amenorrhœa. The fluid extracted was subjected to the microscope, and exhibited blood corpuscles, as well as those of mucous and epithelial cells. This method to bring on menstruation is resorted to when other means have failed, and is only adapted to a certain class of cases. A stem-pessary he also frequently employs, composed, for this particular purpose, of two metals—say zinc and copper, or silver—so as to excite galvanic action. These instruments are generally made of German silver, are of oval shape, of about one and a half by two and a half inches in size, and from their centre projects at a right angle a stem of two inches in length. To introduce this pessary, the stem is placed flat upon the body of the instrument, passed into the womb, and then by a spring maintains its position in this organ, while the whole is retained in the upper portion of the vagina. I saw one removed that had been worn ten months without any inconvenience, but on the contrary with advantage. No difficulty is experienced in wearing them. Should the ordinary treatment for amenorrhœa fail, and galvanism produce no effect when applied as described, then, as the *dernier resort*, a long catheter is introduced into the womb, and a suction-pump adapted to its external extremity. This is the direct cupping of the uterus, and is surely one certain emmenagogue. Of course, if the ovaries are at fault, nothing can reëstablish menstruation; hence I have stated this heroic measure, the immediate action upon the womb itself, must be applicable to only a limited number of cases. The sudden congestion of this organ by this means, must often result in the irruption of the menses, and may be added to our means to effect this end.

For retroversion and retroflexion of the uterus, Dr. Simpson relies on his stem-pessary. In a case just arrived

from Aberdeen, the patient was placed deeply under the influence of chloroform, the misplacement clearly ascertained, and as the os tincæ would not admit the stem, it was freely excised in opposite directions. The patient was to return in a few days to have a pessary adapted to her case. I was much surprised at these bold operations upon the womb, and they go far to establish the position of Jobert of Paris, that its internal surface is insensible. The instrument of Professor Simpson for stricture of the os tincæ resembles the lithotome caché, the handle being much longer.

False conception is readily detected by the relaxation produced in the abdominal muscles from the effects of chloroform. Professor Simpson's mode of administering chloroform is as follows:—He poured on a towel about half an ounce of this fluid, and applied it closely to the nose and mouth of the patient. It was there retained about two or four minutes, until the patient had passed into stertorous breathing. Indeed, it seemed to be recklessly administered, so obviously was confidence placed in its harmlessness.

Everything that I saw of Professor Simpson during this brief visit impressed me with the sound philosophy and great merit of the man. He is, in my estimation, justly entitled to all the honours bestowed upon him by his professional brethren throughout the world, and has conferred an inestimable boon on suffering humanity. To him, and to him alone, belongs all the praise of introducing the best anæsthetic yet known in the practice of the healing art.

Professor Simpson is aged about 50; is a short, stout-built man, with broad shoulders, short neck, and large head, covered with a profusion of dark-coloured hair, which he wears quite long. It was four p.m. when I called upon him, and found his house then thronged with female patients, not less than sixty, I should think.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, DECEMBER 29, 1852.

### THE MEDICAL CHARITIES OF IRELAND.

In our last we acknowledged the receipt of a pamphlet on this subject by Mr. ELLIS, lately President of the College of Surgeons, and signified our intention to notice its contents in our present number. It is the substance of an Introductory Lecture delivered to his pupils at the commencement of this Session, with extracts from replies to his letters seeking information, and an Appendix containing the forms to be filled up by the Dispensary Surgeons. Of Mr. ELLIS's motives and objects in thus embarking on the troubled waters of the ocean of medical grievances, we can speak in terms of approbation only. Be his views right or wrong, adverse or favourable to our own, we must give him credit for honesty of intention and disinterested zeal on behalf of his brethren; for we are firmly convinced that he entertains no latent longings after place, or designs upon consultation patronage. This it is necessary to say after all that has passed on this subject. Mr. ELLIS sets out with an avowal of his hostility to the Dispensary Act, and the regulations made under its authority: and we do not quarrel with him for it. Such grievous injustice has been inflicted by its enactment, and such hardship by its operation, that no one can object to an attempt to provide a remedy for them. Our readers will, we hope, recollect that from the very commencement of the agitation for promoting this measure, we warned the parties concerned that such results were to be expected from it; and it was not until, with their consent, it was adopted, that we consented reluctantly to accept it. Be this, however, as it may, there it now is, and we can only hope to amend it, for its repeal is out of the question. Mr. ELLIS sums up his objections to the act and its practical operation as follows:—

1st. The arbitrary and unconstitutional powers given by

the act to the Commissioners to "define the qualifications of the medical officer," and to dismiss him on what they (an irresponsible body) might, in the infinity of their wisdom, consider "sufficient grounds," appear to me to be so much at variance with the liberal policy inculcated and acted upon at the present time, that I think the authors of the bill must not have contemplated the usurpation and despotism involved in their own legislation; and yet, judging from the *enslaving* rules and regulations prescribed by the Commissioners for the medical officers, there is reason to believe that they are not at all unwilling to maintain in full force the plenitude of their authority!

2ndly. In consequence of the length of time which elapsed after the passing of the act, but before the dispensary districts were defined, and the managing committees appointed, the medical officers lost several months' salary.

3rdly. The dispensary districts are entirely too large, whilst the salaries of the medical officers are unjustly and offensively small.

4thly. The frequent returns required by the Commissioners as regards patients, medicines, and medical appliances, are truly ridiculous.

5thly. The complicated system of bookkeeping is most vexatious, and the requiring of the medical officer to attend in cases of midwifery, to vaccinate every person who may be brought to him for that purpose, to certify for dangerous lunatics, attend the inmates of bridewells and houses of correction, and keep an account of the medicines used in these institutions, without any remuneration whatever for such extra-duties, is an intolerable piece of injustice which ought not to be borne with any longer!

Touching these items *seriatim*, we cannot avoid allusion to the first, relative to the power given the Commissioners to define the qualifications of the medical officers, but we must deal tenderly with it, as this is not a very appropriate occasion to discuss the matter. The conferring of such powers on such parties is radically wrong, but who is to blame for it? The Crown and Parliament conferred them on the medical corporations, and they failed to execute them, until absolute necessity compelled the legislature to provide a check elsewhere. From the farrago of Degrees, Licences, Diplomas, and Certificates put into circulation, a selection must be made, and it is better that it should be made by the Commissioners than by the Dispensary Committees. However it may be hereafter, it must be acknowledged that the Physicians and Surgeons of Ireland are indebted to this non-medical body for refusing to accept an Apothecary's Licence to open shop as equivalent to a Medical Degree or Surgical Letters Testimonial. The second grievance, being that of the repudiation of a debt due to the Dispensary Surgeons, is a positive and tangible one. Either the Grand Juries, the Guardians, or the Chancellor of the Exchequer, owe a balance of salary to the Surgeons who discharged duties between the period when the old dispensaries became defunct and the new ones came into operation. But then how is it to be recovered, or from whom? If the claims under this head be so numerous, and the amounts so considerable as to "make a case" for parliamentary interference, it should be pressed; if not, they must go into the balance-sheet as bad debts. Of the grievance of large districts and small salaries, there can be no question; and where it prevails, no rest should be given to Committees, Guardians, or Commissioners until an evasion so obvious of the spirit and intention of the act be prevented. We call it an evasion, and it is nothing else, for the relief of the sick poor by any such means is physically impossible, and the Guardians know it; but what care they for the relief of the poor when the ratepayer is to be relieved? Of the filling up of complicated forms, we have often expressed an opinion; but then is it argued that no account of patients, cases, and results should be taken at all? As far as the relief of the sick poor goes,

we lag so far behind in the march of intellect that we think it matters little to them whether they are "booked" or not; and it only remains to be determined whether "the Doctor" is to draw up statistics for the promotion of science and the advancement of sanitary speculations for the pure love of the thing. Of the fifth paragraph of grievances, there can be no defence set up. To compel a man to administer medical relief to the sick poor of a district of excessive dimensions for £60 a year, and to compel him to vaccinate, attend midwifery cases, certify for lunatics, and attend prisons "into the bargain," is, as Mr. ELLIS says, an intolerable piece of injustice; but it is law, and where is the remedy? We see none, except in an alteration of the law, and how is that to be effected? We have 105 Members of Parliament from Ireland, but they are so busy at their trade of cabinet-making, they can spare no time for such matters as this. We have about a thousand men holding medical offices in Ireland; can they not find a peristaltic persuader to move the bowels of compassion of these gentlemen, or a blister, sinapism, or actual cautery to rouse their sensibilities? A crisis affords an excellent opportunity for the exercise of a practitioner's skill and the development of his resources, and it should not be neglected.

Since the above was written, the following came to hand, and being to the point we append it here by way of postscript. The suggestion contained in it is a good one, and until it and more be adopted, we shall have no end to the fraudulent extortions of small farmers and still smaller landlords:—

A few facts respecting the management of the dispensaries of Ireland, under the old and new acts, and a useful suggestion for the better working of the latter, may not be out of place at the present period. Under the former system, the amount collected by private subscriptions got a like sum from the county, out of which the doctor's salary and the cost of medicine, with all *etceteras*, were paid; then each subscriber commanded the attendance of the medical man, not only for the poor who applied to him, but also for his servants, and very generally for himself and family, with a very few honourable exceptions. Now, having gotten under the Poor-law Commissioners, the committees find that their grinding, selfish tyranny is in part at an end, they not only have the poor of their districts attended to, but they compel the medical man to attend the farmers, and other persons, who are better able to fee a medical man than he is to do without it. Whether this is with the intention of doing good at our cost, or with the view of being able to extract more rent, I leave it to the Commissioners to judge. This I know, that there is no cajolery, device, or plan to take the physician's labour and skill without payment, or at the least possible cost, that is not put in requisition; and after a life of danger, great labour, anxiety, and trouble, if he survives, worn out, heartbroken, and penniless, without pension or reward, except the luxury of having done good, and the State some little service, with the feelings, education, and habits of a gentleman, he may fly where he can to hide himself, and can truly say—"I cannot dig; to beg I am ashamed;" and like that noble animal the horse, when he has done his work, he is cast off, without even the privilege of being sent to the nacker's. My suggestion is, that each dispensary should have painted in large red letters, on a broad place over the door, "Pauper Dispensary," and the days of attendance in white or black; also "Pauper Ticket," in large black letters at the top of the "Visiting Ticket," and in large red on the "Black Ticket." I need not inform you, who know this country well, that this will wound the mean Irish pride of those who would rob us of our just reward, and might make them act more honestly; however, it will be an adjutant, and let some one else propose something better. Finally, let all medical men unite, and put in action their knowledge and great influence to gain an honourable and independent position in society, and to resist their tyrants to the death; and it stands them upon, as their very existence, and that of all they hold dear, depends upon their doing so.

## THE MEDICAL PERIODICALS.

THE following is the manifesto of the conductors of what may be called a new journal. The Provincial Medical Association of England having been for some years endeavouring to support a provincial journal for the use of its members, but without success, now resolves to try its fortune with a metropolitan one. We wish them success with all our hearts, for truly the present state of London medical literature requires a little of the stimulus of competition.

The influence of the "fourth estate" on the march of civilization—its good and evil effects upon the moral as well as the physical condition of man, are uppermost in the minds of most of our leading politicians, and will form an interesting object of inquiry for future historians. During the first half of the nineteenth century, the medical press may be said to have struggled out of chaos into existence; and another Sprengel, in writing its history, will have to take into account the influence of periodical medical literature on the progress of medicine both as an art and as a science, which has not yet been duly appreciated. The vigilant control which it has exercised over the practitioners of the art, has been of great service to society, for though they have the power of protecting themselves—even if they do not exercise it—against neglect or malpractice, yet when the poor are concerned, what other protection can they find but in the loud-toned voice of the medical press? With regard to the science of medicine, we believe that the vast improvements which have taken place throughout Europe and America during this period are mainly due to the same fostering hand. It has kindled in the minds of thousands a spirit of observation previously dormant, making every journal a valuable mine of facts and opinions, at the service of the master-minds who have the time, the energy, and the genius to mould them into profitable shape. Nay, more; the medical press has been the parent of most of the standard works of the day, many of which their authors would have been afraid to publish had it not been for the fostering dew of editorial praise. If such be the nature of a power which, to the best of our abilities, we have wielded for the advantage of the profession, it may be worth while to glance at the present state of so potent an influence, to which, when these words see the light, we shall have ceased to belong. In England, the medical press is now in a state of transition; most of its established organs are changing either their constitution, their form, or their editors; whilst fresh journals are springing up in the place of others consigned to oblivion. Out of courtesy, however, we will first glance at the sister kingdoms. In Dublin there is a quarterly journal, second to none in every valuable quality, and a bi-monthly one, which is edited with spirit, although the tenor of its recent remarks on English practitioners cannot be admired. In Edinburgh there are also two journals—a quarterly and a monthly. The former has become a bookseller's speculation, and now lives on its old reputation, and unless renovated by young blood must speedily die a natural death. The latter is the property of Messrs. Christison, Syme, Simpson, and Bennett, and is certainly conducted with great energy and talent; but its most striking peculiarity is the loudness with which it echoes every month the praises of one or other of its proprietors, whilst at the same time its editors lose no opportunity of bespattering with mud all other British medical journals, especially the hebdomadaries of London. In England, the most important arbiter in medical literature—the *British and Foreign Quarterly Review*—takes a new editor, who intends to introduce original articles; an alteration to be regretted, as it will draught from other journals their most important contributions, without improving its peculiar characteristic of reviewing in a style and to an extent which no other journal can aspire to. The *London Journal of Medicine*, a monthly periodical, dies for want of support, after a short career of profitless respectability. The *Medical Times* at one mouthful has swallowed up the *Gazette*, but, like Pharoah's lean kine, it does not seem to have grown the fatter. It, having used-up one editor, is now in the hands of a highly respectable gentleman, but he has received notice to quit, and another judge in *re medicâ* is said to be coming from beyond the seas. A formidable rival to the old standards has sprung up of late in the shape of the *Medical Circular*, which is a useful compilation from other journals, and has certainly its cheapness and pungency to recommend it. But towering above all still appears the *Lancet*—the

*Times* of the profession—as verdant and sapful as when first started by its energetic editor. Nevertheless, the spirit of change has come over our own Association, or at least an active division of its light infantry; and this journal is henceforth to be so altered as to enter the lists in competition with it. Two weekly journals are absolutely necessary to ensure freedom of discussion; and without that number we should, in London, share the fate of the profession in Edinburgh, where notoriously there is no free press. The *Medical Times*, backed by the staff of two old-established journals, and by the influence of the chief medical publisher of the day, cannot do much more than pay its expenses, and is mainly kept in existence for other purposes than as a merely mercantile speculation. Will the new series of this journal be able to take the place of the *Medical Times*, and compete with the *Lancet*, on the same terms and with the same weapons? Time will show. Will our members be henceforth more willing than they have been to enhance the value of their own journal by the results of their daily experience? We shall rejoice if such be the case, for we have henceforth a common interest with them in the success of our common property. And now one word for ourselves. We have brought the *Provincial Medical and Surgical Journal* to the termination of the first stage of its existence, and as it has hitherto been almost exclusively the organ of the members of the Association, it cannot be out of place to record our thanks for their support. We cannot view a change which renders necessary our severance from the *Journal* without regret. To feel otherwise, would be to appreciate too lightly the honour done to us by the Association in confiding its important interests to our care; and we own our regret is increased by the fact of our having indulged the hope of carrying out, by the aid of our friends, the most signal improvements in its composition and management. Henceforth, as an humble member of the Association, we fervently hope the change may realize the fondest wishes of those by whom it has been brought about, and that it may prove equally profitable to the Association and creditable to the gentleman who will in future occupy the chair we now vacate.—*Prov. Jour.*

With the opinions of our new contemporary touching medical journalism in general, past and present, we have not just now either time or space to deal; but we must find a little of both for a word on a "bi-monthly one in Dublin, which is edited with spirit, although the tenor of its recent remarks on English Practitioners cannot be admired:" meaning doubtless our peccant selves, notwithstanding the misdescription touching our periods of publication and numerical value. As our new Editor gathers experience in his calling, he will discover that THE DUBLIN MEDICAL PRESS will visit him on every Wednesday in the year; and we hope that amongst other improvements, he will introduce that of not ignoring our existence lest we might perchance detach a subscriber. As to our remarks on English Practitioners, we wonder not that they should be repudiated by the organ which speaks for them; but then the remarks may nevertheless be to the purpose. Pampered as these gentlemen have been with nauseous praise and fulsome flattery, a little plain truth may not prove amiss. We cannot, however, complain, seeing the castigation inflicted on our obstreperous brother beyond the Tweed and his ancient relative; nor yet, again, do we repine when we contemplate the semi-ironical sketch of London journalism as it is. Everything, however, to the contrary notwithstanding, we sincerely rejoice that there is a prospect of improvement in our department. We have had too much of "the trade" of late in our speculations, and the prospect of something less humiliating is refreshing.

## MORE ABOUT "THE GREAT CHEMIST."

Or all "the great chemists" that "some folks have read on," not one seems to have been so much indebted to the periodical press for a reputation as the "illustrious Professor of Giessen." BLACK, LAVOISIER, PRIESTLY, DAVY,

and FARADAY, have had a word of eulogium from time to time, but LIEBIG has had more than enough. How is this? Just because certain gentlemen would fain be considered little LIEBIGS, and can find no better method of winning the distinction, than interlarding their lucubrations with their hero's name. But let the be-puffed Professor beware, or he may some fine day find his reputation vanishing in some such vehicle as the froth of Bass's pale ale. Here, however, is the last:—

**LIEBIG MEDAL.**—A medal of considerable artistic merit has just been issued by the celebrated medalist, Ferdinand Korn, in Mayence. It has been struck in honour of the great chemist, Justus Liebig, whose numerous friends will be happy to learn that the artist has secured the right of disposing by sale of a number of copies. The medal is of a diameter of twenty Rhenish lines. The obverse presents a striking likeness of the great chemist. The reverse presents an allegorical composition, consisting of a number of figures, among which the four principal ones are the personifications of science in general, chemistry, botany, and mineralogy; the others, representing other sciences bearing upon chemistry. The whole is a noble and spirited work of art, and an adequate tribute to the great merits of M. Liebig.—*Lancet*.

### THE MUTUAL BENEFIT SYSTEM.

51, Mortimer-street, Cavendish-square, Dec., 1852.

SIR,—Having by a chemical investigation of tubercle, obtained (as I believe) a clue to distinguish true consumption from the many cases of pseudo-consumption often mistaken for it, together with a successful plan of treatment, I am desirous of extending my sphere of observation beyond the limits of my private practice. Should, therefore, any cases of chest disease fall in your way, I shall be happy to attend them *gratuitously*, and also any cases of liver disorder, obstinate dyspepsia, gout, dropsy, urinary disease, and generally all cases caused by, or associated with, chemical disturbances of the system or the secretions. If, in answer to my request, you send any persons to me for gratuitous advice, please to write the name of the patient on your own card, or on a slip of paper with your name and address, which will always enable me to send them my best attention.—Your obedient servant,

JOHN GARDNER, M.D.,

Editor of Liebig's Letters and Lectures.

To Mr. J. Brown.

P.S.—I shall not fail to recommend all patients you may send to me to take my prescriptions to you, that you may supply them with the medicines they may require.

Now, we execrate this Liebigian Editor for his barefaced avowal of such practices as this, but we execrate him because he lets out the secret, not because he does the trick. If he would do all this and more, with all due solemnity, and according to rule, no man would say wrong he did.

### THE TITLE OF APOTHECARY.

How often have we predicted that the attempt to change the name and character of Apothecary for that of Surgeon, Doctor, or General Practitioner, would end in failure. As the following tells, the title has become of such doubtful import that those who bear it know not what to do with it; yet the title, as titles go, is not so bad a one. The vender of culinary chemicals and toilet requisites calls himself Surgeon or Doctor, but we do not find many non-descripts assuming the title of Apothecary: it is too quiet a one for them:—

The title of "apothecary" is so liable to be confounded with that of druggist by the public, that I think those who have obtained a licence from Apothecaries' Hall have a claim to a better designation than that of "apothecary." The examination conducted at Blackfriars should entitle the candidate to at least a respectable title, and one which implies the possession of more than a mere knowledge of pharmacy. It is as searching and as extended as that of many an M.D. Why, then, should the term "apothecary" be preserved? Let the holders of the Apothecaries' diploma petition for a change of title, especially now that there is a Pharmaceutical Society. Why not have the title of "Licentiate in Medicine and Obstetrics" substituted? I am confident that

you will see the propriety of this change of name, as it is intimately connected with the dignity of a large mass of the profession, and therefore likely to aid in making the profession respectable in the eyes of the public.—*Letter in Lancet*.

### MR. KIRBY'S CASE OF FETID ABSCESS OF THE LUNG.

TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—In the "Commentary" on this case, which appeared in the MEDICAL PRESS of the 15th instant, with the object of tracing the disease to its true source—viz., inflammation arising from cold, it was incidentally stated that the subject of the case "was imprudent enough to expose himself by dining out with a party of pleasure on an adjoining island, when he drank freely of rum punch, and returned home at a late hour, exposed to the night air." This statement I beg now to withdraw, as I find a construction has been industriously put upon it which it was never meant to convey. It was not intended to designate an act of intemperance, of which the gentleman in question would be incapable, but simply to describe the imprudence of an invalid in participating in the enjoyments of the healthy, and such as, under ordinary circumstances, might have been perfectly unobjectionable as well as compatible with the accepted rules of temperance and propriety.—I am, sir, your obliged servant,

RICHARD FAUSSETT, M.D.

Ballina, December 24, 1852.

### SHIRTS CUT BY MACHINERY.

WEBB AND CO.'S

New System of Shirt-cutting by Machinery enables them to produce really First-class Shirts at prices lower than they have ever yet been offered.

Their Eglinton Shirts,

at 2s. 6d., 3s. 6d., and 4s. 6d. each,

are accurately Cut, elegant in Design, and perfectly sound in Fabric.

A large assortment of Fancy Veined Full-dress Shirts always on hand.

### THE TAILORING AND GENERAL OUTFITTING WAREROOMS

are now most extensively supplied with every description of WINTER CLOTHING.

### THE READY-MADE DEPARTMENT

contains an immense variety of

Top Coats, Travelling Coats, Wrapper Coats, Pilot and Frieze Pea Coats,

at 15s., 17s. 6d., and 20s. each,

which, for Workmanship and Solid Value, are not and cannot be surpassed.

WEBB AND CO.,

10, 11, and 12, CORN-MARKET.

Now ready, cloth, 8vo, pp. 346, price 9s.,

### SYPHILITIC DISEASES:

Their Pathology, Diagnosis, and Treatment, including Experimental Researches on Inoculation, as a Differential Agent in Testing the Character of these Affections.

By JOHN C. EGAN, M.D., M.R.I.A.,

Fellow and Licentiate of the Royal College of Surgeons in Ireland; Member of Council of the Surgical Society of Ireland; formerly Surgeon to the Westmorland Lock Hospital, &c. &c.

London: John Churchill, Princes-street, Soho.

Dublin: Fannin and Co., Grafton-street.

### NEWSPAPER FOR THE FARMING AND GARDENING INTEREST.

January 1, will be published, price Sixpence, free by post, each volume complete in itself,

*Enlarged to twenty-four folio pages,*

The First Number for 1853, of the  
**GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE;**

A Weekly Record of Rural Economy and General News.

*The Horticultural Part Edited by Professor Lindley.*

The Farming Part (under the Editorship of a Practical Farmer) treats of—

<p>The Practice of Agriculture, Agricultural Science, Animal and Vegetable Physiology, Improvements in Implements, described by Woodcuts whenever requisite, Better modes of Husbandry, Results of Experimental Farming, Growth and Rotation of Crops,</p>	<p>Management of Stock, Veterinary Science, Drainage, Irrigation, Forestry, Road-making, Farm-buildings, Labourers, Treatment of Poultry, Agricultural Publications.</p>
--	--

In short, whatever affects the beneficial employment of Capital in Land.

Reports are regularly given of the English, Scotch, and Irish Agricultural Societies and Farmers' Clubs—London Market Prices of Corn, Hay, Cattle, Seeds, Hops, Potatoes, Wool, Coal, Timber, Bark, &c., and the Weekly Averages.

As regards the Gardening Part (under the Editorship of Dr. Lindley), the principle is to make it a weekly record of everything that bears upon Horticulture, Floriculture, Arboriculture, or Garden Botany, and such Natural History as has a relation to Gardening, with Notices and Criticisms of all works on such subjects. Connected with this part are

*Weekly Calendars of Gardening Operations,*

Given in detail, and adapted to the objects of persons in every station of life; so that the cottager with a few rods of ground before his door, the amateur who has only a greenhouse, and the manager of extensive gardens, are alike informed of the routine of operations which the varying seasons render necessary. It moreover contains Reports of Horticultural Exhibitions and Proceedings—Notices of Novelties and Improvements—in fact, everything that can tend to advance the profession, benefit the condition of the workman, or conduce to the pleasure of his employer; Woodcuts are given whenever the matter treated of requires that mode of illustration.

Replies to Questions connected with the object of the Paper are also furnished weekly.

Lastly, that description of Domestic and Political News is introduced which is usually found in a Weekly Newspaper. It is unnecessary to dwell on this head further than to say, that the Proprietors do not range themselves under the banners of any Party; their earnest endeavours are to make the *Gardeners' Chronicle and Agricultural Gazette* a full and comprehensive record of facts only—a Newspaper in the true sense of the word—leaving the reader to form his own opinions: their object being the elucidation of the Laws of Nature, not of Man. The reader is thus furnished, in addition to the peculiar features of the Journal, with such information concerning the events of the day, as supersedes the necessity of his providing himself with any other weekly paper.

A Prospectus, with List of Contributors, may be had on application, or by letter, at the Office, 5, Upper Wellington-street, Covent Garden, London.

Parties intending to commence with the New Volume had better give their orders at once to any News-vender.

Just published, price 1s., by post, 1s. 6d.,

### A LECTURE ON THE WORKING OF "THE MEDICAL CHARITIES ACT,"

Pointing out its defects and the injustice done both to the Medical Profession and the Sick Poor by it as at present administered, and suggesting beneficial alterations and the best means of obtaining them.

By ANDREW ELLIS,

Fellow and late President of the College of Surgeons; Surgeon to the Royal Infirmary, Jervis-street; Professor of Surgery in the School of the Apothecaries' Hall of Ireland, &c. &c.

Dublin: Fannin and Co., Grafton-street.

### TO SURGEONS, DISPENSING CHEMISTS, ETC.

SULPHATE of QUININE, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, cap-suled, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.  
October 23, 1852.

*G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, Dublin, corner of Suffolk-street (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.*

*Superior Dissecting Instruments well worth the inspection of the Student.*

### THE COMPOUNDING DEPARTMENT AT

#### G. O. AND CO.'S MEDICAL ESTABLISHMENT

is separated from the Retail to prevent interruption and irregularity, and obtains the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be Supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

 Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

#### TERMS OF SUBSCRIPTION (PAYABLE IN ADVANCE).

### SURGICAL SOCIETY OF IRELAND.—Dec. 4.

Dr. HUTTON, President of the College, in the chair.

#### CASE OF DISLOCATION OF THE EYE.

By WILLIAM JAMESON, M.D., F.R.C.S.,  
Surgeon to Mercer's Hospital.

DR. JAMESON said he would detain the Society but for a very short time in detailing a case of dislocation of the eye which had lately come under his observation in Mercer's Hospital:—Peter Nowlan, *ætat.* 30, a powerfully able and muscular man, a corn porter, was admitted into Mercer's Hospital on the 3rd of November, at half-past twelve at night. His wife informed me that he came home that evening at ten o'clock in a most intoxicated condition, and while staggering about his room, struck his right eye against a small iron hook or nail that was in a dresser, which entered at the outer angle of the upper eyelid of that side, and when she went to his assistance discovered his eye protruded from its socket. She was most anxious to remove him at once to hospital, but could not succeed in prevailing on him to go until half-past twelve at night, when in a few minutes after this I saw him.

He was very boisterous and unruly, had a large check apron held close up to his eye, which he kept constantly rubbing and pressing against it. On its being removed, he presented a most peculiar, and I might add, frightful appearance. There was the right eye protruded out of the orbit, firmly fixed and immovable, staring, elastic to the touch, and devoid of all power of vision. The cornea was dry, cloudy, and rather opaque, pupil moderately contracted, and uninfluenced by the light of a candle. There was no extravasation of blood, nor was there any vascularity of the conjunctiva, although its reflection from the upper lid on the globe of the eye was partially torn through. The inferior margin of the upper lid was not visible, as it was placed behind the globe and spasmodically closed.

With difficulty I could get him restrained, as he was such a powerful man, but having accomplished it, I then, with two fingers of my left hand, elevated the upper lid, at

the same time, with the finger and thumb of my right, pressed the ball of the eye, and immediately it was drawn back with a distinct snap, and the lids closed over its anterior surface. I now, for the first time, observed the small wound before alluded to at the outer angle of the upper lid, but could not ascertain or form any conjecture at the time what amount of injury he might otherwise have sustained. I therefore had him conveyed to bed, and ordered cold to be assiduously applied to the part for the remainder of the night.

4th: The following morning, at visiting hour, we found him sober, but recollected little of what had occurred. His eyelids were a little swollen; there was some slight vascularity of the conjunctiva; the cornea was clear, shining, and moist, and the tears ran down the cheek; he could distinguish the day light; complained of pain in the head, and a deep pain in the globe of the eye, with full pulse. He was ordered to have *℥xvi.* of blood taken from his arm, bowels to be freely opened, and the cold to be continued to the part.

5th: Lids less tumid; pain and vascularity of conjunctiva almost gone; complains of the sensation as if gravel were between the lids; vision improved, but sees objects imperfectly, as through a thick haze. Ordered the tart. ant. mist., low diet, and the cold application to be continued.

6th: All pain gone; conjunctival vascularity less; sensation as if gravel were beneath the lids gone; vision nearly restored; has complete power over all the motions of the eye. Continue all.

7th: Convalescent; no suffusion; no pain; vision complete. 9th: Discharged cured.

The foregoing case I consider to be one of great interest, when we reflect on the novelty and nature of the accident, and the mode of its being inflicted. In the first instance, the great escape the orbital plate of the frontal bone had of being pierced, and consequent injury to the anterior lobe of the brain. Again, the length of time the cornea was left uncovered by the palpebræ, being two hours and a half, and all that time coarsely rubbed by the apron. The

great state of tension the optic nerve must have been kept in without permanent loss of vision. The escape the muscular attachments had of being torn from their origins, which evidently must have been the case from the subsequent perfect control retained over all the motions of the eye, as soon as the very slight amount of inflammation produced by the accident was removed. The powerful contraction of the orbicularis muscle behind the globe, with the complete restoration of vision. And finally, the trifling amount of constitutional disturbance and local inflammation that followed what appeared to be at first sight so very grave an accident to so very delicate an organ. These, I say, are points which add considerably to the interest of the case.

Dr. JACOB said the Society were greatly indebted to Dr. Jameson for the very interesting case he had just brought under their notice. As far as he could recollect, one of exactly the same kind was scarcely to be found on record. He thought it was a case which ought not to be dismissed from their consideration, without some suggestion to account for the occurrence of such an accident. He would solve the matter in this manner: Some persons were born with very large eyes and shallow orbits, and often, while examining the eyes of such persons, he found that by pressing the lids above and below, he could with ease get a view of the back of the eye. It was not that he merely saw one-half of the eye, but by a little manipulation of the eyelids, in persons with a shallow orbit and a large eyeball, he could obtain a view of the posterior part of the ball. Now, if by means of violence, the lids were tucked in above and below, they would grip the back of the eye and produce a downright protrusion of the organ from the orbit. He could not conceive any other way in which the accident could happen, because, as they might recollect, neither the muscles nor the optic nerve were torn in the case described by Dr. Jameson.

Dr. JAMESON.—The circumstance of the eye being drawn back with a distinct snap, shows that the muscles were at least on the stretch.

Dr. JACOB.—Yes, that is quite evident.

DECEMBER 18.

Dr. HARGRAVE, Vice-President of the College, in the chair.

ON POISONING BY THE BERRIES OF BELLADONNA.

By JOLLIFFE TUNNELL, Esq., F.R.C.S., M.R.I.A.

Mr. TUNNELL stated that two instances of poisoning by the berries of the atropa belladonna, or deadly night-shade, had a short time previously been admitted under his care into the City of Dublin Hospital, which he considered might prove interesting to the members of the Society and elicit discussion of a useful nature upon the active principles of this plant. He had accordingly brought notes of the cases, and would detail them to the Society.

The first was that of Thomas Penrose, ætat. 9, a stout, healthy-looking lad, who was brought to the City of Dublin Hospital, on Sunday evening, September 26, 1852, at seven o'clock, by his father, under suspicion of poisoning. He was violently delirious, laughing, dancing, and throwing his arms about, his eyes having a peculiarly wild and bright appearance, whilst the pupils were so much dilated, that the iris was only barely perceptible, as a fine ring or border round about. He continued grasping at imaginary objects, and crying out incoherently, not making use of any expression of suffering or uttering words relative to his being in the hospital, but pouring forth a string of incoherent broken sentences. He did not appear to recognize his father, or appreciate what was going on around him. The movements of his limbs were only partly voluntary, but the hand was constantly applied to the vertex, as if to remove something that was itching or annoying the scalp.

Upon questioning the father, he stated that the boy went away at noon for a walk, and returned about half-past three, when he sat down and appeared to be unusually silent. His father noticed this, and further remarked that there were small blisters round his lips. (These, on admis-

sion into hospital, had assumed the form of white spots upon the inside of the mouth and tongue.)

When questioned by the parent, he confessed to having eaten freely of some berries which he found lying on the pathway of one of the roads in the outskirts of the city. Shortly after he complained of soreness of the mouth and dryness of the throat, and subsequently became unsteady in his gait and confused in his ideas. Warm water was then freely given, and he vomited some gluey-looking matter, with three or four berries of a blackish red colour. Soon afterwards he became insensible, and was then conveyed to the hospital.

An emetic, consisting of a scruple of the sulphate of zinc, was administered by the resident pupil, Mr. Webb, on admission, the hair of the head was cut close, and the patient was put to bed.

On visiting him shortly after, I found his breathing slow and oppressed, but not stertorous; the pulse regular, 112; the surface of the body and extremities naturally warm. The zinc having had no effect, I directed an ounce of vinegar, with three ounces of tepid water, to be given to him, which he readily drank, and this to be followed by a second scruple of the sulphate of zinc.

Eight p.m.: The zinc was taken without producing any attempt at vomiting, and he seemed to be losing power. He was brought therefore to the edge of the bed, and a large can of very cold water poured over and upon the head. This caused much struggling and violent delirium for the while, but being followed by the admission of a continued stream of cold air, kept playing by means of a bellows on his head, he became more tranquil, and lay quiet, merely muttering and moving the hands about.

At nine o'clock, he had not improved, the delirium had returned again, and with more violence even than before. As there appeared to be no likelihood of the zinc acting, I introduced the stomach-pump, and injected forty ounces of tepid water, which, rushing up by the side of the tube, brought away much viscid matter, with a number of small brown, nodulated seeds, corresponding in character to those of the berry of the belladonna plant.

He suffered very little inconvenience from the use of the stomach-pump, and did not show signs of dyspnoea or distress, but the vomiting and evacuation of the stomach did not give relief. Two drops of croton oil and five grains of calomel were accordingly placed upon the tongue (for the insensibility had so increased that he could not be made to swallow), an injection of two drachms of sal volatile, with four ounces of water, was also thrown up the rectum, and the cold douche reapplied to the head.

Ten p.m.: No amendment; coma supervening; the extremities, hitherto warm, are now showing disposition to grow cold, and patient beginning to sink.

Mustard sinapisms were therefore applied to the posterior surfaces of either leg, a bucket of scalding water was sent for, and a blanket steeped in it. (This having been well wrung out, so as to be almost dry (a sheet in fact of woollen vapour), the patient was enveloped to the armpits in it. By half-past ten o'clock there was considerable change. The application of the scalding blanket has produced reaction; the face has become flushed, and the delirium again set in. Three leeches were accordingly applied to the right temple, and on their removal the use of the douche was resumed, each application being followed by the continued play of the cold air upon the head; the wet blanket also was removed, and a dry one substituted for it, in which he was tightly rolled, and the whole kept well in place by being bound round by a roller bandage, the jactitation of the limbs preventing any ordinary bedclothes from being kept on. The sinapisms were suffered to remain.

The following morning the delirium had decidedly decreased, and the pupils exhibited a trace of marginal iris, though totally insensible to the flame of a candle held close. Seven a.m.: Delirium and jactitation persistent; no sleep; no action yet from the bowels, the croton oil was therefore repeated, two drops being rubbed up with five grains of calomel and placed upon the tongue.

At nine o'clock a.m., he, for the first time, exhibited symptoms of consciousness, having put out his tongue upon being desired to do so, though the incoherent muttering and talking still continued. The countenance had a peculiarly wild and cunning expression; he looked as though he knew what was going on around him. The pulse had increased in frequency to 120, and was full; no urine had been passed since admission, and percussion over the pubis denoting the bladder to be distended, the catheter was therefore introduced, and some high-coloured clear urine drawn off.

Iced water was kept applied to the head, and a tepid foetid enema administered. A second foetid injection was thrown up at noon (the first not having acted), which produced a full copious stool, but having been removed by the nurse, I was unable to ascertain whether it contained any berries or not. The delirium continued until six p.m., when he fell into a quiet sleep, and awoke from it at midnight much improved, and the jactitation of the limbs diminished. The pupils were less intensely dilated, though still perfectly insensible to light.

On the 28th he was conscious, having slept the entire night, and awoke as from a dream, he having no recollection of what passed the day before, but referring all to the day preceding it. The bowels now acted freely, discharging dark copious stools, of moderate consistence, and the urine was passed easily, and of healthy character. He complained much of dryness of the tongue, with soreness of the throat and fauces; and upon examining the mouth, two oval spots of ulceration were visible (each about the size of a large letter wafer), covered with a tenacious yellow secretion, situated one on either side, at the commencement of the soft palate.

This condition appeared to have arisen from the contact of the croton oil, it having been left here after being applied to the tongue. The latter organ was morbidly clean, quite moist, and its papillae contracted. The pupils were scarcely less dilated, but he could discern objects; the pulse had reduced to 110; the calves of the legs were blistered by the mustard and hot vapour. He was ordered to take a couple of drachms of the acetate of ammonia solution in water every four hours, and for his diet some bland gruel. A solution of the nitrate of silver, twenty grains to the ounce, was applied to the ulcers of the mouth, and a solution of gutta percha in chloroform to the legs, with water-dressing by wet bandages outside.

On the 29th he was sensible, and could distinctly see objects at the end of the ward. The pupils, however, were still greatly dilated, and totally unaffected by light. When examined under sleep during the night, they were found considerably contracted. The tongue retained the same condition as yesterday, moist and soft, without a vestige of fur upon it. He was ordered to omit his saline medicine, and have good beef-tea thickened with arrow-root.

From this date he gradually improved, but for some days continued debilitated, and exhibited great languor; the countenance sunk, and the surface of the body having a dirty yellow, bilious tinge. The bowels acted during this time naturally, and though slow, his convalescence was unimpeded.

The legs were longer than usual in renewing the cuticle which had been removed by the sinapisms, owing to his having been scalded when an infant. The use of the gutta percha in chloroform as an application, answered very satisfactorily in this case. On the 11th of October he was discharged.

The second case was that of Joseph White, æt. 14, an intelligent-looking, well-made boy, brought to the hospital the succeeding day, September 27th, at two p.m., in a semi-conscious state, being unable to reply to questions put to him, or give any account of what he had been doing, but opening his mouth and exhibiting his tongue when desired. His eyes bore a peculiar bright appearance, wandering from side to side, and up and down, with the pupils intensely dilated, the limbs in perpetual jactitation, the motions partly voluntary, partly involuntary,

and very rapid. The delirium which accompanied this state had reference to his ordinary occupation—viz., that of a printer's boy. His pulse was 80, regular and soft. His father, who brought him to the hospital, stated that he had gone out for a walk at noon the day before, and returned home shortly before two: at three he dined heartily off bacon and potatoes, and at seven o'clock sat down to his evening meal of bread and butter, which he ate, but was observed by his mother to spill his tea. Her report is, that "he looked *stupid-like*, and shortly after she noticed that he slunk off, and went quietly to bed. He slept quietly until one a.m., when he got up and went about the house, apparently without any object, except that he would stoop down and pick, as if he was gathering straws. He next began to sing, laugh, and whistle, shaking every joint of his body, and dancing like one out of his mind."

His father attempted to quiet him, but without effect. He then gave him some whiskey, which did not appear to produce any alteration in the symptoms. He continued in the same condition up to noon, when some boys told him that his son had been eating poison berries the day before, on hearing which he brought him to the hospital.

He was put to bed, and the hair cut close, after which the cold douche was applied to the head. He was made to drink freely of vinegar and water, immediately upon taking which vomiting ensued, and he threw up the food ate on the preceding day in an undigested state, together with the husks or skins of a black shining berry, and a number of small brown seeds, which, under the lens, exhibited a nodulated appearance, like the top of an ordinary sewing thimble. With the vomiting, a marked alteration took place in the condition of the iris, the pupil becoming considerably more dilated than before.

A scruple of the sulphate of zinc was then administered, to secure full and perfect emesis, but no further effect was produced; an aperient, therefore, of croton oil and calomel was ordered to be taken, to ensure speedy clearance of the alimentary canal.

At two p.m., he was conscious to some degree, and could reply to questions asked, stating that he ate a number of red and brown berries the day before, after taking which he got scalding of the throat. Delirium now continued at intervals, and he became very restless, endeavouring to leave his bed, smiling, laughing, and picking at imaginary objects. Iced water was applied to the head, and a cold stream of air kept playing on the part, by means of bellows, through the night.

28th: He had slept soundly for some hours, and during this time the pupils were examined and found *as dilated as when awake*. He was much better this morning; quite conscious, though the motion of the extremities continued to some degree; the pupils as large as yesterday, and vision indistinct; one motion had taken place from the bowels; the throat was sore, and the fauces exhibited considerable redness, with slight ulceration of the tonsil; the dryness of the mouth and pharynx was much complained of. Cold applications continued to the scalp, an enema of turpentine administered, and a bland diet prescribed.

29th: He passed a good night, sleeping soundly; the pupils were examined several times, and on each occasion found contracted; to-day they were less dilated than yesterday, but still very large and barely moved on the application of light; the bowels acted frequently, and the urinary secretion was perfect, and voided without any difficulty; the soreness of the mouth and fauces had reduced, but the tongue had a very peculiar condition. It was moist and soft, and clean to a degree at the tip and edges, whilst running down the centre was a fur resembling a silver gray moss; the expression of the countenance that of languor, with a somewhat vacant look. Beef-tea and gruel were ordered for diet, with coffee at the breakfast and evening meal.

30th: The sensibility of the iris was now considerable, and the patient might be regarded as convalescent.

October 3rd: He was this day discharged from hospital quite well.

The quantity of berries eaten in this case was stated by

the boy to have been about as many as his hand would hold. He found them lying strewed along the footpath, as if they had dropped from a handkerchief whilst being carried along.

## REMARKS.

In relation to the foregoing cases, Mr. Tufnell said that there were some points of interest on which he would beg to offer a few remarks. The first was as to the frequency and fatality of poisoning by deadly night-shade. He believed of all the narcotic acrid plants it was the one whose fruit most frequently tempted children and others to partake of it, but occasionally the berries of the garden and the woody night-shade were also picked and eaten, as well as those of the daphne mezereum or spurge laurel. He found upon referring to the journals, cases recorded of poisoning by each of the plants that he had named, the fruit having been plucked by the individual, which was not however always the case, for in the autumn of 1846, several persons were poisoned in London, and two died from the effects of eating tarts made of the berries of the atropa belladonna or deadly night-shade, which were hawked about by a man named Hilliard, who sold them openly in the streets, believing them to be shoes. He was tried, however, for manslaughter, and convicted, his defence being that the offence was committed in ignorance, being unaware of the real nature of the berries, and that he had partaken of them himself as he went along. Now, in the cases detailed to the Society, death had very nearly ensued in one instance, and this owing to the negligence of some individual, for from the way in which the berries were found by these boys (lying strewed along the footway), it was evident they had been dropped by some party who was carrying them along.

As to the fatality attendant upon the swallowing of these berries, authors greatly differed. Thus, Haller was found saying that only three or four could be eaten without danger, whilst Christison mentions a case in which a pound were devoured by a lad, and recovered from, although medical treatment was not resorted to until next day. Age and constitution could alone determine the quantity that may be taken by any individual, as the cases then before the Society would prove; one lad, of nine years of age, being barely saved from death, although he had swallowed only a few, and been placed under active treatment within seven hours, whilst the other boy, of 14, had consumed upwards of a handful, and had had nothing done for him for a period of more than twenty-four hours.

Mr. Tufnell said he had spoken of three other kinds of berries as being sometimes eaten by children, and as having injurious effects—viz., those of the solanum nigrum or garden night-shade, the solanum dulcamara or woody night-shade, and the daphne mezereum or spurge laurel. The two former, as belonging to the order solanaceæ, had symptoms nearly allied to those of the belladonna—viz., giddiness, tremulous motion of the limbs, dilatation of the pupil, double vision, loss of sight, thirst, burning of the throat, convulsions, extravagant delirium, ending in sleep, and recovery, or coma and death. The other, the mezereum, as an acrid poison, causing burning of the mouth, exciting excessive vomiting and purging, creating great general irritation, convulsive movements of the limbs, and death by violent inflammation of the stomach and intestines; the pupils of the eye being contracted.

The uniformity of the symptoms of poisoning by the berries of the belladonna, were such as to render the diagnosis easy, and were well marked (Mr. Tufnell observed) in the cases he had read; and if enumerated, would be found to bear out the faithfulness of the description given by Dr. Taylor in his excellent work upon poisons. Thus: "Dryness of the throat and fauces, impaired vision, objects seeming double, and running backwards and forwards, suppression of the salivary secretion, inability to swallow from want of moisture, distressing sensation about the pharynx, great thirst, stumbling or staggering in walking, with giddiness and vertigo, eyes fixed, brilliant, and dazzling, pupils dilated to extreme degree, inability to hear or speak plainly, thoughts agreeable and vivid, with

fantastic spectacles apparent in the mind, a wish to be in constant motion, fingers perpetually in action, stomach and bowels indolent, neither vomiting nor purging taking place spontaneously, and rendering them almost insensible to medicine, attempts to get out of bed, followed by disposition to sleep." All these presented themselves more or less in both of the cases under consideration.

As to the treatment of poisoning by the berries of narcotic acrid and acrid plants, one main difference was found to exist. In the former there were extreme sluggishness, a torpor of the bowels; in the latter, irritability to a degree, vomiting soon after being swallowed, and diarrhoea at a later stage. Widely different treatment must therefore be had recourse to.

In poisoning by belladonna, then (or in fact any of the order of the solanaceæ), early vomiting was the first object to be produced. For this purpose, sulphate of zinc was in Peirce's case given, two doses of a scruple each, and no effect whatever produced; vinegar and water (as recommended by Dr. Thomson with the view of rendering the emetic effect more certain) was administered freely during the intervening time, and yet without emesis being induced. With this fact established, then, it became a question whether this was a practice to be recommended or not? Whether, in fact, the admission of acetic acid into the stomach upon the chewed berries was not likely, if retained there for any time, to extract the atropine or active principle of the plant? There could be no denying that in many instances the use of vegetable acids had been productive of the happiest results, lemon-juice, in poisoning with hyoscyamus, having frequently acted as an antidote, and in White's case, vomiting having ensued upon the vinegar's being taken prior to the administration of the sulphate of zinc. The guide in these cases as to the use of vinegar, must (Mr. Tufnell thought) be the stage of poisoning present—the state of the patient at the time. If, under the full influence of a narcotic acrid poison, when much torpor of the stomach might be expected, then to withhold its use, if suffering only to a slight degree, then to administer it, in conjunction with emetics, or alone, if other remedies were not at hand.

The stomach-pump, when procurable, should, in Mr. Tufnell's opinion, be resorted to without delay, if after a second dose of zinc or other emetic substance, free vomiting was not produced, of course premising that a stomach-pump could be procured. If it could not, and emetics failed, the practitioner had then to endeavour by croton oil purgatives, aided by injections, to expel the offending matters from the stomach and intestinal canal. Here, however, time was required for their action, in addition to the fact that the same influence which was presiding over the stomach was acting upon the muscular coats of the intestines, and preventing their peristaltic action being induced. It was necessary, therefore, to look round and see if any antidote for these vegetable poisons could be found possessing sufficient action to be desirable of adoption. Dr. Garrod, in the *Pharmaceutical Journal*, had written an article upon the use of animal charcoal as a successful antidote to vegetable poisons, its action being to combine with their poisonous principles, and render them innocuous. Dr. Garrod had tried it to some extent, and was satisfied with the results; using ivory-black digested in dilute hydrochloric acid, then washed and dried. This being triturated with warm water to the consistence of cream, was given to the patient, the quantity to be administered being in the proportion of half an ounce to a grain of the alkaloids, such as strychnia or morphia, or to a scruple of nux vomica or opium, the powders from which these alkaloids were made.

Vegetable charcoal he had also tested, but found efficacious only to a very small degree. The use of both kinds he found had the effect of neutralizing the emetic properties of ipecacuanha, as being a vegetable, but they did not materially lessen the action of sulphate of zinc. Charcoal, therefore, if employed in conjunction with vegetable emetics, must be subsequently to their use.

Tannin might also be tried, from its tendency to precipi-

tate the alkaloids, and if oak-bark and nut-galls were not procurable, a strong decoction of black tea might be tried.

The other remedies employed in the cases then before the Society, were cold affusion to the head, and stimulants to meet comatose tendency—viz., strong coffee given by the mouth, and ammonia injected into the rectum. There was another used in Penrose's case, which Mr. Tufnell could confidently recommend—viz., enveloping the whole body from the neck to the toes in a blanket wrung out of scalding water. In the collapse of cholera, he had found it rouse the vital powers when all else had failed; and it did more than this, for its sudden application to the surface arrested the serous drain which was running off from the capillaries of the stomach and bowels, the life blood of the patient.

It was an heroic remedy, and sometimes had the effect of removing the cuticle from the calves of the legs and nates, and other convex portions of the body, and was not therefore to be unnecessarily employed, but in fitting cases would be found a very valuable agent. In the instance, then, before the Society, sensibility had ceased, the vital powers were fast failing, and the extremities had grown cold, yet by its application the patient was brought round.

There was only one other point to which he would allude, but this, in a physiological point of view, was of great interest—viz., the action of the iris during sleep, and the relative difference in the condition of the pupil at that period and when awake, in persons poisoned by belladonna. Attention to this fact had first been called by his colleague, Professor Geoghegan, and to its accuracy he could attest, as he had visited both patients in the middle of the night for the special purpose of noting this point, and had found in each instance a marked diminution in the size of the pupil and degree of contraction from what existed when the patient was awake. So far as Mr. Tufnell was aware, he believed that under the ordinary local application of this agent (for the purpose of dilating the pupil for operation, or in iritis), the radiating fibres continue to act, and keep the opening enlarged during sleep, as when awake.

The President said the cases just introduced to their notice were of a most interesting character, and had been detailed with very great accuracy in Mr. Tufnell's valuable communication. Some points were suggested by the paper that deserved the attention of the Society, and one of these was the peculiar fact of the iris being dilated almost to annihilation, when the patient was awake, and being contracted during sleep. If his memory was correct, there was but one other case on record of poisoning by belladonna where the iris was contracted during sleep.

Dr. Jacob said the general impression upon his mind was, that contraction of a pupil artificially dilated could not exist during sleep. When children are brought to him with cataract, he drops a solution of the nitrate of atropa into the eye, and in the course of half an hour finds the infant asleep, and the pupil fully dilated; but on no occasion has he observed it to contract again. He thought that no more interesting or remarkable physiological phenomenon presents itself to the physician than the unaccountable one of the dilatation of the pupil by means of belladonna. They might say, if they pleased, that it paralyzed the sphincter, or stimulated the dilating muscle; but what, he would inquire, was the local influence which operates in this manner? He (Dr. Jacob) had been astonished at the amount of ignorance he had seen displayed by medical men with reference to the effects of this poison (for a poison it certainly was) upon the iris. There seemed to be growing up a queer notion that a considerable difference existed between the action of a common solution of belladonna and that produced by atropa, which, he might observe, was the product of the extract itself. Now, it was plain that when they used a solution of belladonna, the dilatation was due to the presence of atropa, unless it could be shown that two distinct agents were present capable of producing the same effects. It was downright nonsense to assert that atropine had any different action from extract of belladonna. True, it was

a very convenient application; but they must not forget that when they dropped a solution of the extract of belladonna into the eye, they were in point of fact using a solution of atropa; and yet, with a knowledge of this obvious fact, it was announced in books that somebody had made the discovery of the dilatibility of the pupil by atropa. He used sometimes the atropa and sometimes the common extract of belladonna. One grain of this salt dissolved in an ounce of water would be found sufficiently strong to dilate the pupil. It had been said that when atropa was applied, the pupil would not contract for seven or eight days. This was true in the case of some young people, in whom the effect continued for a length of time, but in other instances the pupil would contract in twenty-four or forty-eight hours, whether they used the one preparation or the other. With respect to the alleged influence of atropa or belladonna extract on muscle, or that it acted on the sphincter ani or uterus, he (Dr. Jacob) was firmly convinced that no well-authenticated fact could be adduced to prove that belladonna exercised any such influence. They had before them the fact that when they dabbed the brow with it, although the pupil was dilated, the orbicularis palpebrarum remained entirely unaffected. He was induced to throw out these few remarks, not because they were intimately connected with the cases before the Society, but because the subject was one that required further investigation, involving, as it did, questions of the highest importance, both in a physiological and pathological point of view.

The President said he fully concurred in the remarks which fell from Dr. Jacob as to the circumstance of belladonna not exercising any influence on the sphincter ani muscle. He had often used it himself for that purpose, and in no instance whatever did it produce the desired effect.

Dr. FLEMING said, that not having been present whilst Mr. Tufnell was addressing the Society, it might be thought unreasonable, on his part, to offer any remarks upon the interesting subject under discussion. Perhaps, however, he might be allowed to do so, inasmuch as observations, with respect to the use of belladonna, as a therapeutic agent, might to a certain extent enable them to satisfy themselves respecting the physiological effects consequent upon its application medicinally, and the results of its administration as a poisonous agent. Belladonna had been used both in medicine and in surgery: in medicine, principally, he believed, in the advanced stage of pertussis or hooping-cough; in surgery, both locally and generally; locally, in reference to some particular affections at the lower part of the anus; and it had been strongly recommended by the late Baron Dupuytren in those cases, which implicated the action of the sphincter muscle, with or without fissure of the anus. Now, he (Dr. F.) had used the preparation of belladonna recommended by this gentleman, and as far as his limited experience went, it did not produce relaxation of the sphincter muscle in that satisfactory manner which he had been led to expect. In one instance, which came under his observation, a decidedly specific or poisonous effect resulted from the application of the ointment within the verge of the anus, and in other cases vision was impaired, and delirium, with other unpleasant symptoms, made their appearance. In these cases he took care to examine the condition of the pupils, and in every instance they were dilated to a remarkable degree; but it did not occur to him, at the same time, to watch the state of the pupils during sleep. It was, however, a curious fact, and he thought Dr. Jacob would bear him out in the assertion, that the dilated condition of the pupils would remain even after the specific agent had been discontinued, sometimes for days together. He had met with cases where the pupil remained dilated (more frequently after the use of the solution of atropine) for two, three, and four days, to the great annoyance of the patient, and he believed that this state of the pupil was more likely to continue after the use of the atropine, than after the application of the simple extract of belladonna. The atropine appeared to possess this advantage in ophthalmic surgery—that its

effect was produced within an incalculably short space of time. Within ten or fifteen minutes, the pupil would, in all probability, be fully under the influence of a solution of atropine, dropped into the eye. But as far as his experience went, full dilatation of the pupil would not be produced so rapidly—by the external application of the extract of belladonna—by its internal application inside the eyelid—or by the employment of the well-known collyrium (containing belladonna) used in hospital practice, the strength of which was about one grain to an ounce of water. The internal use of belladonna was now freely recommended in cases of traumatic tetanus. On a late occasion, he gave it in a case of this kind, but its administration was followed by almost poisonous effects, the patient being a child, not more than three years old, who was sent to the Richmond Hospital. The age of the patient was a peculiar feature of this case; for it was very rarely that traumatic tetanus occurred at this early period of life. A thorn or nail stuck in the sole of the foot, and the symptoms of traumatic tetanus set in at so late a period as five weeks after the receipt of the injury. Under these circumstances, they would know how, within certain limits, to estimate the value of the remedies they employed; because the later the supervention of the disease, the more likely was Nature herself to succeed in curing it, or at least the more likely were the remedies to produce a favourable effect. Having heard Dr. Hutton (upon whose experience he placed the greatest reliance) state that he found belladonna extremely serviceable in cases of traumatic tetanus, he (Dr. F.) resolved to give it a trial in the case of this child. The preparation he used was the extract, and the menstruum, water. The quantity was two grains of the extract in two ounces of water, and at first he only gave the sixteenth part of a grain every second hour, the amount being subsequently increased to the eighth, and finally to the sixth of a grain. It did not appear to produce any visible effect in the first instance, but when he increased the dose to the sixth of a grain, he observed that although the symptoms diminished in frequency, they had positively increased in intensity; and he was, at the same time, struck by the uncomfortable and irritated condition of the child; which became so unmanageable that its mother could scarcely control it. Some effect was produced on the pupils, but not to the extent of dilatation; and there was an eruption on the skin, closely resembling that of scarlatina, which he attributed to the action of the belladonna. The effect of the belladonna in this case was, therefore, to control the frequency, but not the intensity of the fits.

Dr. BAGOT wished to offer one remark upon that part of Mr. Tufnell's paper which related to the non-action of the sulphate of zinc, used as an emetic. It was a matter of much importance to possess some medicine which would act suddenly and efficiently as an emetic, in cases of narcotic poisoning. Having tried the sulphate of zinc in a great many instances, he must confess that it did not act satisfactorily as an emetic. It was stated in books, as well as in lectures, that it was an exceedingly rapid emetic; but according to his own limited experience, it was quite the reverse; for he had seldom known it to act in a shorter time than ten or fifteen minutes, and he could mention instances in which, being administered to patients suffering from poison, it failed altogether in producing the desired effect. He remembered trying it in the case of a gentleman, on whom he wished to produce very rapid vomiting; but though he gave him a scruple of the sulphate in the first instance, and afterwards half a drachm, vomiting did not follow. In order to produce rapid emetic action, he had lately employed a combination of hippo and mustard, with very considerable success. Eight or ten grains of hippo, with one teaspoonful of mustard, would be found in many cases to act with sufficient rapidity, yet in such a manner as not to produce much prostration of strength.

Dr. JACOB, in reply to Dr. Fleming, repeated his conviction that there was no difference, except one of strength, between a solution of belladonna and a solution of atropa. If they put two grains of the nitrate

of atropa into one ounce of water, or dissolved one drachm of the extract of belladonna in a similar quantity of water, they would find that the action of both solutions was precisely and necessarily the same. A grain of the one or a drachm of the other would be strong enough to dilate the pupil, but two grains or two drachms would be sufficient for all purposes; the dilatation, however, would not take place in ten minutes: he had seldom known it to occur so early as a quarter of an hour after the application of the atropa or belladonna, and in the generality of cases, half an hour was required for the purpose. It was said that dilatation of the pupil was not attended with a defect of vision, but he (Dr. J.) knew very well, having tried the experiment on himself, that it would cause a temporary defect of vision, which, however, usually disappeared in the course of the following day. In his own case the dilatation lasted twenty-four hours, the pupils contracting again after a night's rest.

## IODINE INJECTION OF THE JOINTS.

By M. VELPEAU.

AMONGST the affections of the joints, effusion into them is a very common affection, but is only serious as a symptom of the disease which accompanies it. When it occurs as a serous interarticular effusion, without any marked material lesion, recent hydrocs articuli is easily cured by rest, bleeding, and topical applications, such as solutions containing muriate of ammonia or chloride of sodium. When the effusion resists these means, M. Velpeau applies a large flying blister, repeated every fifteen days, and then uses frictions with mercurial or iodide of lead ointment (the latter being preferable to the iodide of potash), aided by compression, the administration of calomel in small doses, and especially rest. There is another remedy now used—namely, the injection of tincture of iodine. M. Velpeau has only tried it twice this year; but from these two cases, it is plain that the injection thus used is neither very painful nor dangerous, and that when thus cured, the joint is not ankylosed. In one very bad case particularly, the injection was not more painful than when used for the cure of hydrocele, and succeeded where the other means referred to had failed. It is necessary that the treatment by iodine injection should be made more generally known, as it is not usually practised. The two points which deter surgeons from using it are, the fear of throwing an irritating fluid into a large joint, and of ankylosis taking place in case of success.

Now, both these dangers are imaginary. There is no previous incision, but a simple puncture made. Since 1839, M. Velpeau has used this plan twenty-five times. M. Bonnet perhaps as often, so that with cases of the same kind, related by Berard, and since, by M. Jobert, Maligne, and other surgeons, there are more than one hundred cases of these joints having been punctured and treated by the iodine injection, and none of the patients have had any unfavourable symptom. The swelling, with slight redness, which appears after the operation, only shows that a natural process is going on, such as takes place in a hydrocele, and is resolved without the application of leeches, &c.

As to the danger of ankylosis, it is equally imaginary. M. Velpeau has seen these patients long after the operation, and in all the movements of the joints were preserved. It is, in fact, in these cases, as in hydrocele, the cure can be effected without the obliteration of the serous sac; or if adhesions do take place, they yield after a time, and the function of the joint is restored, so that this is no serious objection; and, as on the other hand, there is complete cure in one-half the cases, and very marked amelioration in the other, it is to be concluded that the iodine injection, under such circumstances, when as yet there is no induration, is suitable, and the more so, as its use does not prevent that of other accessory means of cure.—*Presse Médicale de Belge.*

ON  
SOME OF THE MORE IMPORTANT CHEMICAL  
DISINFECTANTS.

By GEORGE WILSON, M.D., F.R.S.E.,  
Hon. Member of the Pharmaceutical Society of Great Britain.

I CONSIDER it an acknowledgment due from me to the Pharmaceutical Society of Great Britain, which has honoured me with its diploma, that I should contribute a paper to the proceedings of its Edinburgh section, with which I stand more immediately connected. I have selected a subject, of special interest at the present moment, when we have reason to apprehend the appearance of cholera on our shores, but which is at all times a subject not less important than it is difficult. To discuss the entire question of disinfection would require many papers. I can only refer at present to some of its relations.

The term *disinfectant*, in strictness of language, can only be applied to those agents or substances which destroy or decompose infectious or contagious matter. But it is usually employed in a wider sense, so as to include, not only *disinfectants proper*, but likewise *antiseptics* and *deodorisers*. Any attempt to draw a sharp line of demarcation between these three classes of agents, is rendered impossible by our almost total ignorance of the nature of contagious matter. Some substances, such as chlorine and sulphurous acid, possess at the same time, disinfectant, antiseptic, and deodorising powers. Some, like common salt, are probably simply antiseptic, of others, such as the salts of the heavy metals, which are in high repute as deodorisers, it may be questioned whether they are of any value as disinfectants, although with some persons they rank at the head of the list. Without insisting at present on this, it may suffice to define the bodies we are about to consider, thus: A disinfectant is an agent which effects the chemical decomposition of organic poisonous matter—the term poisonous being used in a wide sense to include all the known or supposed causes of the development of disease, which are referred to under the names of miasma, malaria, infectious virus, contagious matter, &c.

An antiseptic is an agent which prevents or arrests the development of organic poisonous (or non-poisonous matter) without effecting its chemical decomposition.

A deodoriser is a substance which destroys odour, by decomposing or combining with, or absorbing odorous matter. Chlorine, for example, decomposes sulphuretted hydrogen, whilst a salt of lead decomposes it, and charcoal simply absorbs it.

Before considering the relative merits of particular substances belonging to these classes, it is necessary, however, briefly to discuss the important question—does the poisonous organic matter which occasions certain diseases, occur in the solid, liquid, or gaseous form? The certainty that prolonged exposure to a vitiated atmosphere, such, for example, as that of a fever ward, produces disease, has led to a conclusion in which probably all concur, that the air is one of the chief media through which disease is propagated, and this connexion has in turn led to the much more doubtful inference that infectious matter is truly gaseous or vaporous. This view has probably been strengthened by the recent extensive study of the properties of anæsthetics, and by the many observations which have been made on the rapid and powerful action on the body of substances which enter it through the lungs. It has certainly also been deepened by the opinion, widely prevalent, that the gases which are evolved from cesspools, sewers, and stagnant waters in general, particularly sulphuretted hydrogen, hydrosulphuret of ammonia, and marsh gas (light carburetted hydrogen) are the *direct* and *specific* causes of ague and fever.

If this opinion were well founded, the limits and best modes of applying disinfectants could be determined without much difficulty, and our control over infectious diseases would certainly be much greater than it is.

I think, however, that we may with confidence affirm that the great majority of diseases are not propagated by

gaseous poisons. The recent tendency to advocate an opposite opinion, has been mainly occasioned, I believe, by an opinion expressed by the late Professor Daniell to the effect, that the fatal fever of the African coast is occasioned by sulphuretted hydrogen. This view was founded on an analysis of water brought from that coast, and determined the ventilating arrangements fitted up in the vessels which formed the disastrous Niger Expedition. It appears to have been extensively adopted by medical men.

During the frequent prosecutions for nuisance, under the new police act, which took place in this city and elsewhere, during the last visitation of cholera, it occurred to me, and to other chemists, to be constantly met by endeavours on the part of the prosecutor to compel an acknowledgment that sulphuretted hydrogen, hydrosulphuret of ammonia, and marsh gas or light carburetted hydrogen, which are confessedly given off by sewage waters, are the *direct* causes of fevers and other diseases. So long as this idea prevails, and men rest satisfied with it, as the true explanation of the mode in which fevers and similar maladies originate and are disseminated, they will cease to prosecute inquiry into the matter. It is most important, therefore, to discountenance the notion that we are acquainted with the true *materies morbi*.

That neither sulphuretted hydrogen nor hydrosulphuret of ammonia produces any special disease, may be sufficiently demonstrated by the impunity with which persons are known to expose themselves to much larger quantities of these gases than can possibly act on those who suffer from exposure to marsh miasmata. In these, the nicest tests have failed to give the slightest indications of sulphuretted hydrogen, and yet a few hours exposure to such miasms has been enough to develop fever. On the other hand, in every analytical laboratory, sulphuretted hydrogen and hydrosulphuret of ammonia are daily respired for weeks or months together by those engaged in analysis, yet analytical chemists certainly are not specially subject to fevers. At the Bonnington Chemical Works, where the ammoniacal liquor from the Edinburgh Gas Works is largely converted into sulphate and muriate of ammonia, the workmen are exposed to the hydrosulphuret of ammonia which forms so considerable a part of the liquor, and when it is neutralized with sulphuric and muriatic acid, sulphuretted hydrogen is given off in such abundance as to blacken the silver coins and watches on the persons of the bystanders, and even (along with the carbonic acid simultaneously evolved) to render them temporarily insensible if they incautiously respire the gases. Yet no special malady is known to result from this exposure, and the Bonnington Works enjoy the reputation in the neighbourhood of protecting it from the inroads of endemic and epidemic diseases. Similar observations as to the non-deleterious effects of exposure to comparatively large volumes of sulphuretted hydrogen have been made at the metal works, where a superficial tarnish of metallic sulphuret is removed by washing with acids, and the workmen are freely exposed to the sulphuretted hydrogen evolved. I need not say, that I do not wish to affirm that this gas or its combination with ammonia, is not a powerful poison, if respired alone, or to deny that the continued entrance of either into the body, must debilitate it and prepare it for yielding to the attacks of disease. But that it is the cause of the fevers, which a very short exposure to the so-called malaria of certain districts infallibly occasions, I altogether disbelieve.

The alleged noxiousness of diluted marsh gas (light carburetted hydrogen), admits of more easy disproof, for were it the deadly agent it has been declared to be, our colliers who are exposed in coal pits to much larger volumes of it than any other class of persons, should be to a corresponding extent sufferers from the diseases which it is supposed to occasion; but unless when its mixture with air explodes, it is destitute of any injurious action on the pitmen, who are a healthy class of the community.

Another disease—namely, influenza, has been imputed by high chemical authorities to the diffusion through the atmosphere of a peculiar gas. Dr. Prout regarding sele-niuretted hydrogen as its cause, Schönbein attributing its

production to ozone. There is no evidence that either of these views is true, but much may be said in favour of the latter. The last severe epidemic of influenza spread over Europe with a rapidity which almost seems to point to a gas as the medium of its propagation. No one, however, has detected seleniuretted hydrogen in the atmosphere; and air largely impregnated with ozone may be breathed with an impunity which throws grave difficulties in the way of Schönbein's hypothesis.

Whilst thus, with the exception of influenza (if it is to be excepted), no gas is known to possess the power of developing an infectious or contagious epidemic or epidemic; on the other hand, as Professor Graham has justly remarked, such infectious matters as are accessible to us; for example, the matter of cow-pox may be dried in the air, and is not in the least degree volatile. Indeed, the volatility of a body implies a certain simplicity of constitution and limit to the number of atoms in its integral particle, which true organic bodies appear not to possess. Again, the source of such bodies being, at all times inconsiderable, they would, if vapours, be liable to a speedy attenuation by diffusion so great as to render their action wholly inconceivable. It is more probable that matters of contagion are highly-organized particles of fixed matter, which may find its way into the atmosphere, notwithstanding, like the pollen of flowers, and remain for a time suspended in it.\*

To these statements it may be added, that all chemists now acknowledge that volatility is not essential to the transference of solid bodies to the atmosphere, at least so far as those soluble in water are concerned; for observations on the largest scale have shown that the vapours of volatile liquids carry with them sensible quantities of all the solids which they dissolve; common salt, nitrate of potash, boracic acid, phosphoric acid, afford marked examples of this; but the list of salts soluble in water which accompany its vapour at temperatures at which when dry they are fixed, is endless.\* The significant word "*Malaria*," therefore, which embodies in a single term, the evil reputation which the air or atmosphere has acquired, as the vehicle of contagion, may still, if we choose, be retained, although we acknowledge that all accessible contagious matters are non-volatile liquids or solids. It may further be added, that with the questionable exception of influenza, no endemic or epidemic spreads with the rapidity and equability, so far as area of occurrence is concerned, which would characterize it, if it were occasioned by a gas subject to a force so powerful as that of gaseous diffusion. Professor Graham's argument is still more cogent, for, according to his views, if infectious matters were truly gaseous, we should never have endemics or epidemics, unless those matters were developed in immensely larger quantities than by universal acknowledgment they are. In truth, they elude every test, even when applied to large volumes of the most infected atmospheres.

From all that has been stated, it must be inferred, according to our present knowledge, that at least the great majority of the substances which are intended to be reached by disinfectants, are not volatile, and therefore are much less easily decomposed than if they were gases. We may also with reasonable confidence affirm, that they are organic products, and as such consist of carbon, hydrogen, oxygen, and nitrogen, or at least of two (if not always of three) of these elements; and that like all such compounds, they are readily decomposed by chemical reagents, especially oxidizing ones. There is no reason to imagine that infectious matters are difficult to decompose, *provided we can reach them*. The difficulty lies in reaching them. Assuming then that contagious matters are not volatile, and that they

contain (to take the most complex case) carbon, hydrogen, oxygen, and nitrogen, the principles which are to guide us in the application of chemical disinfectants, will not be far to seek. Oxidizing agents will plainly be of great value as they can readily convert hydrogen into water, and carbon into carbonic acid, and thus disintegrate and destroy the morbid matter. Substances having a great affinity for hydrogen, such as chlorine and its class, will plainly also be of great service. Substances having an affinity for oxygen will also be applicable to the destruction of organic poisons; and, finally, all reagents which by contact with organic matter can determine a new arrangement of its ultimate elements. All the powerful chemical disinfectants act in one or other or all of those ways. I shall refer to five of the disinfectants: 1. quicklime, 2. sulphuric acid, 3. potash and soda, 4. nitric acid, 5. chlorine, 6. aqua regia, 7. ozone. The value of *quicklime* and of the *caustic alkalis* as disinfectants, has certainly not been overrated, although it may be questioned whether our sanitary authorities have been wise in trusting to lime alone as a purifier. From the careful study of the process of natural and artificial nitrification, and from the results of the application of soda lime in organic analysis, we have learned that the caustic alkalies and alkaline earths decompose organic matter with the evolution of ammonia, which by oxidation may become converted into nitric acid. Woodwork or stone floors, to which a coating of limewash cannot be applied, requires only to be washed with caustic soda or soft soap, to obtain an effect identical with that which lime occasions.

2. *Nitric Acid* seems latterly to have fallen into disrepute, but certainly undeservedly. It acts more rapidly on many organic compounds than chlorine does, attacking their carbon as well as their hydrogen, and as it is not required in large quantity its application is not costly.

3. *Chlorine*.—Of chlorine, which is at present the favorite disinfectant, it is needless to speak. Its peculiar power of decomposing combinations of hydrogen, gives it, in one respect, a superiority over nitric acid, which does not decompose many of the gaseous hydro-carbons; but it should not be forgotten that it is only in the presence of light that this action of chlorine is fully displayed, so that its disinfectant influence is comparatively small in the case of dark or ill-lighted apartments, such as underground cellars, the lower cabins, or the hold of a ship, which are the very places where disinfectants are often most wanted.

4. *Aqua Regia*, as uniting the properties of nitric acid and of chlorine; each of which has peculiar virtues, the former in particular being a powerful oxidizing agent, the latter possessed of a great decomposing action over hydro-carbons, appears entitled to a high place among disinfectants. It can be cheaply procured by pouring oil of vitriol on a mixture of nitre and common salt, or by heating a mixture of nitric and muriatic acids.

One of the most rapid and effectual methods of disinfecting a large empty apartment such as an hospital ward, would be to place in one corner a vessel containing the materials for chlorine, such as oxide of manganese and hydrochloric acid, or oxide of manganese, common salt, and oil of vitriol; and in another corner a vessel containing nitric acid and a few fragments of copper, so as to evolve nitric oxide, which would spread through the apartment and form nitrous acid there, oxidizing everything oxidizable which it contained, whilst the chlorine specially attacked the hydro-genous compounds. The walls might then, if necessary, be lime-washed, with a view alike to destroy any adhering organic matter which had resisted the action of the gases, and to neutralise any traces of free acid.

5. The last of the disinfectants proper to which I refer is the singular substance ozone, which has a special interest, as being in all probability the great natural disinfectant. Its nature is still matter of speculation. Schönbein, its discoverer, regards it as a peculiar oxide of hydrogen; Berzelius and Faraday represent it as simply oxygen in a peculiar (or allotropic) state of modification; it has been suggested that it is an oxide of nitrogen; and quite recently M. Fremy has affirmed it to be what he calls "elec-

\* In virtue of this we may anticipate the administration of other medicines than anæsthetics by the lungs, although they may not be volatile. In cases of poisoning it would be of the greatest importance, if we could directly transfer to the blood an emetic or purgative, which we may hope to do along with the vapour of its solvent, aqueous or non-aqueous. Such a process, however, would be applicable only to medicines which act powerfully in small doses.

trized oxygen,"—i.e., oxygen modified in properties by the action of electricity upon it; a view not materially differing from that of Berzelius and Faraday. There are difficulties in the way of all these views, into which it is not necessary to enter. All that concerns our present subject is that, by different processes a substance can be developed in the atmosphere which possesses remarkable disinfectant and oxidizing properties. The oldest known method of producing the so-called ozone, is the exposure of air to a stream of friction or high tension electricity. Its odour may always be recognized in the neighbourhood of an electrical machine whilst at work. Another method is the galvanic decomposition of water, when the ozone accompanies the evolved oxygen. A third, and the most convenient method on the small scale is the exposure of phosphorus in moist air. By these processes and by certain others, air is made to acquire a striking power of oxidizing, bleaching, deodorizing, and disinfecting. We cannot doubt that every thunder-storm develops some ozone, and other processes also probably produce it. At all events the atmosphere frequently exhibits an oxidizing and bleaching power, at other times absent, which Schönbein, Faraday, and others, attribute to the development of ozone within it.

No one who has experimented on ozone will doubt its potency. I refer to it here because there are so many reasons for believing that it is the agent which prevents the accumulation in the atmosphere of volatile organic bodies, by converting them into water, carbonic acid, nitric acid, and ammonia, that we cannot avoid looking hopefully to it as destined to prove our disinfectant *par excellence*. Certain as we are that for thousands of years miasmata, malaria, poisonous effluvia, and every gas, vapour, and volatile body developed at the surface of the earth, must have found their way into the atmosphere, and that nevertheless its purity is not sensibly affected, we must regard the constituent or condition of the air, which has secured its purity during centuries, as one demanding special study. Further this constant process of disinfection has not interfered with the respiration of animals, so that we may fairly regard ozone as a substance applicable as a disinfectant in places occupied by human beings or by the lower animals. It is true that the power of producing influenza or catarrh has been attributed to ozone in excess; on grounds, however, almost entirely speculative. This view may or may not be true; but of this I am quite certain, that the well-known impunity with which electricians expose themselves for hours together to the action on the atmosphere of large friction machines, which the dullest nostril can discover to be producing abundance of ozone, is enough to show that a large impregnation of the air with this substance, neither affects respiration nor produces catarrhal affections. We ought, therefore, I think, to give special attention to ozone. It is not likely that we shall be long without discovering new processes for its production. It will be specially valuable for what are the most important, and, at the same time, the most difficult occasions for disinfection—namely, where human beings cannot be removed from infected apartments. Examples of such cases are found in a large ship at all times, and still more when its crew and passengers are attacked by disease; in the wards of an hospital, from which the sick cannot be taken; and perhaps most strikingly in a large factory, where hundreds of persons assemble daily together, many of most uncleanly habits, and at epidemic seasons fresh from infected rooms, whilst the apartments contain valuable metallic machinery, and fragile silk, cotton, linen, or woollen goods, which interpose an additional obstacle to the free employment of gaseous disinfectants. The condition of our ships as regards ventilation and wholesomeness is proverbial; and on inquiry of residents in Manchester and Glasgow I find, that where disinfection has been attempted in factories—which it rarely has—it has consisted in sending a man once a day through every room with a quantity of blazing pitch, which was supposed to fumigate into purity the atmosphere, whilst it set all the workpeople coughing.

How difficult it is to prevent the spread of erysipelas,

gangrene, fever, and the like in hospitals, every medical man knows too well. Ozone at least deserves a trial as a disinfectant in such cases.

*Antiseptics.*—The only antiseptics to which I shall refer are two. The first is sulphurous acid: it is a powerful antiseptic, for it resists thoroughly the decomposition or decay of organic matter. In reality, however, it as much resists the development as the decay of organic bodies, and thus it doubly prevents the evolution of organic poisons. Dr. Christison long ago pointed out how small a quantity of this acid is sufficient to destroy plants. In the wine countries it has been used from time immemorial to prevent the souring or acetification of the lighter wines, when kept in casks partially filled. Professor Graham, who strongly recommends it as a disinfectant, draws attention to the fact that at Manchester the offensive effluvia of the cochineal dye-vats, which resist the action of chlorine and nitric acid, are at once destroyed by sulphurous acid. My own attention was directed to it from the employment of it on a large scale by paper-makers and others to secure the preparation of pure gelatine, a substance peculiarly liable to enter into putrefaction. Sulphurous acid can be easily prepared by burning sulphur, or by heating oil of vitriol, along with charcoal or vegetable matter. Its corrosive action is very slight; its disinfecting action very powerful. The sulphite of soda is now prepared in quantity at different chemical works. The addition of a stronger acid sets free the sulphurous from its salts. As to its mode of action, if we concur with Liebig in believing that morbid matters resemble ferments in being active, only whilst undergoing a decomposition which is mainly determined by the oxygen of the air, we may suppose sulphurous acid to render the poisonous matter inert, by preventing its oxidation. This acid, moreover, is a powerful deoxidizing agent, and it may be by removing oxygen from organic poisons, that it renders them inert, by decomposing them.

Further, sulphurous acid can combine with certain elements of organic bodies, as we see in its temporary bleaching action on vegetable colours; and it may be thus that it neutralizes morbid matters. In one or other or all of those modes, this agent may act as a disinfectant; but at all events its action is very powerful, and it deserves much more attention than it has received.

The only other substance to which I shall at present refer, is pitch oil, one of the products of the distillation of tar. It is an antiseptic of the most powerful class, and very cheap, and if not used in excess it is applicable as a deodorizer, but its own strong tarry smell interferes with its extensive use.—*Pharm. Jour.*

#### ON THE INFLUENCE OF POSTURE IN THE TREATMENT OF EPILEPSY.

By MARSHALL HALL, M.D., F.R.S.

WE have only to raise one hand and arm high above the head, and allow the other to hang down, for a minute or two, and then bring the hands together and compare the syncopeal condition of the former with the apoplectic condition of the latter, to form an idea of the influence of posture in the treatment of diseases consisting of affections of the circulation, especially that of the head.

I believe ordinary syncope may pass into fatal sinking if the raised posture be continued.

I believe that simple apoplexy may become deeper and deeper, simply from the opposite course of retaining the patient in the recumbent position.

Sleep, which is a sub-apoplexy, may pass into epilepsy or apoplexy, solely from the fact of a recumbent position. As a preventive of epilepsy and apoplexy during sleep, it is of the utmost moment that the patient should habitually repose with the head and shoulders much raised. For this purpose both bed and mattress should be raised by means of a bed-chair, or triangular cushion, and the patient be prevented from gliding down in the bed by means of a firm bolster, four inches in diameter, placed under the sheet, under the front of the ischia. The trunk should be raised to an angle of 45 deg. or 50 deg.

In this manner the encephalon will be less oppressed with

blood, the sleep will be lighter, the disposition to epilepsy or apoplexy will be diminished.

This should be the patient's habit during the rest of life.

There are two other circumstances in which attention to posture is most important.

The first is the condition of the patient after certain fits of epilepsy, the respiration being impeded by rattles in the throat. The posture should be much raised; but besides this it should not be such that the saliva may fall into the fauces. The stupor and insensibility prevent the patient from swallowing. The saliva, therefore, if a just position be not adopted, accumulates and falls into the fauces, and a throat-rattle and dyspnoea, painful to witness, and dangerous to life, are the consequence. The posture of the patient should be such as to allow the saliva to flow out of the corner of the mouth. In one case such a change of posture relieved the patient immediately.

The second case requiring extreme attention to the posture of the patient is that of *Syncope Epilepsy*, or that form of epilepsy in which there is ghastly pallor of the countenance and other signs of syncopeal affection. The patient should be placed with the head low. If this be not done, the syncope may be speedily fatal, an event which actually occurred in an interesting case a few days only ago.

The patient was no other than Ann Ross, on whom Mr. Anderson had performed the operation of tracheotomy. Her fits had changed from those of the epilepsy *laryngea* to the abortive form. The reader may remember that the patient's age was thirty-six; that her case was hereditary, her father having been epileptic; and inveterate, her fits having recurred during twenty-four years; and that she herself was thin and pallid. She was seized with syncopeal epilepsy; was laid on the bed and expected to recover as formerly; was left; and was at length found to have expired! A low position and proper attention might have saved the poor creature's life.

I need scarcely observe, that what I have said of epilepsy applies to many other diseases. It is the principle of position which I wish to enforce; a principle the importance of which I believe to be still greater and still more extensive in application than is generally imagined.—*Lancet*.

#### REVIEWS AND NOTICES OF BOOKS.

AN ESSAY ON THE ACTION OF MEDICINES IN THE SYSTEM; being the Prize Essay to which the Medical Society of London awarded the Fothergillian Gold Medal. By F. W. HEADLAND, B.A., M.B.C.S., &c. London. 1852. 8vo. pp. 346.

ON no question, perhaps, have scientific men differed more (the author remarks) than on the theory of the action of medicines. Either facts, essentially opposed and incompatible, have been adduced by the disagreeing parties; or, which is nearly as common, the same fact has received two distinct and opposite interpretations. "Many hypotheses, when tested, are seen (he adds) to be grounded on bare assertions, and to be destitute of logical proof; many others are attempted to be established on ill-sustained analogies." "Analogy, in such a case as this, may be used to increase probability already evidenced; but by itself it is no proof, for we often find that medicines are capable of producing the same result in very dissimilar ways."

The author's mode of treating his subject is somewhat novel. He first lays down a series of propositions (ten in number) respecting the action of medicines, and he then adduces proofs of the correctness of each. The great use of such an arrangement is, he considers, its distinctness; so that it may in any case be easily seen whether a proposition has been established or not.

Mr. Headland's first proposition is—"That the great majority of medicines must obtain entry into the blood, or internal fluids of the body, before their action can be manifested." Of this there are four proofs; thus, "1st. When introduced at another part of the body, a medicine acts in the same way as when placed in the stomach. 2ndly. It is found by direct experiment that a poison will not act through the medium of nerves only, but that its passage in the blood is required. 3rdly. The course of the circulation is quick enough for the most rapid poison or me-

dicine to pass quite round the body from the veins of the stomach before it begins to operate." "The last and most conclusive argument to show that medicines pass out of the stomach into the system, is that they have actually been detected by chemists, not only in the blood, but in the secretions formed from the blood."

In the second proposition it is laid down "that the great majority of medicines are capable of solution in the gastric or intestinal secretions, and pass without material change by a process of absorption through the coats of the stomach and intestines, to enter the capillaries of the portal system of veins." "In the stomach there is (the author observes), in contact with the substance just introduced, a thin watery secretion containing acid and a matter called pepsin; this is the gastric juice. A large number of medicines are soluble in water; they are dissolved in this fluid. Some others are soluble in dilute acid; these too are dissolved here. Albumen, and matters like it, are reduced to solution by the aid of the pepsin, which is the principle of digestion. But there are some few mineral bodies, and many vegetable substances, as fats and resins, which cannot be thus dissolved by the juice of the stomach; they are soluble, more or less, in a weak alkaline fluid; and such a fluid is the bile, which is poured out into the first portion of the intestine."

The third proposition is "that those medicines which are completely insoluble in water and in the gastric and intestinal juices, cannot gain entrance into the circulation."

"Proposition 4. That some few remedial agents act locally on the mucous surface, either before absorption or without being absorbed at all. That they are chiefly as follows:—

Irritant emetics;  
Stomach anæsthetics;  
Irritant cathartics.

Proposition 5. That the medicine when in the blood must permeate the mass of the circulation so far as may be required to reach the parts on which it tends to act.

That there are two possible exceptions to this rule:—

The production of sensation or pain at a distant point;

The production of muscular contraction at a distant point.

Proposition 6. That while in the blood the medicine may undergo changes, which in some cases may, in others may not, affect its influence. That these changes may be of combination, as of an acid with an alkali; of reconstruction, when the elements of a body are arranged in a different way without a material change in its medical properties, as when benzoic is changed into hippuric acid; or of decomposition, when a substance is altogether altered or destroyed, as when the vegetable acids are oxidized into carbonic acid."

Having considered these preliminary points, we shall arrive (the author remarks) at the main point—viz., how medicines operate in the cure of disease. This is followed by a classification of medicines according to their supposed mode of operation. The author is of opinion that medicines which act after entering the blood, may be divided into four groups or classes, the action of each of which is well marked and distinct.

"The first class acts on the blood, and as a large number of diseases depend on a fault in that fluid, we may by their means be enabled to remedy that fault. They are the most important of all medicines; they are called *hæmatics*, or blood medicines. They are used chiefly in chronic and constitutional disorders. A second class of remedies are temporary in their action. They influence the nervous system, exciting it, depressing it, or otherwise altering its tone. They are chiefly useful in the temporary emergencies of acute disorders. They can seldom effect a permanent cure, unless when the contingency in which they are administered is also of a temporary nature. They are called *neurotics*, or nerve medicines. A third set of medicines, less extensive and less important than the others, acts upon muscular fibre, which is caused by them to contract. Involuntary muscular fibre exists in the coats of small bloodvessels, and in the ducts of glands. Thus, *astringents*, as these agents are called, are able, by contracting muscular fibre, and thus diminishing the calibre of these canals, to arrest hæmorrhage in one case (when a small vessel is ruptured), and to prevent the out-

pouring of a secretion in another case. The fourth class is of considerable importance. Some medicines have the power of increasing the secretions which are formed from the blood by various glands at different parts of the body. By their aid we may be enabled to eliminate from the blood a morbid material through the glands; or we may do great good by restoring a secretion when unnaturally suppressed; they are called *hæmatics*. Like *hæmatics*, their influence is more or less permanent. That of *neurotics* and *astringents*, particularly the former, is transient."

The following is the classification of medicines given by the author, founded upon his views of their mode of operation:

**Class 1. HÆMATICA.**

**Div. 1. Restaurantia.**

- Ordo 1. Alimentaria.
- 2. Acida.
- 3. Alkalia.
- 4. Tonica.
- 5. Chalybeata.
- 6. Solventia.

**Div. 2. Catalytica.**

- Ordo 1. Antiphlogistica.
- 2. Antisyphilitica.
- 3. Antiscrofulosa.
- 4. Antiarthritica.
- 5. Antiscorbutica.
- 6. Antiperiodica.
- 7. Anticonvulsiva.
- 8. Antisquamosa.

**Class 2. NEUROTICA.**

**Div. 1. Stimulantia.**

- Ordo 1. Stimulantia generalia.
- 2. Stimulantia specifica.

**Div. 2. Narcotica.**

- Ordo 1. Inebriantia.
- 2. Somnifera.
- 3. Deliriantia.

**Div. 3. Sedantia.**

- Ordo 1. Sedantia generalia.
- 2. Sedantia specifica.

**Class 3. ASTRINGENTIA.**

- Ordo 1. Astringentia mineralia.
- 2. Astringentia vegetabilia.

**Class 4. ELIMINANTIA.**

- Ordo 1. Sialagoga.
- 2. Expectorantia.
- 3. Cathartica.
- 4. Cholagoga.
- 5. Diaphoretica.
- 6. Diuretica.

The general mode of action of these four classes of therapeutic agents is laid down in the following propositions:—

"*Proposition 7.* That a first class of medicines called *hæmatics*, act while in the blood, which they influence. That their action is permanent:—

- 1. That of these, some, called *restoratives*, act by supplying, or causing to be supplied, a material wanting; and may remain in the blood.
- 2. That others, called *catalytics*, act so as to counteract a morbid material or process; and must pass out of the body.

*Proposition 8.* That a second class of medicines called *neurotics*, act by passing from the blood to the nerves or nerve-centres, which they influence. That they are transitory in action:—

- 1. That of these, some, called *stimulants*, act so as to exalt nervous force in general or in particular.
- 2. That others called *narcotics*, act so as first to exalt nervous force and then to depress it; and have also a special influence on the intellectual part of the brain.
- 3. That others, again, called *sedatives*, act so as to depress nervous force in general or in particular.

*Proposition 9.* That a third class of medicines called *astringents*, act by passing from the blood to muscular fibre, which they excite to contraction.

*Proposition 10.* That a fourth class of medicines called *eliminatives*, act by passing out of the blood through the glands, which they excite to the performance of their functions."

In the last chapter, the author considers, separately, some of the more important medicines, in order "to enable him

to illustrate some general principles of their action, and to show in what measure, they are applicable to special cases." The principal of these, which our limits permit us only to name, are cod-liver oil, quinine, iron, antimony, mercury, iodine, arsenic, chloroform, and digitalis. We cannot, however, conclude this short notice of Mr. Headland's work without adding that he has treated a very difficult subject in a novel and highly scientific manner; and no one we think is likely to question the soundness of the judgment or the correctness of the decision of the judges by whom the Fothergillian medal was awarded to him for this essay.

**MEDICAL PRESS.**

SALUS POPULI SUPREMA LEX.

DUBLIN: WEDNESDAY, JANUARY 5, 1853.

**MEDICAL REFORM.**

THE return of Sir JAMES GRAHAM to office reminds us of Sir JAMES GRAHAM'S Bill and "Medical Reform" for some time consigned to the historical records which chronicle *de rebus perditis*. It is now some seven or eight years since this Cabinet Minister and then Home Secretary, entertained this matter so seriously that, at his instigation, the Colleges of Surgeons of England and Ireland obtained new Charters to enable them to adapt their arrangements to the proposed new medical organization; and surely it is now high time to have it definitively settled whether or not we are to be left to the tender mercies of the Universities and Medical Corporations for relief in this matter. If, in 1844, a necessity existed for the changes so often suggested in schemes of Medical Reform, we can, without fear of contradiction, assert that the same necessity now exists in a ten-fold degree. The charters then granted, not having been rendered operative by the proposed and promised act of parliament, have proved not only powerless for the correction of abuses and the promotion of improvements, but absolutely have led to consequences which never could have followed under previous regulations; so much so, that the English College of Surgeons has been obliged to obtain another Charter, and that of Ireland is now engaged in making arrangements with a similar view. This result is not very flattering to our profession, indicating as it does some radical incapacity for self-government; but after all, where is the department that has been left to self-government without equally lamentable consequences? The three offsprings of academic nurture, Law, Physic, and Divinity, have proved by their acts that it is the same with all; and that nothing but the strong arm of inexorable law, set in motion by an overwhelming expression of public opinion, can restrain men from sacrificing public to private interests. We would not intimate that we entertain any great partiality for the scheme embodied in the Bill to which we allude; what we wish to express is, an opinion that the steps taken in 1844, at the suggestion of the Home Secretary, should either be retraced or followed up by legislation in the same direction. There is no use in concealing it, an executive government, directly or indirectly chosen by a narrow majority of even a large body of electors, must often have its efforts to correct abuses rendered ineffectual by the intrigues and clamours of a very small minority; and therefore is it that without an act of parliament to enforce obedience to rules, supported by charters and bye-laws only, no salutary control can be exercised. Abuses and malpractices become established either by neglect or collusion, until those profiting

by them acquire a kind of vested right to their fruits; and then be the evil consequences ever so great, they cannot be averted, so powerful is the resistance which a common interest enables a very small body of men to offer. Thus it is that discipline has become relaxed in schools, ostensibly under collegiate control but practically repudiating it; prescribed exercises are evaded; and even attendance itself is dispensed with, until the whole affair degenerates into a disreputable trade in certificates and an artificial preparation for examination. The mischief, however, does not rest here, for the seeds of corruption once sown spread in every direction; and thus combinations the most unexpected arise, and interests are identified in a way which no sagacity could have anticipated. A new state of affairs has arisen, and to this state the laws of a different one are inapplicable. Our profession was once under the salutary control of certain unwritten laws, whatever new-comers may say to the contrary. The law of opinion in fact exercised a powerful influence upon it; but be the cause what it may, that influence no longer operates to the same extent, and hence the necessity for something more stringent. We confess for ourselves that our sympathies are not with the new school of medical morality, which openly proclaims its belief in the worthlessness of character, and relies exclusively on more solid acquisitions. We, however, ask pardon of the gentlemen who seek nothing for their labours but money, and to obtain it hesitate not to support any policy which promises to promote that object. If they be not "too fond of the right to adopt the expedient," that is no business of ours as regards personal character; but as regards the characters of institutions and our profession at large, it is our duty to interpose.

### MEDICAL LIFE IN LONDON.

London, December 25, 1852.

At the close of the year, we would wish as much as any one to make the crooked ways of the profession straight, and rough places plain. We feel, however, some sort of "lustration" or purifying process is wanted, after having of late to touch such disagreeable if not disgusting topics. Would to heaven the abuses of the profession were not open, palpable at every turn, and that we might wind up with a few Christmassy words and plum-pudding. It is little use, however, to sacrifice truth for mere holiday effect: if you expel truth by force, as Homer and Colonel Sibthorp say, it will still ever return. Shams and nonsense may have their day, but "joy cometh in the morning." This morning, we believe, as far as London and its colleges and practitioners are concerned, is still a far way off.

We are all at present very busy discussing the evidence of the late supposed murder near Dublin. Notwithstanding yellow fever is at Southampton and quackery and bad practice in every street of London, we have a great deal of superabundant wisdom for people far off. Though individually of opinion that the man lately found guilty of murder in Dublin, was found guilty on insufficient testimony, we would rather be spared the work of supererogation of the *Lancet*. We should prefer a question of such moral and medical nicety not ranking as a matter of sale with the adulterations of anchovies. Medical men cannot be too guarded in their evidence. Robert Adams, it is felt, would be more at home in

some abnormality of the elbow-joint; but considering the case in all its bearings—the uncertain nature of the congestion caused by drowning, the difficulty of specifying, or even imagining, what other thing helped the death—the negative character of the medical evidence is more to be recommended than the opposite. If the jury were not fit to try the case, the medical witnesses should not be visited with the opprobrium of their incapacity.

A plum-pudding we intend at present as more germane to the season, unless the old figure of a pudding without a bag is best represented by the profession in London. We say little of the physicians, a body nearly unknown in practice, so completely have cheap diplomas and examining boards deluged the wide table-land of practice of medicine with quackery. A plum-pudding of the true Christmassy sort did we say? Sybaris in the arms of Lydia not more enchanting! With Horace, too, we might sing, stir up the fire, and bring out some of the four year's old wine from the Sabine jar; but we have not thought us of a pudding-bag; there is no cohesiveness or consistency; the materials perhaps excellent in their way—the mere elements of medicine and surgery in London the most beautiful the world ever saw—the citron, flour, eggs, and currants, so to speak, unexceptionable, and all the other materials as good in their way, but no skilled hand to put the jarring elements together. Churchill and Highley, the citron and lemon, in vain mixed up with the badly-made dough of clinical lectures and new books, which form the staple of medical reading and study; the *Lancet*, the basin to hold everything in which *Punch* might represent the "bubble bubble" of the pudding being mixed: everything professional broken to pieces with the other materials. Dr. Paris, of course, and the College of Physicians, the chips (in porridge), should we say, of cinnamon? Brown and flavoury some; the *Pharmacopœia* and poor Collier a grating of nutmeg, the most spicy thing in the profession since Abernethy and Sir Astley went out. The remaining essentials painfully remind us of a Chancellor of the Exchequer's budget—tea, bricks, house-taxes, and beer, that no magic in the web of our discourse can make to coalesce. Your unsteady old friend, the *Medical Times*, the fluid for the dough, keeping, like the *Lancet*, everything in hot water, and making even more ingeniously a mess of hospital lectures, essays, and leading articles. Alas! could the world but see, like the young salamanders in water, according to Hassall, the slime and abominations in the limpid springs of our journalism, the jealousies and meanness in Reviews, the cruelties practised by the *Legrees* of the press, they would abjure them for ever.

The editors of the hebdomadaries we willingly spare, whatever ingenuity they show in whipping the eggs of our pudding and mixing the batter: the eggs, the batch of medical contributors. Some, it may be, a little time on the shelf, and mouldy; others, really valuable; and many neglected, but characterized by that kind, gentlemanly feeling that should give consistence to the profession, and adorn it. Our Hunters and Jenners in the present pleasant age of unrestricted competition, our young men, who till they wear wigs and can pay the booksellers, have not the most ghostly chance of getting on in London.

We are forgetting the currants and raisins; though one is at a loss to find anything so good and pleasant in the dreary abysses of English medical literature as fruits coming from abroad. Rokitansky, Mulder, Oken, Kölliker, Biot, Scarpa, and other dried fruits sprinkled through Paget, Owen, Golding Bird, &c., well represent this part of our confection: the stones out of the raisins, of course we would get rid of, \* \* \* \* of whom and of which we know very little, and would wish to know less. We are very much inclined to agree, too, with our Edinburgh friends, that all that style of literature advances the profession very little.

The reader might wish to change the metaphor, being as

tired of it as ourselves, but we might be doing some silent good by going on to the end. According to various others, then, Sir Benjamin Brodie, Mr. Guthrie, Mr. Stanley, Dr. Marshall Hall, Mr. Skey, Mr. Simon, and others, are the hard grains it is advisable to pick out of our fruit before a plum-pudding is practicable. Curious, crotchety men we believe some of them to be, but crotchety generally in the right. Who, however, does not remember Lady Macduff? She, too, has done no harm; but placed in an imaginary

an earthly world, where to do harm  
Is often laudable; to do good, some time  
Accounted dangerous folly.

So with many of our friends aforesaid. Sir Benjamin Brodie, for instance, is the most learned man in the profession in London, but the man who has most enemies; Mr. Lawrence, perhaps, the most friends, without any boasted learning. Mr. Guthrie has done more for military surgery than any man who ever lived, and should now be at the head of the medical department of the army; but like Roly O'More's dreams, all our medical appointments here "go by contraries." The square pegs are ever getting into the round holes, and the round pegs into the square holes. Dr. Marshall Hall has been laughed at and ridiculed till it no longer "pays;" but his name is now known through the world, and his reputation, if he will only guard it safely, quite equal to Sir Charles Bell's. Men of a certain class deny any force to the excitomotor system of nerves, as Marshall Hall has not given a map and an anatomical description of them. The spinal cord is, no doubt, the centre of these actions. These men wilfully overlook the fact, but were poor Hall to have written from the swamps of the Lower Rhine, or from Vienna, and have a name no one could pronounce, the booksellers' shelves would groan with his discoveries. Mr. Skey is another of the hard grains of our Christmas' fruit; few men of the present day, however, can boast of such a strong masculine intellect. Sitting at the feet of his Gamaliel, whom he half worships (Sir Benjamin Brodie), the combined wisdom of these two great men is something indeed to think of. Mr. Skey laughs at all authorities of the olden time. Mr. South, on the other hand, with his placid mein and hair parted like a woman's, would frame and glaze the washing bills of the ancient surgeons; would revive *queues*, perpetual pills, red-hot amputating knives, and Ambrose Paré.

Some other of the men here (the discordant elements of London medical practice) are perhaps not less singular in their characteristics. As we may not have another opportunity of serving up our currants and raisins again, we may speak of them. A dash of sugar is required, but then there is Mr. Lawrence; a little suet shredded fine, Dr. Ramsbottom; Alfred Smeé, and a few fat general practitioners, cut up small; a piece of mistletoe is wanted of course, to stick a-top of our pudding, under the beamy smiles of which we may all love and greet each other, Professor Owen; some thorns to put under the pot, when we have procured a pudding-bag—thorns crackling as the manner of fools according to high authority, the homœopaths. With a little unanimity and honesty, this desirable consummation might be achieved. A little spirit to burn under the dumpling from the bitter beer testimonials and some of our useless museum preparations. We would wish a place for our prescribing chemists, but it would be very near the thorns under the pot. Then there are others which in time will also prove useful, one way or another. Mr. Coulson, if he would only not aspirate his vowels, invulnerable on the subject of lithotomy and lithotripsy; Bence Jones at St. George's, who would turn everybody's brain he talks to into sulphurets and phosphates; Dr. Robert Lee from the wintry side of the Tweed, old fashioned, but marvellous in industry, with one arch enemy, Dr. Snow Beck,

and one abiding fancy, uterine diseases; Loebeck, stern and unbending in practice; Bennett, fanciful, ever dreaming of the speculum; Golding Bird, insinuating, sharp, and puritanical, goes to church only five times on Sunday, but not to be approached as a good physician, especially in children's diseases; Fergusson, need we say, the *beau idéal* of a surgeon, simple, kind, and gentlemanlike, without humbug; Bransby Cooper the same; Babington, Addison, and Watson, the great pillars of medicine in England, without whom it would all tumble to the ground; Copland, not much known, but indefatigable, like the "busy bee," improving "each shining hour," &c.; at Bartholomew's, Lloyd, one of the "illustrious unknown," preferred by his friends to poor Sam Cooper as surgeon to that institution; Paget, the rival for Skey's place; and Skey adored and envied by every one; these all, no doubt, will be found in time among our "representative men"—when some connecting influence is discovered to bring together all the good men in London now sadly distracted—when nepotism, practising chemists, and genteel starvation are at an end; when the College of Surgeons, like the *lethysaurus* or *Dinornis* is reconstructed and remodelled—when the College of Physicians is no longer like a set of genteel catacombs, but common sense and proper professional thinking the rule of life most tolerated and valued.

Our fancies here are ended. Our Christmas fare may not be very digestible, as all orthodox plum-puddings are expected to be; but if we could instil into the minds of Irish readers the value of their simpler and less sophisticated science, the vast superiority of medicine as a profession in Ireland, our efforts may not have been in vain. For cheapness of living, agreeable society, and a thorough grounding in the various subjects that engage a student's four years, we unhesitatingly recommend Paris or Dublin; for utter sickness of soul, humbug, and insufficient teachers in various departments, we shall back London against the world. As a field for practice, we would say to every honest man leave your honesty at home. You will meet thousands of friends out of the profession: not one in it. Envy, bickerings, malice, and all uncharitableness, the well-recognized normal arrangement of everything and everybody. The Hunters and Harveys of to-day starving as of yore; the star of quackery, bad journalism, and colleges, the only one in the ascendant.

## CONSULTATION WITH QUACKS.

THE following, although not very intelligible, raises the question of "consultation with quacks," and with it the other question, "what is a quack?" Our belief is, that there is much more business doing in this way than people think. The correspondent of the *Lancet* says the Whitehaven Practitioners cannot be charged with mean practices; but, then, another says they "visit cases in conjunction with quacks":—

An unjustifiable attack has been made in last Saturday's *Lancet*, by an anonymous "Subscriber," on the medical practitioners of this town, in stating that some surgeons are "in the habit of visiting cases in conjunction with quacks and unqualified practitioners in the neighbourhood." I am proud to say that the medical men in Whitehaven are as particular in observing the honourable practice of their profession as those of any other town in the kingdom, and I am quite certain there is not one who can be charged with "mean" practices. Through the inefficient working of the Apothecaries' Act, there are several persons practising in the neighbourhood who are not "Licentiates of the Hall." The two nearest towns, Harrington and Egremont, have not a licentiate of the Apothecaries' Company residing in them. The poor-law appointment in the former place is held by a person who has no legal qualification, and in the latter (Egremont) by the possessor of a single qualification. These remarks will, I hope, be sufficient to remove the imputations of your correspondent,

whom I expect will not make such general charges on my professional brethren without sufficient reasons.

How is this in Dublin? Quackery, we know, within the pale, is not only no disqualification for consultation, but a positive qualification; without the pale, as when a man openly avows his disregard of all professional obligation, it may be otherwise. Is it true that the most barefaced and impudent advertising does not disqualify for consultation? Is it true that to openly repudiate all obedience to the unwritten laws which govern the conduct of professional men is held to be a venial offence?

#### CORRESPONDENCE.

##### TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—In your paper of the 8th of December, you give a code of "Pharmaceutical Ethics," framed by the Medical Society and College of Pharmacy of Philadelphia, U.S., and you commend its candid and patient consideration to the Dublin practitioners in this line. Now, sir, my object in writing to you is to show the Philadelphia faculty, who, as a matter of course, read the MEDICAL PRESS, that your recommendation of their code of laws will never be attended to as long as the present system of gross neglect, with regard to professional acquirement and legitimacy, exists within the States; because there is no man could respect the laws of a body, who allow Tom, Jack, and Jerry to practise physic and pharmacy in their country; never taking the trouble of inquiring whether he is a tinker or a tailor, but permitting him to practise, to the loss and detriment both of the legitimate practitioner and the public. This is too well known a fact to admit of even the least denial. I am myself cognizant of such a case at present in the city of St. Louis, Missouri, where a man, who was brought up to honest business in this good city of Dublin, went to St. Louis, and having the audacity to write Doctor before his name, is now nearly twelve months in practice as an apothecary and doctor, though he never lost one hour in the attainment of medical or pharmaceutical knowledge, and here is this impostor making his fortune; while men who have wasted years of toil and some hundreds of pounds before they could obtain a degree, are not able to get a crust in the same city. Now, sir, if a proper law was instituted by the legislature, I ask you would this be the case? If the colleges of Philadelphia had a branch committee in every city and town in the States, whose duty should be to go around annually and demand the diploma of every person calling himself a doctor, surgeon, or apothecary, and practising as such—if such an arrangement was, I ask you would this state of things continue? By taking the names and dates of the several diplomas exhibited, they could communicate with the colleges at home, and soon discover whether the holder of each diploma was its original possessor: thus would the chaff be separated from the wheat, and while the legal practitioner would be thus protected, the culprit, when exposed, would be greatly benefited by a three months' dance upon the treadmill, or twelve months solitary confinement; with a caution that if caught so offending again, the full rigor of the law would be brought to bear upon him.

To each sub-committee, some little trouble in the carrying out of the foregoing arrangement may be given for the first year, but there it would cease, for every year after it would be only the diploma of those who had commenced practice since the previous examination that they would have to inspect, and by men who love their profession as a noble and an honourable one, this task would be cheerfully performed; and believe me all quacks and impostors, glorying in stolen or borrowed imaginary plume, would very soon sink into their former insignificance.

When the Philadelphia colleges act thus for the safety and honour of their profession, then will their brethren at this

side of the Atlantic read with pleasure every paper and advice emanating from them, and America will bless the day that they came forward to save her children from being butchered and poisoned by these despicable wretches—these self-made M.D.'s and apothecaries of her Western States.—I am, sir, yours, A SUFFERER BY QUACKERY.

##### TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—As I understand there is to be a meeting of the Medical Officers of Dispensaries held in Dublin next month, I respectfully suggest that the medical officers of each union should meet and appoint one of their body to represent them at the general meeting. They should also, in my opinion, subscribe in order to defray the expenses of their representative, as it would be unreasonable to expect that those living at a distance from Dublin should pay their own expenses.—I have the honour to be, sir, your obedient servant,

JAMES P. SHEEHAN, M.D.

Buttevant, December 30, 1852.

##### TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—How is India-rubber made into thin sheets? How can its cut edges be firmly united? What is the best solvent for it? Can it be made into a soft plastic state and moulded? If so, how? Your reply in the next number of the PRESS will oblige

A SUBSCRIBER.

##### TO CORRESPONDENTS.

THE number and variety of claims on our editorial offices at this particular period of the year, places us somewhat in arrear with correspondents, but their communications are not forgotten. The doings in the Athlone Union must be noticed, and the more difficult matter further south well considered. To the case of the convict Kirwan we propose to return presently, when the letters of correspondents will be made available. The article to supersede the previous one arrived too late; we, however, pruned some thorny shoots, and the plant will do very well.

LUXATION OF ACROMIAL END OF CLAVICLE.—M. Velpeau has seen now fifty cases of this luxation, and is satisfied that it is, as it were, natural to some persons. If these individuals should fall, they erroneously suppose that the luxation was caused by the fall. It is possible that this luxation is natural on one side, and not on the other. In all these cases, it is of no importance, so that when left to itself, it does not prevent the use of the arm, which it is necessary to be aware of, when it is recollected how difficult and even impossible it is to keep it reduced. In such cases, M. Velpeau does not needlessly inconvenience the patient, he merely applies the apparatus for fractures of the clavicle. This he removes the fifteenth day, and in a month after that the movements of the arm are restored.—*Presse Médicale de Belge.*

**DR. BELLINGHAM ON ANEURISM.**

Lately published, 12mo, price 4s.  
**OBSERVATIONS ON ANEURISM AND ITS TREATMENT BY COMPRESSION.**

By O'B. BELLINGHAM, F.R.C.S.I.,  
One of the Surgeons of St. Vincent's Hospital.

"In our opinion, he has conferred a signal benefit upon the art of surgery by his improvement of the mode of employing pressure, and upon the science by his ingenious and philosophic exposition of its operation."—*Medico-Chirurgical Review*.

"Dr. Bellingham has ably advocated the cause of compression as a highly useful and successful mode of treating numerous cases of external aneurism."—*Lancet*.

"Dr. Bellingham's little work is well worthy of attentive perusal, and we feel a confident hope that henceforth another formidable operation (as ligature of the femoral vessel even under favourable circumstances unquestionably is) may in a great majority of instances be avoided."—*American Journal of the Medical Sciences*.

"The very excellent and practical essay lately published by Dr. Bellingham, to which we would refer our readers, as containing a most masterly account of the treatment of aneurism by compression."—*British and Foreign Medical Review*.

"I conceive that for a just exposition of the principles on which that mode of treatment should be conducted, as well as for some valuable improvements in the mode of procedure itself, the surgical profession is mainly indebted to you."—*Sir Philip Crampton's Letter to the Author*.

**TO THE MEDICAL PROFESSION AND THE PUBLIC.**

GEORGE OLDHAM AND CO.,

**APOTHECARIES AND CHEMISTS,**

in availing themselves of the present opportunity to return their grateful acknowledgments to their Friends for the support which they have hitherto received, and which they will regard as a fresh motive for exertion, beg leave to announce that they have taken the

**ROYAL MEDICAL HALL, 64, DAME-STREET,**  
(Late Bewley, Owen, and Co.'s.)

which they will henceforward conduct in connexion with their

**MEDICAL HALL, 107, GRAFTON-STREET.**

In notifying the above change in the management of the Royal Medical Hall, G. O. and Co. can assure the present friends of that establishment, that the same scrupulous attention and care has been paid to the selection and preparation of their Medicines and other articles, which has gained them such extensive support in their Medical Hall, 107, Grafton-street; and they hope their arrangements to ensure accuracy, neatness, and despatch, combined with moderation of charges, will merit the approbation of those who may entrust them with their commands.

☞ The Royal Shaving Cream, Essence of Ginger, Matico, Tooth Powder, Essence of Rhubarb, Ginger, and Chamomile; and other preparations heretofore made and sold at the Royal Medical Hall, can now be had at either Establishment.

107, GRAFTON-STREET,

AND

64, DAME-STREET, DUBLIN.

**TO SURGEONS, DISPENSING CHEMISTS, ETC.**

**SULPHATE OF QUININE**, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, capsuled, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.

**RENVYLE DISPENSARY DISTRICT,**  
**COUNTY GALWAY.**

WANTED a RESIDENT MEDICAL OFFICER at a salary of £75 a year. The Election will take place on TUESDAY, the 11th of January, 1853, at Twelve o'clock. Candidates must attend in person on the day of election, and produce qualifications according to the regulations of the Poor-law Commissioners.

Qualifications and testimonials to be forwarded to the Chairman of the Committee, James Ellis, Esq., Letterfrack.

# NEW FEATURE

## IN

# THE BRITISH AND FOREIGN MEDICO-CHIRURGICAL REVIEW.

COMMENCING WITH THE JANUARY NUMBER.

(PUBLISHED QUARTERLY, PRICE SIX SHILLINGS.)

### NOTICE BY THE EDITOR.

Some changes have been introduced into the current Number of the Review, which demand a few words of explanation.

The names of the reviewers are, in several instances, affixed to the reviews. It is hoped, by this plan, to make the criticisms even more valuable than formerly—since the reviewer will appeal more authoritatively to his own experience. A review is simply an inquiry into the validity of an author's statement by the aid of previously-admitted facts, or by the assistance of others known only to the reviewer as the result of his proper observations. To give these last their due weight, they must be authenticated. A writer who merely builds up his argument with well-known truths, or with the opinions of other men, may remain anonymous, but whenever he resorts to his own experience, he must guarantee it with his name. An unavowed statement is dead to science, and no one recognizes a veiled authority.

By far the most valuable kind of criticism is that in which a reviewer starts from the same point as his author, and treading in his footsteps, explores afresh the same country, confirms what is true, and corrects what is inaccurate. We have seen this mode of reviewing carried in this country to as high a degree of perfection as the employment of the incognito can ever permit. It remains to be seen whether it may not be made still more authoritative, and therefore more valuable; whether, in fact, it may not be possible to permit no statement to pass into the currency of general belief until a second name has been affixed to it, as a guarantee that the evidence on which it is made has been tried, and not found wanting.

By the adoption of this plan, also, it will be possible to bring more frequently before the profession the matured views of experienced men in various departments of medicine. At present, such reviews lose much of their weight, because their authors are unknown, and they are less numerous than they might be, since no one wishes to put the labour of years into an article which carries with it no evidence of its source.

It is not intended, however, to lay aside altogether the incognito. In some cases the addition of the name may, perhaps, be unnecessary; in others, inexpedient. Experience alone can show how far the interests of truth and science may demand publicity, or warrant secrecy.

In order to maintain the high character of the reviews, the aid of the most competent men will be sought; and no assistance that is worthy and honest will be disdained. This journal has never been, and will never be, the organ of a section or a party; it is a catholic work, in which all who love their science will be invited to join.

Some Original Communications are now, for the first time, introduced. A new and advantageous medium of publication is thus afforded, and the journal itself will gain in variety, interest, and utility. Occasionally, it is intended, also, to translate foreign papers of peculiar merit, of which an example appears in the present number.

The terms "Chronicle" has been substituted for that of "Periscope," as expressing more fully the intention of this part of the Review, which is to record as concisely, though as faithfully, as possible, the progress of Medical Science.

### CONTENTS OF No. XXI.

#### ANALYTICAL AND CRITICAL REVIEWS.

1. Wunderlich and Wood on the Practice of Medicine.
2. Kölliker on Blood-corpuscle-holding Cells.
3. Crises and Critical Days.
4. What is Bright's Disease?
5. Miller and Ferguson on Surgery.
6. Lehmann on Physiological Chemistry.
7. Lebert on Cancer.
8. Sugar in Urine, and its Tests.
9. Néligan on Diseases of the Skin.
10. The Diseases of Children.
11. Cole on Field Service in India.
12. Memoirs of the French Academy.
13. Fuller on Rheumatism.
14. The Predisposing Causes of Epidemics.
15. Hannover on Epithelioma.
16. Tubercle and Pthisis.

#### BIBLIOGRAPHICAL RECORD.

1. Dr. Ballard on the Physical Diagnosis of Diseases of the Abdomen.
2. Proceedings of the Pathological Society.
3. Velpeau on Midwifery.
4. The Quarterly Journal of Microscopical Science.
5. Dr. King on the Fever at Boa Vista.
6. Fownes and Bowman on Chistia.
7. Thomson's Dictionary of Domestic Medicine.

8. Ellis's Demonstrations of Anatomy.
9. Kölliker's Manual of the Anatomy of Tissues.
10. Hubener on Special Pathology and Therapeutics.
11. Dr. Robertson on the Buxton Waters.
12. Dr. Carpenter's Physiology.
13. Dr. Burslem on Consumption.

#### ORIGINAL COMMUNICATIONS.

1. On Iodide of Potassium in Metallic Poisoning. By M. Melsens, translated by William Budd, M.D.
2. On certain Elastic Structures connected with the deep Flexor Tendons of the Fingers and Toes. By John Marshall, F.R.C.S., &c.
3. On the Function of the Muscles of the Tympanum in the Human Ear. By Joseph Toynbee, F.R.S., F.R.C.S.
4. On the Specific Gravity of the Brain. By W. H. O. Sankey, M.D.
5. The Action of Liquor Potassæ on the Urine in Health. By E. A. Parkes, M.D.

### MISCELLANEOUS CASES AND OBSERVATIONS IN THE PRACTICE OF MEDICINE.

By J. KIRBY, LL.D.,  
Ex-Professor of the Practice of Physic in the Royal College of Surgeons, &c. &c.

#### IRRITABLE TUMOUR OF THE BREAST.

Miss —, aged 30, thin and sallow, received a contusion in the right breast, which is very small, six months ago. She has since experienced much pain, for which she had leeches applied at different times, and other applications, advised, and always with relief.

She now complains of occasional pain, heat, and uneasiness in the axilla, shoulder, and arm of the same side. She is greatly afraid of cancer. The breast bears to be handled, and it seems to be in a healthy state; but two of the axillary glands appear to be larger than natural. Her bowels are costive. The menstrual period occurs regularly, but the discharge is deficient in quantity, and she suffers much on that occasion. She is ever looking at and feeling the bosom, by which circumstance her mind is constantly disturbed.

I prescribed some medicine and a mixture composed of inf. gent., comp. decoct., aloet. comp. and camphor, with an anodyne liniment to be rubbed to the shoulder and axilla. In some time she got perfectly well.

#### ON CARTILAGINOUS TUMOUR OF THE BREAST.

I have seen three cases of this disease, and as they were all in females under twenty years and unmarried, I presume it to be incidental to that period of life. They were of slender make, and their bosoms were of an unusually small size, scarcely raised above the surface, without any development of the mammary gland, and the nipple was deficient both in size and prominence.

These tumours were situated to the axillary side of the areola, and somewhat above it. In form they were roundish, about two inches in diameter, with an irregular but well-defined margin. They were of the thickness of the eighth of an inch, flat and quite moveable, both to the

parts beneath and above them. They seemed to be made up of many parts, which, however, did not allow of any reciprocal motion between them. There was neither heat nor discoloration of the skin, nor did handling cause any uneasiness either in them or in the parts beneath them. When raised they would bend like cartilage, but on the removal of pressure, they at once resumed their original form.

The existence of these tumours was accidentally discovered, and of course I could not collect anything of the manner of their growth or the duration of their presence. The axilla was free from any engagement. The bowels were regular, and the catamenia were natural. There was no evidence of any locally strumous affection, though these females had that complexion and those features which are esteemed as characteristic of a truly scrofulous disposition.

As it appeared to me that there was not anything in these tumours to demand any heroic treatment, nothing such was suggested, nor even hinted at. I merely covered them with a plaster composed of London soap plaster, strong mercurial ointment, extract of belladonna spread on mole-skin, and I desired it to be renewed as frequently as they disengaged them. I also advised pills made of pil. Plummeri, pilulæ ferri comp. and pil. aloet. compos., one of which was to be taken at night for some time, with the ext. sarsap. twice daily, and I desired them to use simple diet, to take wine sparingly, to avoid malt, to clothe themselves warmly, to be provided against cold, and to take much exercise on foot out of doors.

In less than three months the tumour had greatly declined, so that there was no necessity to make any change in a plan which so far answered very well.

One of these ladies wrote to me in some time that the disease had completely disappeared, and that she was now married.

The others I have heard of, and there was no perceptible trace of the tumour. Both have since been married, and all three made excellent nurses.

I have been consulted by many females, on account of diseased sensation in one of their breasts, which made

them very uneasy, although they were to all appearance in abundant health. Their bosoms were large, whether they had been mothers or not, and they complained of a morbid sensibility over the entire breast. They could not bear my touch, while they handled it carelessly and roughly themselves.

Comparing it with the other side, each appeared to be somewhat larger and hotter to the hand than the other. All had uneasiness in the shoulder and arm of that side, but the irritability and size of their bosoms prevented me from arriving at any conclusion on the subject of there being any disease or none. I assumed the latter, and I advised aperient pills, to keep the breast suspended with a handkerchief, to avoid all improper pressure and exercise of the limb, and occasionally, when they found the bosom hot, to bathe it in cloths soaked in an evaporating lotion. I also advised exercise.

Now, these females belonged to a class who enjoy all the luxuries of life. They rise late, having usually breakfasted in bed, on all the good things which can be spread before them. They have their toilet made by two o'clock, at which time they partake of luncheon and wine; they then ride out in their carriage for two hours; they then take a "siesta," dress for dinner, and partake, at a late hour, of whatever is then before them, with an eager appetite, and they drink more wine. When dinner was over they made themselves very comfortable with much luxury, laid themselves on their sofa, and fell to sleep until the hour came for retiring, when they had their arrow-root, or their gruel, seasoned with wine, for their supper.

Now, these females are oftentimes under the influence of evangelical feelings, and thinking it to be no sin to use the good things of this life without abusing them, they call for wine on many occasions. If the bowels are uneasy, or their head aches; if they are much excited, or are sunk in deep despondency, so then they may be said to be true and devoted captives to the bottle, which they believe to supply the place of every medicine on the surface or beneath the surface of the globe.

A visit to some aperient spa sometimes does these people much good, especially if the medical practitioner they consult is a rigid imposer of regimen, and a strict disciplinarian in the use of wine or any substitute for it.

In the cases I have seen I have always been able to trace their disease, or their deranged sensation in the bosom, to an overweening indulgence in vinous fluids, believing in its curative virtues. When they found themselves improved from its sparing use, matters amended considerably, and when it was given up altogether every unpleasant feeling disappeared, and every apprehension it so constantly produced vanished for ever.

#### ON THE SCIRRHUS TUBERCLE OF THE BREAST—ACTIVE SYMPTOMS, TREATMENT, AND DEATH.

Miss B——, Mountjoy-square, aged about 30, was engaged in a short and anxious attendance on her mother, who died of apoplexy.

In a week afterwards she called at my house to consult me about a tumour of her left breast, which she did not perceive until two days before the death of Mrs. B., whom she frequently lifted in her bed for one purpose or another. She thought it arose from a strain, and she disregarded it, thinking it would be well in a few days, but now she feels a rather sharp and pricking pain on motion of her arm.

The tumour, which is of a considerable size, is situated to the axillary side of the nipple, which is somewhat engaged, being slightly retracted. It is immovable, and is very hard and rather irregular. It cannot be circumscribed, but is lost in the mammary structure, of which it is doubtless a part. The whole breast is enlarged, and it sometimes is a partaker of the pain of the tumour, which is more like rheumatism than it is to any acute suffering. There are, however, periodic pains, which are occasionally exceedingly severe, but they do not occur except when menstruation is present, or the mind has been much disturbed. At a point near the nipple a small fluctuation is perceptible; the part is enlarged and of the size of a

walnut, the skin is bluish over it and very thin, the axilla is engaged. Miss B—— says her health is very good, and in every way perfectly regular; however, she is extremely pale and sallow, and I perceive she sometimes coughs, with little expectoration. She is cheerful and sleeps well.

The nature of this melancholy disease was sufficiently apparent. The breast and state of the axilla forbade an operation, while the slight cough, which did not attract her notice, to me bore evidence that the lung of that side was concerned. The case was hopeless. I could not say so to herself, and therefore I prescribed such mitigant treatment as was likely to be of service from time to time while she continued her visits at my house. At length she was obliged to give them over. She found the walk to oppress and hurry her breathing, and to give her a restless and troubled night.

The tumour now proceeded to shrink, but not by a suppurative inflammation, but by the rupture of little cysts or hydatids, which formed deep in the gland, and a thin, barely opaque fluid in copious quantity, showing their concealed size. The pains are much greater, and now they were variously described, while the surface of the tumour is free from much uneasiness or pain. As ulceration extends blood is sometimes discharged spontaneously, to the manifest relief of a sense of weight and fullness of the breast. The edges of the sore were slightly everted, but there was no cavity of much depth, such as Sir A. Cooper describes; perhaps, because the case proceeded so rapidly to a fatal close.

She was now troubled with great dyspnoea. She was easiest in semi-erect posture, which was prescribed night and day, always inclining to the diseased side. There is cough, but no expectoration. There are frequent spasms of the stomach and often vomiting.

Mr. Adams saw this case in its present stage. Nothing was done beyond pursuing the same course which had been adopted, with anodynes of one kind or other, and laurel water, and saline mixture to procure ease, and to prevent the vomiting. Soon after the arm began to swell, and was soon involved in a hard oedema, which was produced by the pressure exercised by the axillary glands, which were considerably enlarged. She had profuse sweats, which, at her wish, we endeavoured to prevent; in fact, she was now far advanced in phthisis. She retained all her faculties until the day before she died, being little more than three months from the time she first consulted me.

Sir A. Cooper observes, that "months and sometimes years roll on and the disease continues in its adhesive stage, and it often destroys without further change occurring." This is a truly just remark. I have a note of a Mrs. T——'s case of Upper Camden-street, who had this disease in its adhesive stage for more than twenty years, and she ultimately died of another affection. I also had occasionally under my care a Mrs. P——, who had this disease in its open ulcerated condition for fourteen years before it put a period to her existence.

#### HEAVY OR LOADED CATHETERS.

Since the year 1819, a memorable period, in which the late Mr. Wright and Mr. Daniell, with my friend Mr. Tagert, called on me to assist them in the deep emergency in which they were involved, by the operator (Mr. Wright) letting slip a gum-elastic tube which he was in the act of introducing into the bladder through the canula of the trocar used in paracentesis of that organ, as generally performed above the symphysis of the pubis, and I, descending by incision, separated the bladder from the posterior part of the pubis, as low as the crescentic junction of its anterior ligaments, and then incised it, though containing little fluid or not described the solid substance for which I was in search,\* I succeeded in the extraction of the canula, which was coiled and folded as a watch-spring upon itself; which circumstance marks the period as memor-

\* See Cases and Observations in Surgery. By J. Kirby, &c. Article, "Extraction of a Male Catheter from the Bladder by an Operation never before and never since Performed."

able, and thence I say that my mind was thoroughly impressed with the advantage of giving as much weight as I could to the catheters I possessed, whether silver or gum-elastic; and I have always advocated the use of a heavy or laden instrument as well adapted to find its way, unguided by much pressure, and even to overcome, if not hurried in the execution, a very permanent degree of indisputable spasm.

At first, these catheters were filled with lead, but each leaden stylet was provided with a very fine groove, that thus the urine might escape, and thus declare the instrument to have reached the bladder. Of late I have, in most instances, substituted gum-elastic tubes, without the usual openings near to their points. These aptly fitting, the catheter projects beyond its open extremity for from two to six inches, and admit both of an easy introduction and removal. The tube thus introduced into the catheter, I fill with quicksilver, and I afterwards see that it is properly stoppered.

Now this instrument has the advantage of considerable weight by which it enters the bladder, finding the course of the urethra, and permeating it without much difficulty, so that it arrives at its cavity without much guidance, and with more facility than the common catheter is found to do. When the part is in a state of comparative health its easy course may be readily conceived; but when there is stricture, it readily finds its way, and when once gets entry, makes a convenient curve, often much more efficient than the usual unsteady manoeuvre of applying its powers to overcome a spasm in cases of impermeable stricture.

#### ON DERMOID CYSTS AND PLASTIC HETEROTOPY IN GENERAL.

By M. LEBERT.

(Continued from page 376.)

##### DERMOID CYSTS OF SCROTUM.

Authors who have written on the subject, have reported cases where those cysts were found in the scrotum; notwithstanding, these cases are far from common. One of the most celebrated was that treated by Doctor Dietrich de Glogau; it was that of an infant which, shortly after birth, suffered first from difficult micturition, and afterwards from a tumour at the right side of the scrotum. When seven months old, the operation of circumcision was performed for a congenital phimosis and extirpation of the testicle, on account of the tumour which had increased considerably in size; it was four inches and three lines long, and two inches and four lines broad, and contained some quantity of bones of a true skeleton (pelvis, vertebrae, and long bones), as to leave no doubt as to its nature. The plate in the "Notices de Froriep," t. xiv., p. 15, shows in a most convincing manner an incomplete skeleton. This case occurs under different names in various works. We will now cite them, to obviate the bibliographical errors of the various authors who have mentioned this case. The original case was reported by Wendt of Breslau in his "Tabulæ Votivæ." Froriep makes mention of it twice in his "Notices," t. i., p. 287, and again t. xiv., p. 15. Friedlander describes it in the "Revue Médicale," t. viii., p. 361; and lastly, Michaelis mentions it in the "Journal de Gräfe."

Another case of undoubted inclusion occurs in the 13th volume of the "Notices" of Froriep, and was reported by Dr. Elk of Landshut. The subject of this case was a child of about a year old, born at Gilgenberg, in Austria, from which he extirpated a tumour five inches long by two and a half wide. The bones contained in the sac were manifestly those of a skeleton. The ribs, a dorsal spine, a thigh as far as the knee, an eye, &c., could be recognized.

Always admitting the well-established case of testicular inclusion, we believe that very often the question has not been examined with sufficient accuracy as to whether the contents of the sac were of new formation, or the debris of a fœtus. We will now mention some cases which will show to what extent this doubt is legitimate. Among the

more recent cases of inclusion, and one which has more particularly attracted the attention of pathologists, we will detail that one observed in 1840 at the Hôpital de la Charité by Professor Velpeau, and which M. Cruveilhier describes in his treatise on "Pathological Anatomy." The following is a succinct account of it:—The patient, named Gallochat (d'Esternay), who was 27 years of age, of a good constitution, suffered since his birth from a tumour at the right side of his scrotum, which, at the age of four months, was seen by Dr. Senoble, and which has not ceased to grow since. It is ovoid, hard, and of an osseous consistence in some parts, of the size of the fist, and situated behind and to the right side of the scrotum. The skin which covers it is whiter and thinner than that which surrounds it; it is completely insensible. There were several fistulous openings in it, through which fatty matter and hair came out. Of the tumour extirpated and dissected, M. Velpeau gives the following description: The external covering is cutaneous, as we have seen. In the interior were seen two small cysts containing albuminous matter, like the vitreous humour of the eye. A third cyst, about the size of a partridge's egg, containing a yellowish green matter, which M. Velpeau compares to meconium. A fourth sac surrounds a granular mass covered with hairs; and in this M. D'Arcet found epithelial scales and sebaceous matter. The fistulous opening of one of the cysts containing the green matter, allowed of the expulsion of a mass of hair, on which account this was compared to the anus. A number of articulated bones, one group of which resembled the scapula, clavicle, and humerus. Another larger, seems to be either the pelvis or the base of the skull. The third series seems to comprehend portions of the vertebra and indeterminate bones.

We find in this description only vague resemblances, without any precise anatomical characteristics. We would ask how it happens, that a fœtus becomes divided into cysts, and the meconium be separately encysted, whilst the pretended anus through which the hair was expelled constituted another fistulous cyst? There is, then, every reason to doubt, that in this case there was no fœtus; and besides, the osseous fragments united did not prove the existence of a skeleton, for we have seen that, even on this point, M. Velpeau is also vague. The fatty matter and the hair also are developed, as we have seen, under circumstances which would preclude the idea of inclusion. We will not enter on this discussion further here, seeing that we will return to the subject, when we treat of piliferous ovarian cysts.

M. Corvisart kindly communicated the following case, with a drawing, which had also been regarded as a case of inclusion, although the proofs appear to me to be entirely wanting in the following description, which I transcribe here literally:—"Arthur Berrot, aged twenty months, was born with something remarkable about his scrotum, but the woman who nursed him, and who was not the mother, was not able to give any particular account of it. This woman had him with her for two months. The scrotum of the child was then, she says, in the same state as it is at present; the little patient does not appear to be suffering. About a month ago the size appeared to increase somewhat. He was brought to M. Nelaton, who found an ovoid tumour, the size of a pigeon's egg, in the right side of the scrotum; the testicle appeared to be intimately connected with it. The tumour was hard, crimped here and there, transparent and indolent. A hydrocele was diagnosed, but a puncture made on the 19th of June, 1845, gave the sensation of various transverse septa; hardly any serosity escaped. On the 25th of June the tumour was extirpated, and the child recovered.

*Examination.*—The tumour was incised longitudinally. Although the spermatic cord was adherent to the tumour, there was no trace of testicle. The appearance of the tumour was not cancerous, but appeared to be formed of fatty masses, more or less compressed. Here and there a few cysts, containing a little serosity; examined by the microscope, it did not show any cancerous cells, fatty globules alone appeared.

The most remarkable appearances were the following :— Towards the inferior part was a sac containing numerous downy hairs, implanted in a white, hard, thick, dermoid tissue, forming a cup, which might be compared to hairy leather. Immediately adjoining is a second sac, containing hairs, stronger, longer, deeper coloured, analogous to the eyelashes.

Towards the centre of the tumour the knife grated on osseous points, and, on dissection, two triangular bones were discovered, situated right and left. Are these the scapulæ? On the right side was a long bone, articulated above and below with another long bone. To this last was articulated another long bone. Is there not here a humerus, an ulna, and a radius? A sort of aponeurosis or tendon, parts from the inferior extremity of the long bone, and is lost in the masses of fat on the right. On the left, it is united by an articulation to another long bone, and by another part with one of the triangular plates, which was slightly divided by a small cartilaginous portion being divided. Below, and to the right side, was found—first, a quadrilateral bone of a reddish colour, and below that a small osseous point, and finally, another above and behind this.

Above, and in the median line, a vesicle, containing serum was found, on which was implanted a long hair. Above the first triangular bone is a bone articulated with another, which bears on its superior part a beaklike process; a cyst is in the interior of these osseous expansions."

The above account describes, rather obscurely, and the exact drawing which accompanies it shows that there is a very distant resemblance; I should say an entirely imaginary one, with a fœtus, and minutely analyzed appears to be a collection of dermoid cysts, some of which contain hairs, and others unformed bones, united by cellular tissue.

By a little imagination, these pieces of bone might be compared to the bones of a skeleton, and their union by loose cellular tissue to articulations; for in true cases of inclusion the imagination has never such a vast field of interpretations of vague and insignificant resemblances; but the impartial observer immediately recognizes the fœtus in inclusions truly the result of conception.

A similar case, but still more instructive, is reported in the *Edinburgh Monthly Journal* by Mr. Goodsir. The following is a summary of it: The tumour and testis was excised by Mr. Duncan from a boy aged eight years. The testicle was much altered, and transformed into a fibrous tissue mixed with fat and grumous matter. Near the reflexion of the tunica vaginalis on the testicles, two club-shaped appendices were found covered with a cutaneous substance, and presenting thickly planted hairs, especially around the base. Some seemed even to proceed from the tunica vaginalis itself. In the substance of these cutaneous projections, especially in the larger, were soft masses of cartilage, with some vascular canals running through them. These cartilages are in part ossified, and in it may be recognized all the histologic elements of osseous tissue. Amongst the bones was one like an hour-glass, about half an inch in length. This is another case in which it would be impossible to refer the origin of the tumour to the result of conception. The tunica vaginalis gives origin to cutaneous projections, in the substance of which were found osseous and cartilaginous productions. We have before noticed under the head of enchondroma and cancer of the testicle, the great propensity of the testicle to enclose bones and cartilages; for our own part, we have met them in both scrofulous and cancerous testicle. All observant surgeons have confirmed this, and pathological museums are rich in cases of this kind. I also found an undoubted sebaceous cyst in a cancerous testicle. In a word, the testicle seems to partake, along with the ovary, of a very strong and varied heterotopic plastic force.

(To be continued.)

## CURE OF POPLITEAL ANEURISM BY COMPRESSION.

ROBERT S., aged 34, was admitted into Guy's Hospital, August 6, 1851, under the care of Mr. Poland, suffering from popliteal aneurism of the left leg. The patient is a wine cooper, and has been in the habit of lifting heavy weights; he belongs to a healthy family, and none of his relations have, to his knowledge, been affected with aneurism. The man is of temperate habits, and has all his life enjoyed very good health. About five months before admission, the patient was carrying a cask on his shoulder up some cellar-steps, he fell, and struck the inside of his left knee against a case or chest that was lying in the cellar; the cask, however, which he was carrying fell out of his way, and did not touch him. His leg was a little painful at the time, but he felt nothing of it afterwards. About three weeks after this accident, whilst tying his garter, the patient's attention was attracted to a painful swelling in the left ham. The tumour continued slowly to increase in size, but did not otherwise create any pain or inconvenience. A fortnight before admission, he for the first time observed a pulsation in the above-mentioned swelling, and during the night experienced some amount of uneasiness in the ham, as also shooting pains up and down the leg. The patient soon had the same unpleasant sensations during the day, especially when carrying a load. The tumour now inconvenienced him much, and when carrying things up the cellar, he was obliged to keep advancing with the right leg first, as he could not bear the weight of his left leg from the pain which it caused. From this time matters became gradually worse, but the man continued at his work till he was received into the hospital. He used to be able to walk, but the leg generally felt stiff during the first part of the morning, but this discomfort would commonly go off pretty soon.

On admission a pulsating tumour was observed in the popliteal region, on the left side, especially distinguishable when the leg was extended. It was of the size of an orange, and perfectly fluid. By pressure on the femoral artery not only did the pulsation cease, but the swelling would, by being slightly compressed, entirely disappear. Pressure upon the artery, below the tumour, caused the latter to become much more tense. A *bruit de souffle*, synchronous with the pulse at the wrist, was audible on a stethoscopic examination. No œdema of the leg or foot was noticed, but the superficial veins of the leg were congested: this latter symptom had, however, little value, the patient stated that the veins had been swelled for some years on both legs. As he was lying in bed, he complained only of a slight pain in the outer side of the popliteal region. The sounds and rhythm of the heart were normal, and the impulse is rather feeble; there was no cough, and no evidence of internal aneurism. Mr. Poland ordered infusion of digitalis in camphor mixture, and low diet.

On August the 9th (three days after admission), compression of the femoral artery by the clamp and pad was commenced. The leg was raised on a pillow and confined with sand-bags, so as to keep the limb at rest and relax the muscles, and oxide of zinc was dusted over the seats of pressure. The simple clamp instrument, somewhat modified, was applied over the femoral artery, just below the middle of the thigh, and the pulsations of the sac almost, but not entirely, arrested by the pressure. This was borne for an hour, when the patient complained of a little pain; a seven-pound weight was therefore placed on the artery in the groin, which contrivance completely commanded the pulsations, and thus allowed of the relaxation of the clamp. The man was now carefully instructed how to use the weight and instrument alternately, so as to relieve pain when necessary; he managed the apparatus perfectly, and the clamp came to control the artery more completely. It should, however, be noticed, that the weight at the groin commanded the artery with much more ease than the clamp, as the former did not give the patient so much pain as the latter. In the evening of this, the first day, the leg was warm, but felt numb below the knee, and also all over the

foot, except the toes. The leg was ordered to be wrapped up in flannel.

On the second day the sac was painful and tender to the touch; the weight acted well, but required to be held by an assistant, to relieve the patient, who could bear the weight for two hours, but the clamp only for twenty minutes or half an hour. His own feelings told him at once whether the pressure was properly applied or not, for when the circulation was controlled, he was much more free from pain in the swelling. This pain and tenderness were situated only on the outer part of the tumour, and diminished as the pressure was regularly used. The leg remained warm and somewhat numb. On the third day the patient had some sleep, as an assistant sat up and relieved him by holding the weight, which still acted admirably, and completely controlled the circulation. Pain down the leg was complained of, but the uneasiness in the sac was much less when the artery was completely under command. On the fourth day the sac had evidently become more solid, especially on the inner side, no pulsation being felt in that spot. There was much pain in the sac when the pressure on the artery was not complete. On the fifth day, Mr. Poland ordered four ounces of meat per diem; the tumour was getting harder. On the sixth day, the tumour was more solid, but still yielding to the fingers; it had lost all heat and tenderness; pressure was borne more patiently than heretofore, the more so as the improvement was manifest. On the twelfth day the patient could bear the clamp two, three, or four hours; he preferred it to the weight, and required no assistance at night; the groin was getting rather tender. On the fifteenth day the patient continued to manage the apparatus very well himself; the swelling in the ham was quite hard, not at all tender and painful, and when the pressure was removed from the artery, the tumour only appeared to move forwards, and not to dilate with the pulsations of the artery. On the twenty-first day the man began to show some impatience at being confined in his bed, though he still bore the pressure well; the sac was getting harder and smaller, but the sharp rough bruit, synchronous with the heart's pulsations, was still heard. Mr. Poland now directed that the digitalis mixture should be left off, and replaced by small doses of antimonial wine; the meat diet was continued. The pressure was also removed for an hour, and it was noticed that the pulsations of the sac had much decreased in force.

After this period the patient became guilty of a little carelessness. He was, however, on the forty-first day still progressing favourably; but the pulsations of the tumour were still evident on taking off pressure, though not perceptible until some minutes had elapsed; a few small arteries were now felt in front of the knee.

On the forty-eighth day the man's patience was almost exhausted; the tumour had become small and hard, but there still remained a slight pulsation on its outer side, which could easily be controlled by moderate pressure with the hand on the sac. Direct pressure upon the tumour was now tried by means of a small sand-bag placed over the swelling, the leg being allowed to rest upon it over the edge of the peg-box; pressure was thus exclusively made on the swelling without the establishment of collateral circulation being interfered with. On the sixty-fourth day the most moderate pressure was sufficient to arrest the circulation, and evident progress had been made; two large arteries were felt running over the sides of the sac. On the eighty-second day the pressure was intermitted for several hours daily. On the ninety-first day the sac was small and hard, but the circulation continued through the popliteal artery, communicating a pulsating feel to the aneurismal tumour. The patient was now allowed to get up during the day, and desired to wear the clamp outside his clothes; the pressure was, however, altogether omitted during the night. On the 102nd day the man left the hospital, with directions to use his clamp at night after leaving off his employment, which latter consists in superintending the packing of bottles. He could at the period of his discharge walk about without inconvenience, and had left off the clamp for three days, wearing only a small pad over

the tumour, fixed by a bandage. The swelling was then small and hard, of the size of a bantam's egg, with pulsations over the posterior part; but the beating was not felt laterally, and the sac does not dilate.

The directions given for the night were followed for a few weeks, and the patient then left off the instrument altogether. The man continued, however, to pay visits to Mr. Poland's house, once a month, up to September, 1852 (thirteen months after the treatment was commenced): he was carefully examined on each occasion, but no perceptible change in his condition was noticed. The patient improved in general health in the meantime, and continued his employment without any ill effect or inconvenience.

One month after this, the tumour was found hard and firm, about the size of a chestnut, and had pulsation communicated to it by the artery. The swelling felt like a gland lying over, and being adherent to the vessel; the pulsation not being the usual act of dilatation and distension, nor felt laterally, but only over the course of the artery. The sac was clearly consolidated by fibrinous deposits, but the artery was still pervious, not in the least obliterated, and it is very likely that the opening of the vessel into the sac was still patent.

On the 20th of October, ten months after his discharge, while the patient was lifting a truss of straw, his limb was in such a position that he produced much strain over the popliteal artery, and felt something give way in the locality of the tumour. The pain became suddenly very acute, but he continued with his work until obliged to desist, from the suffering endured in the leg. The patient now called upon Mr. Poland, with the idea that he had injured his joint, or was labouring under an attack of rheumatism. The knee was found extremely hot, painful, and much swollen, and the popliteal space filled with a tumour of the size of a bantam's egg, which pulsated freely in all directions. These pulsations were freely commanded in every direction, by slight pressure on the femoral artery. It was now evident that the popliteal trunk and old sac had suddenly given way at the former seat of injury, and that the present aneurism was the result of this second accident.

The patient was now re-admitted into Guy's Hospital, November 10, 1852, under the care of Mr. Hilton, just eleven months after his discharge. He was desired to use the same weight and clamp, and entrusted with the sole management of the treatment, as he was fully acquainted with the mechanism, from his former stay in the hospital. The clamp controlled the circulation in the vessel with slight pressure, and could be borne for several hours at a time without any intermission. On the loosening of the clamp, the weight was used in the groin. The patient could now sleep with the instrument fixed during the whole night, without any blood being allowed to flow through the artery. The pulsations in the sac stopped on the third day, but the treatment was pursued for three weeks, at the expiration of which perfect consolidation of the sac and obliteration of the artery were obtained. The patient left the hospital, December 7, 1852, in perfect health, twenty seven days after his second admission. The tumour was hard and solid, did not pulsate in the least, and was beginning to contract.

This case naturally suggests remarks of the most important kind touching the treatment of popliteal aneurism by compression. It seems, in the first place, rather strange that the cure which could not be obtained in the first portion of the treatment, by several months' perseverance, was accomplished, after the second admission, in less than three weeks. But as the aneurism was the result of an injury, it may be supposed that the opening in the popliteal artery communicating with the sac (probably situated on the outer side, where the pulsations and pain were always strongest), was, by the long-continued pressure, much reduced in size, though not completely stopped up; whilst the fibrinous layers within the sac were getting firm and compact. After the patient had been attending to his work for about ten months, a sudden jerk produced inflammation and great disturbance in the artery and sac; rest and pressure were now again used, and perfect consolidation and obliteration took place.

It is clear that this explanation cannot be supported by demonstrative proof; but if we may appeal to analogy, the correctness of this view will become apparent; and it is very likely that the vessel and aneurismal tumour would for a long time have continued to communicate, had the above mentioned jerk not taken place.

Dr. Bellingham, in his account of a case of this kind (DUBLIN MEDICAL PRESS, December 3, 1851), offers about the same explanation regarding the symptoms which have been described in this case—viz., continuance of pulsations, and diminution and induration of the sac. Dr. Bellingham says:—"In the details of this case, I have said that, after compression had been employed for a time upon the right lower extremity, it was discontinued before the pulsation of the aneurism had ceased, in consequence of the patient being obliged to return to his employment. Notwithstanding that the pulsation continued, the tumour not only did not increase subsequently, but actually diminished in size, although the patient had to work at a very laborious employment, in which he was obliged to lift and carry heavy weights; and during upwards of four years that intervened between the period at which the pressure was discontinued and the patient's death, it never caused the slightest inconvenience, and he continued to work until the enlargement of the thoracic aneurism compelled him to desist.

"The post-mortem examination shows why this was so; we find the aneurismal sac contracted and diminished in size, its parietes much thickened, and its cavity in great part filled up by fibrine deposited in concentric layers. A small portion of its interior still permitted the entrance of the blood which passed down the popliteal artery, the pulsation of which communicated to the sac gave the impulse which was felt at the part during the patient's life.

"It is a point of some interest to determine whether an external aneurism can be considered to be cured, although the channel of the artery at the seat of the disease is not obliterated, and a current of blood continues to pass through the vessel. We know that when aneurism of the arch of the aorta undergoes a spontaneous cure, the sac alone is filled up, while the artery for an obvious reason continues pervious afterwards. Now, the examination of this preparation, combined with the history of the case, afford evidence that popliteal aneurism may be so far cured that the sac can scarcely enlarge again, although there is no obliteration of the artery at the seat of the disease; and likewise that this desirable result may be brought about by making compression upon the artery on the cardiac side of the sac.

"It can scarcely, then, I think, be doubted, that aneurism in an extremity may be so far cured that it can neither enlarge again nor give way, although the blood continues to pass through the artery from which it springs, and an impulse continues to be felt at the part, owing to the pulsation of the artery being communicated to the sac. In the present case, there was an interval of above four years between the discontinuance of compression and the death of the patient, during which time, although the pulsation continued, the patient was able to follow a laborious employment, and never suffered the slightest inconvenience from the aneurism."—*Lancet*.

We rejoice to find that the London Surgeons begin to understand the treatment of aneurism by compression. Perhaps those of Paris may presently begin to think there is something in the practice.

CHOLERA.—The latest intelligence from Prussia is rather satisfactory as regards the progress of cholera, for although it has spread through the Polish territories, not only has its virulence abated, but the number of cases has also diminished. At Berlin three hospitals have been opened, and at Posen, from the 30th of July to the 29th of September, there were 2491 cases and 1233 deaths. All the public schools have been closed, and at Königsberg, M. Von Treschowitz and M. Waldow, connected with the legislature, have died. At Posen, the wife of M. Von Pattkamaner, the President, also died of cholera.

## ILLUSTRATIONS OF LARYNGEAL AND PHARYNGEAL DISEASES, WHICH ARE FREQUENTLY MISTAKEN FOR, OR ASSOCIATED WITH, PHTHISIS PULMONALIS.

By JOHN HUGHES BENNETT, M.D., F.R.S.E.,  
Professor of the Institutes of Medicine, and of Clinical  
Medicine, in the University of Edinburgh.

THE pharyngeal and laryngeal complications of phthisis pulmonalis are much more common than is generally supposed, and I believe that to them ought to be ascribed many of those symptoms which are generally attributed to the pulmonary lesion. Occasionally I have known laryngeal disease alone, mistaken and treated for phthisis; and when phthisis really exists, I have seen much benefit derived from a local treatment applied to the pharynx and larynx.

My attention was first directed to this subject by the following case:—

Case 1.—On the 11th December, 1849, Captain B. entered my room, to consult me regarding an occasional expectoration of blood, which caused him, but more especially his lady, much anxiety. He was a tall vigorous-looking man, between thirty and forty years of age, who had no cough or any complaint whatever, but from time to time had hawked up a small clot of blood about the size of a pea. On a few other occasions he had observed some mucous expectoration tinged or streaked with blood. His chest was finely developed, and its most careful examination failed to elicit anything abnormal. His appetite and digestive functions were excellent; and as commandant of a depot in the neighbourhood of Edinburgh, he had never experienced uneasiness from his professional duties. After repeated examination, I had no hesitation in stating that the lungs and large vessels were perfectly healthy, and that I hoped the expectoration of blood would cease spontaneously.

The origin of the blood in this case appeared to me at that time to be very mysterious. It was not florid. There was no reason to suppose it to be of pulmonary origin. There was nothing in his voice to indicate laryngeal disease. I did not examine the pharynx, not being then aware of the importance which ought to be attached to it. I was consequently left in great doubt as to the origin of the blood, and of the best means of removing anxiety from my patient. My uncertainty, however, was partly dispelled by the following case:—

Case 2.—I was requested by an assurance office, in July, 1850, to examine the chest of Mr. M., a merchant, aged about 30, who said he laboured under no kind of complaint, with the exception of occasional sore throat, and expectoration of mucus tinged with blood. He was tolerably stout, took long walks without uneasiness, and suffered from no difficulty of respiration or from cough. Repeated examination of his chest failed to elicit any physical sign indicative of pulmonary disease. I therefore certified that his lungs were healthy. In October, 1851, this gentleman called upon me again for advice, under the following circumstances. The soreness of the throat had latterly increased, and considerable cough was induced, after which he spit up mouthfuls of purulent matter, frequently tinged of a red colour. He brought me some of this sputum to examine, which consisted of mixed blood and pus, of a dirty brick-red colour. Examination of his chest again convinced me that the lungs were unaffected; but in the interval I had paid attention to the writings and practice of Dr. Horace Green of New York; and I now examined his throat, when the cause of his symptoms was at once apparent. The fauces and upper part of the pharynx were studded over with nodular swellings, varying in size from a pin head to that of a pea. Many of them were bright red and fungoid in character, probably the origin of the extravasated blood, whilst considerable patches of purulent matter adhered to several parts of the mucous membrane. I applied a sponge, saturated with a strong solution of the nitrate of silver to the affected parts. In three days he returned, having been much relieved, when the application was repeated. I have not seen him since.

These two cases convinced me that certain symptoms which have hitherto been considered as indicative of phthisis might have their origin entirely in the fauces, pharynx, and upper part of the larynx. The cough so occasioned, with the purulent expectoration, often tinged with blood, frequently so resembles that occasioned by phthisis, as not only to induce alarm in the minds of the patients, but frequently to mislead the medical practitioner. I have now met with many such cases, which have been mistaken for phthisis, and which have been treated for that disease without any effect, until local remedies were applied, when they, for the most part, disappeared, or became much better.

The following case illustrates still further the occasional similitude of laryngeal disease to phthisis pulmonalis, and the erroneous treatment to which error in diagnosis may lead.

*Case 3.*—Margaret Dickie, a staymaker, æt. 25, admitted to the Royal Infirmary, Sept. 9, 1851, labouring under occasional vomiting, frequent cough with hæmoptysis, and copious purulent expectoration. There was considerable sweating at night, and her general health, owing to want of sleep and the harassing cough, was much broken down. At the commencement of the winter session in November, I found her taking an acid mixture to relieve the sweating, a cough mixture to diminish the cough, together with cod-liver oil. The chest had also been blistered. Careful percussion and auscultation convinced me that the thoracic physical signs were perfectly normal. I then examined the fauces, which were covered with purulent mucus, but presenting here and there red and prominent follicles. The cough was also ascertained to be convulsive, the voice hoarse and broken, and, on placing the stethoscope over the larynx, a loud ringing sound accompanied the inspiration. From these facts I had no difficulty in diagnosing laryngitis; and on ascertaining that the woman was a prostitute, and addicted to drink, there could be little doubt that it was of syphilitic origin. The fauces were freely touched with a solution of nitrate of silver (3ss. to ʒj. of water). This was repeated on the following day, and on the next the upper part of the glottis was touched, causing severe convulsive cough. I subsequently passed the sponge, saturated with the solution, into the larynx every second or third day during the month of November, which at first caused very severe and prolonged convulsive cough, that gradually became somewhat diminished. On the whole, however, no great amendment was produced, although the expectoration and cough during the intervals were lessened. The local applications were then suspended, but it soon appeared that they had been beneficial in checking the symptoms, from their severity again increasing, especially the amount of expectoration streaked with blood, and the want of sleep at night, owing to the severity of the cough. In the second week of December, therefore, the topical applications were resumed, together with occasional blisters to the larynx, and once more a certain amount of benefit was obtained. But as this treatment, combined with the internal administration of iodide of potassium and bitter infusions, for a period of four weeks, seemed to produce no further improvement, she was dismissed on January 7, 1852.

In this case all the symptoms of phthisis pulmonalis were present, including emaciation, profuse sweating, cough, expectoration of pus mingled with blood, bad appetite, hectic, and in consequence cod-liver oil, cough mixtures, acid drops, wine and good diet were administered, and all without effect. Indeed her appetite was so bad, that the diet was not taken, and nutrition suffered. When a careful examination of the chest enabled me to form a correct diagnosis, the treatment was changed. The cough and acid mixtures were abolished, the stomach gradually regained its tone, her appearance slowly improved, and although, from necrosis of the ossified cartilages, the local disease was not removed, it was considerably benefited by topical applications.

*Case 4.*—Miss G., æt. 56, had been treated by a homœopathic practitioner, for three years, who informed her that

she was labouring under consumption, and at last that she had better go to Australia. Her friends, unwilling that this sentence of banishment should be carried out without further advice, brought her to me on the 19th of October last. I failed to discover the slightest alteration of the lungs, either by percussion or auscultation. On the contrary, repeated examination convinced me that the inspiratory and expiratory murmurs both possessed their natural softness and duration. There was, however, frequent cough with copious purulent expectoration. She had had constant sore throat since her childhood, and was labouring, in addition, under headaches, loss of appetite, constipation, leucorrhœa, excessive menstruation, hæmorrhoids, occasioning frequent hæmorrhage, so that she presented the anemic appearance, with all the symptoms of confirmed chlorosis.

When I informed her that her lungs were not diseased, and that her cough entirely depended on some affection of the throat, she could not believe me. She had so long been convinced that her case was one of consumption, and that nothing but a change of climate could be of any advantage to her, that I think it was with some reluctance she heard a different opinion advanced. To oblige her relations, however, she allowed me to apply the solution of nitrate of silver, first to the fauces and subsequently down the œsophagus. She then became convinced that there was a spot at the upper part of the throat which, when touched, gave rise to burning pain, induced severe spasms for a few moments, and subsequently left her free from cough, and enjoying remarkable ease. The applications were consequently continued every other day, and were conjoined with the internal administration of iron and vegetable bitters. Under this treatment she has much improved in health. I soon perceived, on passing the sponge, that there was a constriction at the upper part of the œsophagus, which I attribute to long-continued ulceration, followed by contraction, the termination of which causes me considerable anxiety.

Even when the lungs are decidedly tubercular, much of the cough and irritation may be owing to laryngeal complication, although, in the majority of cases, they are attributed to the pulmonary disease. I am satisfied that the constant cough and succussion of the chest so occasioned increases, if it does not actually sometimes induce, pulmonary disease, especially the most common of all phthisical complications—bronchitis. I was very much struck with the amount of cough in the following case, which was removed by paying attention to the laryngeal complication.

*Case 5.*—Dr. C., a medical man, aged about 25, had long suffered from delicate health, and latterly the fatigue of his practice, which necessitated long journeys on horseback, frequently in the middle of the night, had induced constant coughing and thoracic pain. He had found such remedies as cod-liver oil, expectorants, demulcents, and anodynes useless. On examining his chest, there was slight dulness on percussion under one clavicle, somewhat harsh inspiration, and prolonged expiration in the same situation, with a little increase of vocal resonance. The disease in this case was evidently incipient, and yet I noticed the violent suffocative cough, followed by expectoration of purulent mucus, and was struck with the evident disparity between the incipient pulmonary lesion and the advanced cough and expectoration. This was explained by inspection of the fauces, which were red, rugous, and covered with patches of pus. Further, it was clear from the symptoms that the glottis was also affected. The local application every other day of a sponge saturated in a solution of nitrate of silver, was soon followed by the best results, and in a few weeks the cough entirely ceased, and with good diet he regained his general health, although the pulmonary signs remained unchanged.

The removal of the cough and expectoration in this case, although incipient phthisis was undoubtedly present, proves that the former were in no way caused by the latter, which continued to remain, notwithstanding the disappearance of his distressing symptoms. Expectorant and anodyne re-

medies in such cases are evidently useless and even injurious. Useless, because it cannot be supposed that squills, ipecacuanha, &c., by being introduced into the stomach, can act upon the follicular disease of the pharynx and larynx; and injurious, because these remedies, combined as they usually are with opium, occasion nausea, derange the appetite, destroy the capacity of taking food, and thus cause that diminution of vigour in the patient, so favourable to the development of the pulmonary tubercular exudation. In the following instance even a better result was obtained.

*Case 6.*—Dr. B., *æt.* 34, a medical practitioner in the island of Surinam, applied to me, during a visit he made to this country, in June, 1850. He had frequent cough and sore throat, with copious expectoration, increased by exposure to cold. There were also the usual symptoms of incipient phthisis. On examining his chest physically, I discovered comparative dulness under the right clavicle, slight crepitation with the inspiration, prolonged expiration, with marked increase of the vocal resonance; the left lung was healthy; the mucous membrane of the fauces was of a dark red colour, scattered over with prominent follicles. I applied the sponge first to the fauces and afterwards introduced it into the larynx every other day, with evident benefit. He also took cod-liver oil, with an alkaline and vegetable bitter mixture. In the autumn he returned to Surinam, and soon afterwards informed me by letter that his health was greatly improved. He again visited Edinburgh in August, 1851. The throat had latterly again become troublesome, from exposure to the inclemency of the weather; but on examining the chest, although there was still slight dulness and increased vocal resonance under the right clavicle, all crepitation had disappeared. He spent the following winter at Sligo, and this summer commenced practice in a large village in Perthshire. Last month he again visited me, and asked if he could venture to insure his life. On percussing the chest no dulness could now be discovered, a mere shade of increased vocal resonance remained, and the breath sounds were perfectly natural. Under these circumstances I considered his phthisis to be arrested, and had no hesitation in sanctioning his application to an Edinburgh life insurance company, which at once admitted him, without any extra premium. Now I am of opinion that the arrestment of the phthisis in this case was mainly due to the good effects of the applications applied to the pharynx and larynx, and that the diminution of irritation there, and the removal of the cough, enabled the exuded tubercle to become absorbed with more readiness than it would otherwise have done.

I could cite a considerable number of cases in which laryngeal symptoms have been more or less mistaken, for or complicated with phthisis, and which have been greatly benefited by a local treatment. At the same time, I need not say that there are a large number of cases in which no such complication exists, and that they must be judged of only by a careful auscultatory examination of the lungs and larynx, and by inspection of the pharynx. I have also had abundant opportunities of satisfying myself that many so-called cases of chronic bronchitis in persons of advanced life are entirely owing to throat disease,—a point, however, which has been so ably illustrated by Dr. Horace Green, that I need not dwell upon it here.

The propriety of local applications in cases of tubercular ulceration of the glottis or larynx has in this country been much doubted, although highly recommended by Dr. H. Green. The following case, in which the larynx was greatly involved, has served to persuade me of its occasional benefit:—

*Case 7.*—Mr. P., an advocate, spent the winter of 1851–2 at Torquay, and consulted me in March following. He was aged 39, and told me, in a hoarse whisper, that for three or four winters previously he had suffered from cough, with discharge of matter from the nose. During the summer he was quite well. While resident in Devonshire he gradually lost his voice, and his medical attendant there

had passed a sponge saturated with a solution of nitrate of silver every day,—a treatment, however, that had failed to arrest the aphonia, which, when I saw him, was complete. On examining his chest, I ascertained that there was impaired resonance under both clavicles, harsh and blowing murmur on inspiration, which, with spitting, left little doubt that the pulmonary organs had been long affected, but were now in a quiescent state. His countenance was expressive of much suffering; there was considerable emaciation, great weakness, much sweating; and he complained of almost constant spasmodic cough, which shook the entire frame. There was pain and dryness of the larynx and throat, frequent expectoration of purulent mucus, often streaked with blood. Difficult deglutition, especially of fluids, which never failed to excite cough and prolonged spasms. On placing the stethoscope over the larynx, inspiration was accompanied with a hoarse sound; and on inspecting the fauces and pharynx, the mucous surface was seen to be rough, sprinkled over with red prominent follicles, and streaked with adherent purulent mucus.

As this gentleman assured me that the sponge had been daily passed into the larynx by his medical attendant at Torquay, I did not hesitate to introduce it at my first visit. There followed, however, the most violent general spasms, the greatest difficulty in inspiration, rendering suffocation imminent, and then prolonged cough shaking the body, accompanied with purulent expectoration tinged with blood. The violence of the spasm somewhat abated in from two to three minutes, but he was unable to address me for ten minutes more. He then said that he had never experienced similar sensations previously, and was satisfied that the sponge had never been introduced into the larynx at Torquay, as he had been informed that it had by his medical attendant there. On visiting him the next day, I learned that the local application had been productive of the best effects, that the cough and spasms had entirely ceased, deglutition had been performed with more ease, and that he had passed a better night than he had enjoyed for many months. His appetite, I understood, was anything but good, and he had for a long time laboured under dyspeptic symptoms. I recommended him to remain quiet, not to speak, and to take a nutritious solid diet. In the course of the night the cough and spasms returned, and next day I again passed the sponge, which once more excited spasms and suffocation, but not to so great an extent as on the former occasion. I continued to pass the sponge every other day, and its good effects were well marked. In a fortnight it excited little irritation, and was invariably succeeded by a sense of ease, diminution of cough, which generally continued to the following night. He was now also enabled to swallow his food with more comfort and more abundantly, and in consequence his general strength was slowly improving. During the months of April and May, the local application was continued every second or third day. Towards the end of that month he was enabled to take short walks, and instead of my going to him at Morningside, he came into Edinburgh and visited me. I had great difficulty, however, in preventing him from endeavouring to speak, and he was continually exciting the vocal cords. Indeed there could be little doubt that the voice, though not distinct, was much better, and occasionally, on making an effort, he was pleased to hear himself utter articulate sounds. He now changed his residence, and it is presumed, from having slept in a damp bed-room, or from some other cause, a fresh attack of laryngitis was produced, attended with return of the cough, pain in the throat, and spasms, with fever and great restlessness at night. The pain was sometimes most severe on the right, at others on the left side, but was diminished by counter-irritants, and afterwards by the local application. In the middle of June, I found it impossible to pass the sponge fairly into the larynx, and it was singular to observe that the patient became worse, felt more pain, and especially complained of pain extending back to the ear. It was apparent to me, however, that the ulcerated surface was cicatrizing, although I felt some difficulty in understand-

ing how the glottis was impenetrable. It then occurred to me that probably fungous granulations were obstructing the orifice. One day towards the end of June, he told me that on making a deep inspiration he felt something vibrating at the orifice of the larynx, and it then appeared to me probable that a small polypus had formed there. A few days afterwards, in attempting to pass the sponge, it was ascertained that this was really the case, and he immediately spat up a fleshy mass, the size of a pea, with a small neck at one side. The next day the sponge entered as usual, without any difficulty, and continued to do so till the middle of July, when it again met with an obstruction. His general health, however, had greatly improved; the appetite was tolerably good; the pulmonary signs throughout had remained stationary. In the early part of August, he went to the country on a visit, and his health became much improved. During September he visited a hydropathic establishment, and submitted to a course of treatment, consisting of a wet sheet every morning, a sitz bath twice a day, a wet belt round his abdomen worn from morning until dinner time, and a saturated towel round his throat every evening, with walking three times a day in spite of all weathers. This heroic treatment caused the sweating and weakness, which had previously disappeared, again to return. He felt shivering on one occasion, after the sitz bath, and acute pain in the chest, violent cough and epistaxis, which fortunately subsided next day. On my seeing him early in October, he was pale, thinner than I left him, the voice, throat, and larynx were in the same condition; but he expressed himself as having been relieved of his occasional headache and dyspepsia. Towards the latter end of October, however, he complained of severe pain, deep in the nostrils, extending in the direction of the frontal sinus, and backwards to the ear on the left side. This continued to increase, and the discharge from the nose became more abundant, and formed inspissated moulds in the nares during the night, which were with difficulty discharged on the following morning. During the present month (November), two pieces of laminated bone have been discharged at different times, one from the left nostril, the other by the mouth, it having fallen backwards into the throat. At this juncture I thought it possible that surgical interference might facilitate the removal of a sequestrum, should one be present in the nasal passages, and on stating this to the patient, he requested me to consult with Mr. Syme on that point. The opinion of that gentleman was that the vomer was the bone diseased, and that no surgical interference was warrantable.

Such is the present condition of this case, which I regard as one of arrested pulmonary and laryngeal phthisis, complicated latterly with ulceration and necrosis of the nasal passages. The latter is the only active disease under which he now labours, and is the source of the slight pharyngeal cough which still lingers. The local treatment of the larynx has, to use his own expression, "made him a new man,"—and it is in this respect that the case is instructive. No doubt the severity of the hydropathic treatment exposed him to unnecessary risk; for had a fresh inflammation seized either upon his larynx or lungs, it would have been most injurious, if not fatal, and it must be obvious he very narrowly escaped this. On the other hand, his general health was no way improved by it, if we except the better appetite, dependent probably on the increased amount of exercise he was induced to take.

The cases now given have satisfied me that lesions of the pharynx and larynx ought to occupy the serious attention of practitioners in all cases of pulmonary diseases, and that the following conclusions may be drawn from them:—1st, that not unfrequently diseases, entirely seated in the larynx or pharynx, are mistaken for phthisis pulmonalis; 2nd, that even when pulmonary phthisis exists, many of the urgent symptoms are not so much owing to disease in the lung as to the pharyngeal and laryngeal complications; 3rd, that a local treatment may not only remove or alleviate these complications, but that, in conjunction with general remedies, it tends in a marked manner to induce arrestment of the pulmonary disease.—*Edin. Monthly Jr.*

## TWO CASES OF OPHTHALMITIS—ONE TRAUMATIC, THE OTHER IDIOPATHIC.

By HENRY HOWARD, M.R.C.S.L.,

Ophthalmic and Aural Surgeon and Clinical Lecturer to St. Patrick's Hospital, Montreal, &c. &c.

ON the 8th October, 1851, Mrs. B. brought her daughter, Miss B., aged 11, to consult me about her right eye, which had been perfectly blind for five years. The only history of the case that either mother or child could give was, that five years previously, by an accidental circumstance, it was discovered that the child was blind of one eye. The child never remembered having had any pain, and the mother was sure that the child never had any sort of a sore eye. If the strong light of a candle or the direct rays of the sun were brought upon her eye, she perceived light, but this was all. Her general health was perfectly good, although there existed all the signs of a strumous diathesis. The left eye was perfectly healthy; colour of iris blue. The mother was positive that there was nothing the matter with the child's eye when three or four years old. On examining the eye the only abnormal appearance that I could observe was, that the pupil was very small, of nearly a triangular shape, and blocked up with organized lymph; in fact, pure lymphatic cataract, presenting all the appearance to be found in a case the result of long-continued inflammation. The iris was something of a darker colour than that of the healthy eye, having rather a greenish hue. There was no increased vascularity in any part of the eyeball. I ordered the child a dose of purgative medicine that day, and on the next day I operated with the needle, through the cornea, with which I divided in pieces the lymph in the pupil, and afterwards a soft cataract which I found behind it. The ordinary treatment after such operations was adopted. It was followed by slight inflammation, and at the termination of six weeks, there was a tolerably fair-sized pupil, and sight much improved. There were yet, however, some bands of lymph crossing the pupil. There being no more improvement after two months than there was after the expiration of six weeks, I again operated in the same way, dividing the remaining bands of lymph. The same after-treatment was adopted, but on the third day traumatic inflammation supervened, the iris was perfectly green, and bloodvessels could be seen to traverse it even with the naked eye. The sclerotic was of a dark red colour, every part of it injected with blood, yet there was no pain, nor the slightest intolerance of light, and the child herself was perfectly unconscious that there was anything wrong, more than that she could not see so well as before I last operated. I put her upon calomel and quinine, one grain of the former and half a grain of the latter, every six hours. In three days mercurial fetor supervened, which action I kept up for a week by giving one grain of calomel every night; during the same week she took one grain of quinine in solution three times a day. At the termination of a fortnight all inflammation disappeared; absorption went on, and she received tolerably fair vision with nearly a circular pupil.

Case 2.—J. Q., a labourer, aged 40, received into the ophthalmic ward of St. Patrick's Hospital, April 20, 1852, stated that he had been under the care of Dr. —, for six months, for disease of his eyes, that for the first fortnight he suffered some pain in his eyes and slight pain in his forehead, but since that time he only suffered from scalding tears, and the pain caused by exposing his eyes to light. That for the last three months he could only discover light from darkness. During the six months he had used a great many bottles of wash for his eyes, but never took any medicine. On examination, I found that he could not observe my hand move between him and the window, yet he complained of intolerance of light when his eyes were opened and exposed to it. The sclerotic coat was of a deep red colour. The pupils were contracted to almost the size of a pin's head, and blocked up with lymph. Vessels could be distinctly seen traversing the surface of the iris, and crossing the lymph in the pupil.

The anterior surface of the iris was convex, and nearly in contact with the cornea, thereby obliterating the outer chambers of the eye. I must confess that I had but little hopes of benefiting this man, as from the history of the case, together with the appearance of the eye, I feared much that the retina had been either disorganized, or covered with lymph. I determined, however, to give the case a trial, and at once put him, after well purging him, upon one grain of calomel and half a grain of quinine every six hours, and applied extract of belladonna round his orbit once a day. On the twelfth day he was salivated, but from the sixth the inflammation began to subside and his vision to improve; the pupils about as large again as when he came into hospital; no intolerance of light. I kept his mouth sore for twelve days longer, by giving him one grain of calomel every night, and sometimes twice a day, during which time he took one grain of quinine in solution four times in a day. At the end of this time the pupils were about four times as large as they were when he came under my care; they were in shape very similar to the leaf of a shamrock or clover. The greatest part of the lymph was absorbed; but there were yet some bands crossing the pupil. I then put him upon the solution of biniodide of mercury ten drops three times a day (every ten drops of this solution contained the one-tenth of a grain of the biniodide of mercury), which treatment, with the daily application of the extract of belladonna round the orbits, I continued till the 12th of May, twenty-two days after his admission. At this period the iris began to lose its convexity, and the anterior chamber of the eye, consequently, too became large and of a normal appearance. The sclerotic coat had become perfectly white, and no more vessels were observable traversing the iris. One band of lymph remained across the left pupil, but none in the right. He could distinguish the different persons in the ward with him. His mouth having been kept slightly sore up to this time, I discontinued the biniodide of mercury and put him upon the hydriodate of potass, ten grains every eight hours. I also ordered his diet to be improved from soup to meat once a day. On the 25th of May, I discharged him from hospital, being at the time able to see the houses on the opposite side of the river from the window of the hospital—a distance, I should suppose, of two miles. This man called to see me early in the present month, and he stated that his sight was improving every day, so that he could then see nearly as well as ever he did. His eyes presented a very healthy appearance, with the exception that the pupils were irregular, and a slight band of lymph was still visible across the left pupil.

I consider these two cases of importance—first, because they prove how such inflammation of the eyes may go on so as to destroy vision, and yet present few of the diagnostic symptoms; secondly, the necessity of carefully examining the eyes when dimness of vision is complained of; thirdly, the necessity of a correct diagnosis; and fourthly, these cases prove how much disease the eyes will sometimes bear without being destroyed, and I consider the last case is a most satisfactory proof, that under certain circumstances even organized lymph will be absorbed by properly directed treatment.—*Canada Med. Jour.*

#### HÆMORRHAGE FROM THE EXTRACTION OF A TOOTH.

By S. A. SALTONSTALL, D.D.S., Columbus.

BELIEVING it to be quite common to report cases of interest in whatever department of our profession they may occur, I wish to communicate, in as few words as possible, the particulars of an extraordinary case of hæmorrhage which followed the extraction of the first bicuspid tooth on the right side of the upper jaw.

The subject was Mr. B.—of this place, a member of one of our best families, and a young man of superior attainments, and one of whom much of usefulness was anticipated in the future. I report the case at his own request, as he has recently returned from New York with the title of M.D. After removing the tooth and using a pledget of

cotton saturated with alcohol and pulverized alum, the bleeding, though profuse at the time of the application, ceased, and the patient left my office. Late in the evening the orifice began to emit a copious discharge of blood, and I was sent for to visit him at his father's residence. I used the cork and cotton, which checked for the time the flow of blood. The compression was ordered to be continued until the healing process should indicate the safety of removing it. On the second morning about day-light I was sent for with the word "Mas, John gwine to die." I then used the pure nitrate of silver, which afforded only temporary relief. Finding that this would not do I used sulphuric acid, first protecting the teeth with beeswax; this failed. I then proposed to apply the actual cautery in the usual way, which was objected to by the consulting physician, who argued that upon its removal it would bring away with it the coagulum, and only serve to increase the hæmorrhage. I began to think that my career as dental surgeon was to end very speedily. The father of the patient was now considerably alarmed, and said to me, "you must do something." At this moment an idea occurred to me that might probably succeed. I mentioned it, and all concurred that it would certainly do; the young man consented to submit to it. I took a piece of pure silver plate, and cut it in shape to fit between the teeth and cover the lips of the orifice about the eighth of an inch on each side. This was bent to fit the parts and heated to a white heat, and suddenly applied to the place, where it remained for several days. When it was removed, the coagulum came away with it. The orifice was examined, and a very delicate covering, resembling tissue paper, had formed over it. The success of this operation is mainly attributable to the firmness and presence of mind manifested by the patient. I took my position immediately in front of him, with an instrument bent the right shape to hold the silver, and held it in my left hand; then with an ordinary mouth blow-pipe and a spirit lamp, I applied the heat until the silver was sufficiently hot, while the patient held a napkin firmly over the orifice. At a signal understood by him, he removed the napkin, and I applied the red-hot silver, which arrested effectually the hæmorrhage.—*Amer. Jr. of Dent. Sci.*

#### ADHESIVE PLASTER AS A MEANS OF MAKING EXTENSION IN THE COMPOUND AND OTHER FRACTURES OF THE LOWER EXTREMITY.

By S. D. GROSS, M.D.,

Professor of Surgery in the University of Louisville, U.S.

WILL you be so kind as to grant me a little space in your valuable journal for a few remarks on the subject of adhesive plaster, as a means of making extension in compound and other fractures of the inferior extremity? I am induced to ask this favour, because the origin of this mode of treatment, which has lately attracted considerable attention, and which has been adopted with great advantage, in several sections of our country, has been ascribed to a gentleman who is in nowise entitled to the credit of it, if credit it deserves.

In my work on the "Anatomy, Physiology, and Diseases of the Bones and Joints," composed within a few months after I was invested with the honours of the Doctorate, and published in Philadelphia in the summer of 1830, is the following passage:—"In complicated fractures of the leg, it not infrequently happens that the soft parts about the ankle are so much contused, or otherwise injured, as to render it impossible to employ the usual extending bands. When this is found to be the case, the difficulty may usually be remedied by applying along each side of the leg, as high up as the seat of the fracture will admit, a piece of strong muslin, about two feet and a half in length, two inches and a half in width, and spread at one of its extremities with adhesive plaster. The part which is applied upon the limb should be confined by three or four circular strips, so as to keep it firmly in its place, and equalize the extending power. The free extremities of the extending bands should then be tied under the sole of the foot, and be secured to the block or bar which connects the lower ends of the splints. This mode of making extension, for which we are indebted to the ingenuity of my friend and preceptor, Dr. Swift of this place, will, I am fully persuaded, be found highly useful in practice, and satisfactorily obviate the inconveniences to which I have alluded."

At the time of writing the work here quoted, I was spending a few months at Easton, Pennsylvania, where I had an opportunity of witnessing the excellent effects of this mode of management. Since that period I have omitted no opportunity of employing it in my own practice; and I have never

failed, during the last thirteen years, to speak of it prominently before my classes in the University of Louisville.

Dr. Sargent, in his excellent little work on "Bandaging and other Operations of Minor Surgery," ascribes the credit of this method of extension to Dr. Wallace of Philadelphia; and the same statement is reiterated in that gentlemen's edition of Dr. Cruikshank's "Surgery," published at Philadelphia in 1848.

Within the last two years, Dr. Crosby of New Hampshire, has published a short account of this mode of treatment in the *New Hampshire Journal of Medicine*, illustrated by several cases, in which it appears to have been adopted with the happiest effect. In one of these, a compound fracture of the tibia and fibula, the counter-extending band was applied to the upper part of the leg, and the extending band to the lower part of the leg and foot; the plan answered most admirably, and caused not the slightest inconvenience to the patient. Dr. Crosby states that he healed two cases of fracture of the clavicle in children two years of age, with nothing but adhesive strips, with as good success as he ever had with the old methods, and with half the trouble. The same mode of treatment has been lately employed with great success in the New York Hospital in fractures of the inferior extremities.

My conviction is that this plan of making extension deserves to be much more extensively employed than it has hitherto been by my professional brethren. It is particularly applicable to compound and complicated fractures of the leg, but it may also be advantageously resorted to in all cases of fracture of the leg and thigh, in which, on account of injury, excoriation, disease, or excessive morbid sensibility of the ankle, heel, or instep, it is impossible to use the ordinary extending means.

The limb should always, as a matter of course, be shaved before the bands are applied; and the substance of which these bands are composed should be of the most pliant and unyielding character. The adhesive plaster should also be of a very superior quality. The circular strips should not completely encircle the limb, lest they impede the return of the venous blood, and the leg should be carefully bandaged from the toes up.—*Philadelphia Medical Examiner*.

#### DEATH FROM CHLOROFORM.

A PERSON named Henry Hollingworth, a factory operative from Newton-moor, near Hyde, has fallen a victim, at the Manchester Royal Infirmary, to the use of chloroform, administered to nullify the pain consequent upon a severe operation. An inquest was held on view of the body by Mr. Herford, coroner for the borough, when the following evidence was given:—Mr. J. W. Baker, house-surgeon at the Royal Infirmary, said the deceased was admitted on the 16th December, on account of a malignant tumour on the right thigh, to remove which an operation was performed, as it was looked upon as a cancerous tumour, though enveloped in much doubt, as those tumours often are. He was in a bad state of health when admitted, and everything was done to improve his health previous to the operation. A consultation, as I understood, had been held previous to his admission, and it had then been determined that the operation should be performed, of course with the consent of the patient. The consultation was of all the medical men of the infirmary. The deceased the day before the operation said he was ready for it, but wished to have chloroform. Almost every patient takes it. I said he should have it if he wished it, and that he would feel no pain, and that I would do all I could to support his strength. I did not give him any caution. We have given chloroform frequently, and never had a fatal case before. At eleven o'clock on Friday, the 24th December, the operation took place. There were present Mr. Jordan, as the operator, Mr. Peever, as his assistant in the operation, Mr. Wilson, Dr. Renaud, and Dr. Wilkinson (all members of the honorary medical staff of the infirmary), and myself. Mr. F. Heath, a qualified surgeon, administered the chloroform. The man was very much excited, struggled, and talked fast. The chloroform was administered slowly, and every precaution was taken to prevent any danger; and the medical men remarked two or three times how very long it was in taking effect. He at last became insensible in about seven minutes at least. Mr. Jordan commenced the operation by an incision into the skin covering the tumour. I was assisting the surgeon when Mr. Heath directed my attention to the patient's face. This was about five minutes after the operation had commenced. I then observed congestion about the face, but there was no stertorous breathing. His pupils appeared almost to have ceased to act. His breathing was becoming exceedingly slow, and he seemed to be sinking fast. I directed the attention of the operator and other medical men to these

symptoms. The operation was then suspended, and means resorted to for restoring animation, but the pupils had ceased to act, and had become fixed almost immediately. He gave one strong gasp, and then to all appearance was dead. In administering the chloroform successive doses were given until it took effect. Every dose consisted of a drachm, taken at intervals in an inhaler. Constitutions differ with regard to the effect produced by chloroform, but we use every precaution to prevent injury, and I am satisfied that the surgeons did their duty in the administration of the chloroform and in the operation.

Mr. Jordan was examined, and stated, in corroboration of Mr. Baker's evidence, that more time elapsed than usual before insensibility was produced, and then it was not complete, for after the incision was made, the man, more than once, said a cat was scratching him. Chloroform was generally administered in cases of operation, unless there were circumstances which, in the opinion of the surgeons, rendered it undesirable. Mr. Heath was a competent person to administer chloroform. The post-mortem examination showed that asphyxia, caused by chloroform, produced the death. There was a congestion both of the brain and lungs.

Verdict—"Died from the effects of chloroform."

#### CONVULSIONS CURED BY LANCING THE GUMS.

By V. M. SWAZEY, D.D.S.

IN July, 1847, while on a visit to some relations in Canada, I was requested by Mr. S., who had called at my uncle's with whom I was staying, to visit a child of his, which had been sick for several weeks, and the symptoms were becoming more and more aggravated every day. During the last three or four days, it had had several convulsions. The illness was supposed to result from teething. When I saw the child, the parents had nearly despaired of its recovery.

On examining the mouth of the child, I became convinced, from the inflamed and swollen condition of its gums, that the constitutional disturbance was caused by irritation produced by the advancing teeth. The child had a convulsion soon after I saw it; and as an old woman, a sort of doctress of the neighbourhood, had predicted the day before that it would die the next day, between ten and twelve o'clock, saying that mortification of its bowels had taken place, the afflicted mother supposed the infant was in the agonies of death. But the old woman seemed rather happy than otherwise, that her prediction was about to be fulfilled. Believing that lancing the gums freely down to the advancing teeth, was the only remedy that promised any relief, I took the child from the cradle, and with the consent of the mother, performed this operation. It was relieved almost instantly, and immediately, on being taken by the mother, it took the breast, and was soon lost in a quiet sleep. Its recovery from this time was uninterrupted and rapid.

The above case is similar to one related by Prof. Harris to the students of the Baltimore College of Dental Surgery, while the writer was attending lectures in that institution, during the session of 1845-6. I would ask, in conclusion, what causes the death of ten thousand children, annually, in the city of New York alone? Has not morbid dentition something to do with this fearful mortality? In cases like the foregoing, medicine may afford temporary, but will seldom give permanent relief.—*Amer. Jour. of Dent. Sci.*

#### NEW MODE OF TAKING COD-LIVER OIL.

I HAVE read Mr. Selwyn Morris's "New Mode of taking Cod-Liver Oil," and quite agree with his general principle of using a bitter infusion. I have been in the habit of recommending to my patients the use of pale or bitter ale as one of the best vehicles in which to take the oil, be it cod-liver or castor. This description of ale being intensely bitter, and tonic to boot, from the large quantity of hops used in its manufacture, serves the purpose admirably; and another advantage is, that it can be obtained more readily than a quinine mixture or an infusion of quassia; and, moreover, being a stimulant, the stomach is also beneficially excited to retain and digest the fatty oil. As an extempore vehicle, I have frequently used the concentrated infusion of gentian (of course diluted) with good effect; but when there is time to prepare an infusion, I would certainly give the preference to the quassia. NOTE.—We have received a letter recently from one of our patients who, whilst in Dublin, consulted Dr. Graves, was advised by him to take cod-liver oil, in infusion of quassia, which, no doubt, that eminent physician has found to conceal the taste of that valuable though disagreeable remedy.—*Canada Medical Journal*.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JANUARY 12, 1853.

## THE CASE OF KIRWAN.

Our readers have learned that this convict has escaped the extreme penalty of the law. How far this may have been owing to a conviction of his innocence, or to other considerations, we cannot say; but being somewhat of the same opinion as the writer of the following article, we copy it; although many of our readers must have already seen it. It is from the *Examiner*, a distinguished London newspaper:

The example of Mr. Kirwan shows the necessity for a court of criminal appeal. For the last fortnight the press has been teeming with letters disputing the justice of the conviction of this man. The writers have had the argument all their own way, for no one is disposed to undertake the ungracious task of depriving a criminal of his last chance of life. Justice has therefore had no champion in this one-sided discussion, and the end consequently is a reprieve. Now upon what consideration can this step have been taken? Lord Eglinton, who had virtually ceased to be Viceroy of Ireland, can hardly have thought himself authorised to decide on a question of life or death, or of the justice or injustice of the judgment of a judge and jury. Lord St. Germans having barely taken his place in the Viceroyalty, can hardly have had time for the investigation warranting the arrest of the sentence of the law. But supposing there had been no interruption of the business of the department, the conclusion would really not be a whit more satisfactory than it now appears. What we have seen in the press roughly represents the proceedings in Dublin Castle; where the argument against the verdict is all one-sided, justice having no advocate, and the field being in the sole possession of the appellant, untroubled with any respondent. Yet the interests of justice in such cases are the most important interests of the public, involving its protection against the most heinous of crimes. We may be told that the convicting judge is consulted; but with life and death at stake a judge has seldom the firmness to maintain his opinion forcibly, and generally gives it the faintest expression. With a Court of Appeal, justice would be allowed its protesting voice, and strained arguments for the prisoner's innocence would be met with rebutting arguments and evidences maintaining the conviction. The objection has been started that appeal would be made in all cases, and that thus there would in effect be two trials upon the charge of murder. But this is not necessary. The discretion of referring a case to the Court of Appeal might be vested in the Home Secretary or Lord Lieutenant, who, upon the same partial grounds on which he now exercises the prerogative of mercy, might relegate the inquiry to a competent legal tribunal. The Home Secretary's or Lord Lieutenant's doubts now are grounds of pardon; but with a Court of Appeal, his doubts would simply be grounds of reference to a tribunal for rehearing, in which the interests of justice would be guarded equally with the life of the prisoner, and the truth sought by a better process than a stunning repetition of *ex parte* statements and hardy surmises. As these matters are now managed, a convict who has facility in writing, and command of pen, ink, and paper, has his own fate in his hands, if he make an industrious use of his time, and ply the press actively with letters under different signatures. This is the modern benefit of clergy. Two or three letters every day, repeating the same story with confidence, impeaching the witnesses, and harping on the danger of taking the life of an innocent man, will loose any halter. The public ends by taking fright, and the thing is done. We have been much struck by the spirit discovered in some of the appeals on Kirwan's behalf. Here is a passage in one letter in the *Times*, signed "T. G.," in which the murder of the unhappy lady is discussed with such an odious flippancy and brutal levity that we might suppose it penned by the assassin himself:—"Mrs. Kirwan did die somehow or other out of the common way. She screamed before she died. Her body was bruised. It was found under peculiar circumstances. Her husband almost killed himself in seeking it, and mourned when he saw it. His grief was short and his after relief great. Of course there can be no doubt the husband killed the wife.

Yes, he killed her; but how? The doctors say in somehow that's not very clear, as by pressure, as Hercules killed Antæus—not a very likely story; rather impossible to be done now-a-days by living men, or if done, most unquestionably the pressure might squeeze out one scream, but would certainly prevent two. Or, perhaps, Mr. Kirwan sat on Mrs. Kirwan like a night-mare, and killed her so—not much more probable, unless Mr. Kirwan were as fat as Daniel Lambert or Mrs. Armitage, and Mrs. Kirwan as weak as the fasting woman at Tutbury. Or, perhaps, he ducked her head under water and kept it there, which would fully account for her vigorous screams; the faculty of screaming under water being probably peculiar to women. Or, perhaps, he strangled her by enveloping her head in a wet sheet—then it would be quite as easy to scream as if one were as free as air. Or, perhaps, Mr. Kirwan kindly took it off to give her an opportunity, and she requited his kindness by making no resistance, and leaving his person untouched and unwetted." There is the hideous zest of the Thug in these imaginings; and in most of the letters of the convict's behalf, it is remarkable that no touch of pity ever appears for the victim, who is sometimes treated almost despitely; as if it were her fault that her precious husband's life were brought in jeopardy. Let it not be supposed that we regard Kirwan's case as one of strong evidence, as it appears reported. But on the other hand, the arguments against the verdict are sophistical or purely conjectural. And, in this instance, we owe some deference to the court, that he had the opportunity of watching the bearing of the witnesses; which must be entitled to some weight, if evidence *ving voce* be of the virtue assigned to it. The case as it stands, however, is precisely one of those which would be satisfactorily disposed of by appeal if such a court had existed, as there are circumstances in dispute that might be cleared up on a new trial. It is denied, for instance, that Mrs. Kirwan's knowledge of her husband's infidelity was proved in evidence, or that it had been the subject of an angry quarrel, ending with deadly threats. An important point, too, not inquired into, is, the usual place for bathing, or places? Whether the Long Hole was the usual place? in which case it would seem extraordinary that Kirwan did not first seek his wife there. Further, a statement for the defence passed without comment, which called for observation—namely, that Kirwan was sketching till the boat arrived, though that was an hour after dark. The appointment of so late an hour for the boat, the business of the day having been one requiring light, is itself one of the many suspicious circumstances of the case.

We devote so much of our space to this extract, because it affords a remarkable contrast to the articles on the same subject published in a medical contemporary (*the Lancet*), which display an amount of zeal in the convict's behalf not very intelligible, if the object is merely the discussion of the medico-legal question. However it may be with the "discriminating" multitude commonly called "the public," we were not before aware that such demonstration of virtuous indignation and poignant sympathy was necessary to rouse the sensibilities of sober medical practitioners. It seems nevertheless that if "a sensation" is to be excited amongst "the doctors," it is to be excited by the same figures of speech which operate on the *profanum vulgus*; unless, indeed, it be that some other class in society was in contemplation when the appeals to which we allude were penned. The case, for instance, has not been soberly announced under the simple title of the prisoner's, the accused, the convict's, or the culprit's case; but the case of WILLIAM BURKE KIRWAN, in type of awful dimensions and most tragical aspect. We do not object; all we do is to remind our brethren that they require the same incentives as other people. We are also content to learn how much better they manage these things in England, notwithstanding the repeated evidences to the contrary contained in our reports of trials there: but we cannot understand how it is that evidence believed by two Judges and twelve Jurors is refuted by calling it "presumptuous swearing," except it be that the opinion of one man is better than the sentence of fourteen; neither can we see how asserting that "the

zeal of the witness did not add to the value of his testimony," proves that his testimony is to be set aside; for we know that zealous witnesses often give very valuable evidence. But if the witnesses were unworthy of belief, there is of course an end of the case: *cadet questio*, as the lawyers say. Then as to the Judge reminding the Jury that they must remain shut up all night if they could not agree to a verdict, we do not think it so conclusive of the prisoner's innocence; neither can we sympathize with the writer when he gives expressions to his agonies after the following fashion:—

Why remain the night? If the jury agreed on their verdict at half-past eight, at nine, or half-past nine, or at ten, why, in such an awful case, when a man was on trial upon the result of which his life depended, were the jury summoned and brought into court at the expiration of forty minutes, and thus disturbed in their early moments of solemn deliberation, and questioned as to whether they were likely to agree, and threatened, that as they were not likely to agree, with an intimation that they must remain during the night?

If telling a jury that unless they return a verdict they must remain during the night, be threatening them, then are many juries threatened, and many criminals nevertheless convicted. But the following argument is still more conclusive, and doubtless will go far to prove that Mrs. KIRWAN was drowned or died in an epileptic fit:—

Ah! we felt quite confident that the learned judge had gone home to dine; and, as the labour of refreshing an exhausted system occupied only about two hours and a half, probably he had left the notes of the evidence on the dinner-table in the hurry of his departure. Did the learned judge reflect on what might be the condition of the jury at eleven o'clock, they having been without refreshment up to that time, if he, at eight o'clock, was so reduced in energy, that it required two hours and a half to administer the necessary quantity of nutriment and stimulants to his frame?

When a man is exhilarated in the evening in London, he is said, in polite phrase, to have "dined;" and when he is a little more excited or unsteady, he is said to have indulged in "stimulants;" but unfortunately for the innuendo here, the learned Judge is what is vulgarly called a teetotaler, and could not have been in the state insinuated. Still, if it be necessary to set up such a theory as this, in order to convince those to whom the argument is addressed, that the prisoner is innocent, we cannot well complain. Advocates we believe are licensed to adapt their arguments and reasonings to the tastes and capacities of their hearers, and we conclude that in this case that course has been pursued; but then we cannot consider it very complimentary to the parties addressed. However, the affair is not to end here, for our zealous contemporary of the *Lancet* is not content with the gentleman's escape, but demands his "instant liberation;" declaring that "if his liberty be not at once announced," he will, incontinent, "return to the *frivolous* testimony which has been used against him!" This is an alarming intimation, and all viceroys, chief secretaries, and law officers had better look to it; especially as it is now announced, on the same high authority, that—

There exists probably no civilized community in the world, except Ireland, where a prisoner could be found guilty of a capital crime on such evidence as that brought forward in the case of William Bourke Kirwan, tried at the late Dublin Commission. From the opening statement of the crown prosecutor to the return of the verdict by the jury, the case consists of a tissue of unsupported assertion, overstrained conjecture, and absurdity.

If that does not settle the question we do not know what will, for of course no appeal can be from such immaculate authority. Ireland is, doubtless, an enigma among "civil-

ized communities," and the only place in the world from whence "unsupported assertions, overstrained conjectures, and absurdities" can emanate. We, therefore, come to the conclusion, that the effusion before us must be of Hibernian origin: for a more conspicuous "tissue of unsupported assertion, overstrained conjecture, and absurdity," it never has been our lot to encounter. It seems, however, that all discussion on this subject must now be at an end, for our contemporary, in his last number, triumphantly proclaims that "every doubt must be instantly removed by examining the further testimony." This testimony being certain affidavits made, since the trial, in support of applications for a commutation of the sentence "by, amongst others, the mother, the uncle, the cousin, and several friends of the deceased lady," to the effect, that "Mrs. KIRWAN was fully aware of her husband's connexion with Miss KENNY;" that "there could not be a more industrious, sober, or quiet husband;" that "witnesses, prepared to swear to these extenuating circumstances were not examined, either for the prosecution or the defence;" that "the deceased always spoke in the kindest manner of the conduct of her husband, and always appeared in the full and affluent enjoyment of comfort and respectability;" and also invariably stated, that "a more quiet, gentle, good-natured, or generous-hearted man never existed;" and also extolled "his tenderness, attention, and kindness to her when sick." There is also an affidavit of one ANNE MAHER, a woman servant, that "two years ago she was attracted by loud screaming up stairs, and found Mrs. KIRWAN working in a fit, and froth coming from her mouth," which fit "lasted about half an hour;" and a similar one from an artist of the name of KELLY, an assistant of KIRWAN's, who "remembers the deceased to have been attacked with two fits; one about two years ago, when KIRWAN and ANNE MAHER were present, and another in the latter end of June last." There is also a statement that the leading counsel for the defence, and three other gentlemen, "were not aware of these facts until it was too late in the trial to use them," but the words of that statement not being quoted, must be received with caution; and the more especially, because it is absolutely absurd to pretend that these gentlemen were not aware of these facts, the persons deposing to them being in court, summoned by the crown, and KIRWAN himself in the dock within a few feet of his attorney. Yet is this *ex parte* swearing "held to be sufficient to remove all doubts," while the evidence for the prosecution is pronounced to be little less than perjury. We ask pardon of our readers for dwelling at such length on this subject, but we wish to clear away all this rubbish previous to a rigorous scrutiny of a case which must hereafter be recorded as one of the *causes celebres* illustrative of forensic medicine. It is an ungracious task to write—we do not respecting it, but the character of our profession is more or less at stake in its discussion, and we cannot allow it to be trifled with. We do not presume to decide positively as to the prisoner's guilt or innocence, for the case is obviously one upon which a difference of opinion may be entertained by some; but we do presume to repudiate the arguments and sentiments to which we have been alluding, lest they should be construed into an expression of professional opinion. We may perhaps return to the subject presently.

Since the above was put in type, we find in a morning paper (*Saunders' Newsletter*), a communication made on

behalf of eleven of the twelve Jurors who tried the case, declaring, that "upon a full review of the evidence adduced at the trial, and all the reasoning brought to bear upon it since, they firmly adhere to their verdict; and also solemnly declaring that not one rational doubt has been suggested to their minds;" also, "that they hold all the circumstances of the case to have been perfectly incompatible with KIRWAN's innocence, and that he is guilty of the deliberately-planned murder of MARIA KIRWAN, his late wife." They also say that "they see strong reason to doubt that there exists any sworn testimony, which could be relied upon, that Mrs. KIRWAN ever had fits of epilepsy," notwithstanding the affidavits above alluded to; adding, that "they have been furnished with these documents but do not believe them." They also express their disbelief of the tale, that Mrs. KIRWAN's father died of epilepsy. At the same time, they also express their gratification that the convict's life has been spared, such result being to them, who found him guilty, a great boon; "though the verdict was wrung from them by irresistible and almost unresisted testimony, they could not cast from their minds the painful weight that consigned a fellow-creature to death." Moreover, they say that "no evidence was called for the defence, excepting medical testimony, which did not touch the circumstances of the case," and that they could not deliver a verdict founded on doubts they did not entertain; concluding by saying, that "this defence is due to themselves as honest, and, they believe, not mistaken men, to public opinion so industriously abused, to the ends of truth, and the sacred character of trial by jury;" admitting that in making it they pursue an unprecedented course, but that "it has been forced upon them by a repetition of malignity and falsehood from a portion of the press which in either country it is seldom led into."

### GRATUITOUS MEDICAL SERVICES.

Our readers must by this time have perceived that we are anxious to make them acquainted with the state of medical practice in the United States; and we are so, because we wish them to learn in what way it differs from that of the old country. With this view we copy the following, which prove that the same evils which prevail here are equally prevalent there, notwithstanding a much better understanding between the respectable members of the profession:—

At a meeting of the Delaware County Medical Society, a report was read upon the subject of gratuitous services to the poor, and the following resolution was adopted:—

"That the delegates to the State Society in May next be instructed to offer for the consideration of that Society, the report made by the committee upon that subject, of which the following is an abstract."

The committee report that its investigations have not extended entirely throughout the whole county, but sufficient has been shown to prove that the average loss to every physician for a single year is one hundred and thirty-two dollars for services rendered, and twelve dollars for medicines furnished, making an annual contribution to the cause of humanity of one hundred and forty-four dollars from every practising physician.

Taking, then, this estimated average of one hundred and thirty-two dollars for services rendered, and twelve dollars in money for medicines, actually extracted from the pockets of every physician, your committee believes that it has before it a subject so manifestly unjust, and an evil so glaring, that it becomes a legitimate object for remedy through the united efforts of medical association.

Physicians, as a class of men, owe no more to society, and are under no higher obligations to the cause of humanity, than any other. We, therefore, consider that this forced contribution to society at large, from those who are com-

pelled to pay all other taxes levied for public benefit, is an unjust extortion to which they have no right to submit. Our investigations and experience both sustain us in asserting that deeds of benevolence and charity to the sick and suffering, although matters of daily occurrence among physicians, make no part of the losses which the committee has been called upon to exhibit.

Therefore resolved—"That the President of the State Society be authorized to appoint a committee of five to report upon the subject of gratuitous services, as set forth by the Delaware County Medical Society to this Society."

The Committee of the Philadelphia County Medical Society appointed to take into consideration the communication from the Delaware County Medical Society, in relation to gratuitous medical services to the poor, respectfully report:—

The Delaware County Society desire the coöperation of this Society, in devising some means whereby the services of physicians to the poor, in their respective neighbourhoods, which are, from the inability to pay, now gratuitously tendered, shall be rewarded. The Society correctly remark, that physicians, as a class, pay their due proportion for the maintenance of the poor, and for other purposes connected with the support of the commonwealth; and yet they are expected to give their time and professional services to those who are unable to pay, to an extent far beyond what is required of any other class of the community. It is not apparent from the communication of the Delaware County Society, submitted to us, how far they deem it proper for physicians to go, in giving gratuitous services to the poor—what class is to be favoured, and what class to be exempted—whether charitable institutions shall, indiscriminately, be charged for such services; and if not, what class of them shall be attended without charge? These are questions which have long occupied the minds of medical men, and it may not be amiss briefly to consider them in connexion with the subject now submitted to us.

It places our profession in the exalted position of a liberal and benevolent calling, and assign to its members public duties and responsibilities from which they cannot honourably shrink. It is true, that properly to fulfil these obligations requires no small degree of self-sacrifice; and where their gratuitous services are not appreciated by the public, or are met even by indifference and neglect, these services become doubly onerous. Still they are a part of the physician's duty, as the member of an educated and beneficent profession; and upon his faithful performance of them depend his own peace of mind, and the preservation of the character of the body to which he has voluntarily attached himself.

The committee would therefore be averse to any action which should in anywise contravene the established usages of the profession, as laid down in our code of ethics; or which should detract from that high character, for disinterested benevolence toward the sick and destitute, which has for ages characterized the medical calling. We can refer with honest pride to the past history of medicine, as furnishing a more distinguished line of public benefactors than are to be found in any other calling. How many physicians, without the expectation of pecuniary reward, or the hope of future fame, have calmly and resolutely braved the horrors of pestilence, and have even fallen victims to its ravages, while attending with impartial fidelity upon the rich and the poor, who, in the general panic, have been deserted by kindred and friends! How often have the duties of the sympathizing friend, the attentive nurse, and the skilful physician been combined in the same person, when danger threatened, and the last extremity seemed near at hand. What higher character can we contemplate in the scenes of actual life, than the wise and good physician, the profound and learned medical philosopher, ministering with his own hands to the poverty-stricken victim of disease; cheerfully encountering the dangers, privations, and toils, incident to his position, with the prominent desire of benefiting his fellow man. The ignorant pretender, or the presumptuous charlatan, who advertises his services and boasts of his cures, manifests in his every act the mercenary spirit by which he is actuated; and however he may succeed in amassing wealth, in rearing splendid mansions, and in surrounding himself with the elegancies and luxuries of life, he can never acquire that elevated position in the eyes of the community, which is occupied by the truly scientific and honest physician. This is, indeed, one of the grand distinctions between the regular practitioner and the charlatan. The former scorns to boast and make extravagant promises for the purpose of extracting money from the pockets of the people, while the latter openly avows

that this is his sole business. Having premised this much in regard to the general character of our profession as a liberal and humane art, your committee would remark, that while the physician feels and acknowledges that he owes duties to the public from which he cannot honourably shrink, he, at the same time, insists that the public owe to him certain obligations which they are equally bound to cancel.

In the language of the code of ethics, "justice requires that some limits should be placed to the performance of these good offices." These limits are, to a certain extent, defined by general custom, though not perhaps with sufficient clearness to become established rules. All admit that the industrious and honest poor, who are struggling to maintain a respectable appearance, or to keep themselves above public or private bounty, and yet whose means are barely sufficient for their support, even when health and opportunity are at their command, should be favoured by the physician: such are widows with families of children; single women who live by the precarious and badly paid occupations of the needle; housemaids who assist in supporting helpless or needy relatives; sickly and broken-down persons, who have once been in more fortunate circumstances, and are too old and feeble to labour; together with many others of similar classes.

Your committee conceive that any action on the part of the county societies which should secure such compensation in those districts of the state where it is withheld would be both reasonable and just; and if the salaries attached to such appointments are meagre and unsatisfactory, that the profession should unite in demanding an increase of them. That there are a class of persons in all communities whose means will not enable them to make the customary compensation to physicians, and yet who are above public charity, we are aware; but we can see no way of dealing with these other than that already pointed out in the code of ethics. There is also a class of public institutions in all large and populous cities, to which the services of physicians and surgeons have always been gratuitously tendered. Such are hospitals founded by private charity and supported by funds bequeathed from time to time by benevolent individuals. Such institutions are generally admirable schools of knowledge and experience, and the medical men attached to them obtain thereby a larger amount of public confidence than they would otherwise enjoy, and by this means their private interests are advanced to an extent equivalent to the time and labour bestowed.

#### LOUTH MEDICAL ASSOCIATION.

THE quarterly meeting of this Association was held at the County of Louth Infirmary, on Monday the 3rd of January. Arrangements were made for the purchase and interchange of periodicals among the members, and other business was transacted. The next meeting will take place in April, when it is hoped such arrangements may be made as will ensure the reading of papers on interesting medical cases at the future meetings.

TO CORRESPONDENTS.—We must still postpone some matters which we are anxious to handle, but they require more dissection than we can reach upon this week. Why do not some of our correspondents help us more with a little finished work rather than furnish us with the raw material only.

#### CORRESPONDENCE.

(Extract of a Letter from a Correspondent.)

INDEPENDENT of the valuable matter your journal contains, the Dispensary Medical Officers must feel grateful to you for your able advocacy against the injustice done them in some districts in fixing their salaries on such a miserably low scale. In this union (Macroom), districts are very large and salaries £50 per year. You can easily imagine, after the support of a horse and servant-man (indispensable appliances in a rural district), what this paltry remuneration leaves for the discharge of laborious and anxious duties. Heretofore my salary was somewhat respectable, with a third of the duty to perform. There were three dispensaries in this district attended by three medical officers at a cost to the county of £300 a year. They are now amalgamated into one—the Clonmoyle Dispensary, at a salary of £50 per year. Is this reasonable? Is it just?

#### MEDICAL METAMORPHOSIS.

The Governors of the Cork Foundling Hospital have, with the consent of the Poor-law Commissioners, on the score of economy, dismissed their physician, who filled the post, with credit to himself and advantage to the institution, for a period of twenty-seven years. In lieu of his salary (£60 per annum), they have given him a sum of £400 as compensation, but at the same time they have appointed an apothecary to take charge of the children (about 160) remaining in the establishment, at a salary of fifty guineas per annum. The institution has abundant means for the payment of a qualified medical man.

Can any one enlighten us regarding this affair, for we cannot well comprehend the meaning of it? These children must have some legal title to medical attendance, which no authority can set aside or trifle with.

#### THE REVERSED AND DOUBLE-ACTIONED PATENT TRUSS.

Invented by FRANCIS L'ESTRANGE, Esq., F.R.C.S.I.

WILLIAM DUFF, of 37, Molesworth-street, Dublin, calls the attention of the Medical Profession and the Public to this Truss. He can state with confidence it is the only instrument constructed on Scientific Principles, having for its object the Radical Cure of Rupture. It acts not merely as a palliative, but will produce a radical cure, as is attested by numerous certificates.

W. D. is the only Manufacturer of the Instrument. The trade and public institutions will be liberally dealt with.

#### TO SURGEONS, DISPENSING CHEMISTS, ETC.

SULPHATE OF QUININE, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, capped, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.

October 23, 1852.

Just published, in foolscap 8vo, cloth, price 5s..

### SIX LECTURES INTRODUCTORY TO THE STUDY OF CLINICAL MEDICINE:

Comprising the mode of Examining Patients, Percussion, Auscultation, the Use of the Microscope, and the Diagnosis of Skin Diseases.

By JOHN HUGHES BENNETT, M.D. F.R.S.E.,  
Professor of the Institutes of Medicine in the University of Edinburgh.

Sutherland and Knox, Edinburgh: Simpkin, Marshall, and Co., London.

### NEWSPAPER FOR THE FARMING AND GARDENING INTEREST.

January 1, will be published, price Sixpence, free by post, each volume complete in itself,

*Enlarged to twenty-four folio pages,*

The First Number for 1853, of the

### GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE;

A Weekly Record of Rural Economy and General News.

*The Horticultural Part Edited by Professor Lindley.*

The Farming Part (under the Editorship of a Practical Farmer) treats of—

The Practice of Agriculture,  
Agricultural Science,  
Animal and Vegetable Physiology,

Improvements in Implements,  
described by Woodcuts whenever requisite,

Better modes of Husbandry,  
Results of Experimental Farming,

Growth and Rotation of Crops,

Management of Stock,  
Veterinary Science,  
Drainage,  
Irrigation,  
Forestry,  
Road-making,  
Farm-buildings,  
Labourers,  
Treatment of Poultry,  
Agricultural Publications.

In short, whatever affects the beneficial employment of Capital in Land.

Reports are regularly given of the English, Scotch, and Irish Agricultural Societies and Farmers' Clubs—London Market Prices of Corn, Hay, Cattle, Seeds, Hops, Potatoes, Wool, Coal, Timber, Bark, &c., and the Weekly Averages.

As regards the Gardening Part (under the Editorship of Dr. Lindley), the principle is to make it a weekly record of everything that bears upon Horticulture, Floriculture, Arboriculture, or Garden Botany, and such Natural History as has a relation to Gardening, with Notices and Criticisms of all works on such subjects. Connected with this part are

*Weekly Calendars of Gardening Operations,*

Given in detail, and adapted to the objects of persons in every station of life; so that the cottager with a few rods of ground before his door, the amateur who has only a greenhouse, and the manager of extensive gardens, are alike informed of the routine of operations which the varying seasons render necessary. It moreover contains Reports of Horticultural Exhibitions and Proceedings—Notices of Novelties and Improvements—in fact, everything that can tend to advance the profession, benefit the condition of the workman, or conduce to the pleasure of his employer; Woodcuts are given whenever the matter treated of requires that mode of illustration.

Replies to Questions connected with the object of the Paper are also furnished weekly.

Lastly, that description of Domestic and Political News is introduced which is usually found in a Weekly Newspaper. It is unnecessary to dwell on this head further than to say, that the Proprietors do not range themselves under the banners of any Party; their earnest endeavours are to make the *Gardeners' Chronicle and Agricultural Gazette* a full and comprehensive record of facts only—a Newspaper in the true sense of the word—leaving the reader to form his own opinions: their object being the elucidation of the Laws of Nature, not of Man. The reader is thus furnished, in addition to the peculiar features of the Journal, with such information concerning the events of the day, as supersedes the necessity of his providing himself with any other weekly paper.

A Prospectus, with List of Contributors, may be had on application, or by letter, at the Office, 5, Upper Wellington-street, Covent Garden, London.

Parties intending to commence with the New Volume had better give their orders at once to any News-vender.

### BRAITHWAITE'S RETROSPECT OF MEDICINE.

Just published, price 6s., the 26th Volume of this Work, giving a careful Analysis of the most Practical Papers, Lectures, and Transactions of Societies, published in all the Medical Journals within the last Six Months. Appended to which is an Alphabetical List of Diseases; with the most recent Suggestions of Treatment.

Edited by W. BRAITHWAITE,  
Lecturer on Obstetric Medicine in the Leeds School of Medicine, &c.

N.B.—A limited number of the above Work, volumes I to 25, has been made up. Price reduced to £4, in cloth (for complete sets only). Published at £7 1s. 6d.

London: Simpkin, Marshall, and Co.  
Edinburgh: Oliver and Boyd. Dublin: Hodges and Smith.

### THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY,)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System.

Under the direction of Dr. JACOB,  
Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

### TO THE MEDICAL PROFESSION AND THE PUBLIC.

GEORGE OLDHAM AND CO.,

### APOTHECARIES AND CHEMISTS,

in availing themselves of the present opportunity to return their grateful acknowledgments to their Friends for the support which they have hitherto received, and which they will regard as a fresh motive for exertion, beg leave to announce that they have taken the

ROYAL MEDICAL HALL, 64, DAME-STREET,  
(Late Bewley, Owen, and Co.'s,)

which they will henceforward conduct in connexion with their MEDICAL HALL, 107, GRAFTON-STREET.

In notifying the above change in the management of the Royal Medical Hall, G. O. and Co. can assure the present Friends of that establishment, that the same scrupulous attention and care has been paid to the selection and preparation of their Medicines and other articles, which has gained them such extensive support in their Medical Hall, 107, Grafton-street; and they hope their arrangements to ensure accuracy, neatness, and despatch, combined with moderation of charges, will merit the approbation of those who may entrust them with their commands.

The Royal Shaving Cream, Essence of Ginger, Matico, Tooth Powder, Essence of Rhubarb, Ginger, and Chamomile; and other preparations heretofore made and sold at the Royal Medical Hall, can now be had at either Establishment.

107, GRAFTON-STREET,

AND

64, DAME-STREET, DUBLIN.

### CURSORY OBSERVATIONS ON PERICARDITIS: CHIEFLY ON THE DIAGNOSIS.

By HENRY KENNEDY, A.B., M.B., M.R.I.A.

THE association of ideas is a curious subject for thought, and it is owing to it that the following paper has been brought forward. A remark made by Professor Geoghegan on this night four weeks, when detailing a case of foreign body in the trachea, brought to my mind some observations which I had made on another and very different subject; and which on farther consideration, I have thought might be worthy the notice of the Society. The subject I allude to is pericarditis—an affection which, whether we consider its frequency, or its general severity, its proximate or its remote effects, must be allowed to be one of much importance.

It is, however, anything but my intention to enter into a detail of the subject. This would far exceed my present limits. I would merely make a few remarks—in the strictest sense of the term cursory—on what is now called the clinical history of the disease; and chiefly in reference to the diagnosis.

For many years past it has been known that the closest connexion subsisted between pericarditis and acute rheumatism; and of late years the valuable aid of statistics has been brought to bear on this point, and shown us that in two-thirds of the cases of acute rheumatism, there is some one or other form of affection of the heart present. We have also learned that pericarditis frequently follows in the wake of Bright's disease, as we know indeed that all serious inflammations are common attendants on that affection. The two points alluded to have been put in the strongest light by Taylor, in his elaborate paper, or rather treatise, as I should call it, while speaking of the causes of pericarditis. There still, however, remains a third general cause for the disease, which I have not seen noticed, as it appears to me to deserve; if indeed at all. I allude to the stru-

mous diathesis, which I have now seen so often in connexion with pericarditis, that there remains no doubt on my own mind of the frequent union of the two; in fact, just as we have strumous peritonitis, pleuritis, and strumous pneumonia, so do we meet an affection of the pericardium which is neither more nor less than strumous pericarditis; and the proof of this appears to me unequivocal. For besides all the usual signs of this constitution, including the age, skin, colour of the hair, &c., I have now seen several examples where tubercles were developed in lymph poured out in the pericardium; precisely analogous to what is seen on the pleura or peritoneum. I have also seen cases of pericarditis complicated with miliary tubercles in the lungs. This point, for very obvious reasons, it appears to me of considerable consequence to be aware of. If it were on no other question than that of treatment, a knowledge of it must modify it most materially. It appears strange that in London, where so much has been done by Latham, Taylor, Walshe, and others, it has not attracted any notice that I can make out. Latham, indeed, in his able and beautifully written work, speaks in very decided terms of meeting pericarditis only in connexion with the rheumatic diathesis; and to this Taylor has added the frequency of the affection in junction with Bright's disease. It is just possible that the complication I allude to may be more frequent in Dublin than London. At any rate, of its existence here there can be no doubt; and for the reasons which have been given.

It may be mentioned, in noticing this part of my subject, that I have seen pericarditis occur in the progress of fever; in three cases of scarlatina; in erysipelas—an important point, and to which Mr. Adams directed attention some twenty years since, in his valuable paper published in the "Dublin Hospital Reports,"—in cases of diffuse inflammation—that is, I have seen pure pus poured into the pericardium in such cases. I have also seen pericarditis occur in infancy and childhood, and like others have known it precede the affection of the joints for some days. Lastly, several examples have come under my notice where the disease existed *per se*, and where I was unable to detect

anything of the rheumatic diathesis. In most of these there was evidence of the strumous constitution, but not in all. Two cases of the disease where the patients were close to 60, have also come under my notice: in fact, though it must be admitted that by much the greater number of cases of pericarditis occur in connexion with rheumatism, still it is by no means confined to that state of constitution which gives rise to this disease.

On the diagnosis of this affection, I need scarcely say that it is owing to two gentlemen of our own city, Drs. Stokes and Mayne, that we are indebted for the great improvement which has taken place; and this chiefly in reference to the important sign of *frottement*—a sign which even the great Laennec himself could not make out. I have had opportunities of confirming the observations of the gentlemen alluded to, and believe them to be correct. In addition, I would beg leave to submit the following remarks on this physical sign.

It must have occurred to many present, as it has done to myself, to meet with instances where it was impossible, in the first instance at least, to arrive at a positive diagnosis. Most, if not all the general signs of pericarditis, were present; and yet the cases wanted that physical sign, the *frottement*, without which, I believe, it would be impossible to pronounce the disease present. Under these circumstances, and whilst still in doubt, it struck me that possibly the following plan might be useful; I mean exerting pressure over the region of the heart.\* It will be recollected that the great majority of cases of pericarditis occur in young persons. Now, in such I have found that a gentle and slowly increased pressure, on either side of the bell of the stethoscope, will produce a *frottement* much earlier than it would otherwise be heard. This is best done by a second party, though it is possible to do it for one's-self. When formed, so to speak (for it is not always to be accomplished), it has been at the base of the heart I have first heard it. That it is a rational mode of proceeding, I think I may assert; and the proof appears to me to be that, if in any case *frottement* be present, without any pressure, it is possible to make it louder by then using this means. The objection to the measure lies in the fact, that some patients cannot bear the pressure, the general distress is so great; still, in doubtful cases (and it is of such I am now speaking), momentary pain must be submitted to, for the important purpose of ascertaining the existence or non-existence of inflammation of the pericardium. A few hours, in a disease of this sort, makes a material difference, as every one knows, in the successful treatment of the case.

As a modification of this plan, which, you will observe, is merely bringing the layers of the pericardium closer to each other for a moment, I had long acted on the idea, that altering the position of the patient effected the same end; and such is the fact, at least in this degree, that a *frottement* which is doubtful while the patient is horizontal, becomes much more distinct when he sits up. This I believe to be partly due to the sudden exertion increasing the action of the heart, and at the same time the opposing surfaces of the pericardium being brought nearer to each other. This mode of proceeding, I confess till very lately, I thought was new; but on looking over the elaborate work by Dr. Walshe of London, I find that he specially alludes to this point, and in reference to the diagnosis of pericarditis. At any rate, it is satisfactory to know that my own observations have been confirmed by another and abler hand.

Either of the ways just spoken of are, I believe, of much

value in doubtful cases, and not to be neglected. In some instances at least, they will clear up a difficulty which would otherwise remain.

Connected with the first appearance of *frottement*, I have observed some points which, as far as I know, have not been described, and yet are of importance to be aware of. I allude to the fact that in some cases the rubbing sound is at first intermitting, so to speak—that is, several beats of the heart will occur without causing it, and then it will be heard. In this way nine or ten beats may occur, and but one of these cause the sound we are looking for. This point I have noticed at the very earliest period that *frottement* could be expected to occur; and it is particularly worthy of notice that the same thing is to be observed either when the disease is progressing to the stage of serous effusion, or when it is on the decline. The explanation I would offer of this intermitting *frottement* is, that it is due to the unequal action of the heart—a state which every one who has seen the disease must have been struck with, and that so the *frottement* occurs occasionally, whether there be but a small quantity of lymph poured out, or whether there be a considerable amount of serous effusion present.

The second point I would notice is the fact, that the *frottement* may be single. In place of the double friction sound, but one is heard. For a long time I was in doubt on this point; but in every case which has lately come under my notice, I have taken every care to be accurate, and I think I may now announce it as a fact.

I do not mean to say that a single friction sound will, in any case, be heard to go on as continuously as the ordinary *frottement*, which is known to be double. But I do state that in some cases a single rub takes precedence of the double one; before, in fact, the double one is formed; and again when the double *frottement* is on the decline, it is not at all uncommon to hear, at irregular intervals, a single rub. The irregularity of this single *frottement*—that is, its occurrence at only certain beats of the heart, will always serve to distinguish it from another sound with which it would otherwise be possible to confound it. I mean a *bruit de souffle*. This latter sound has always, as far as I have observed, been constant; at least for the time being.

For so far I have been speaking of the presence of *frottement*, and the means by which it may be rendered apparent, in certain cases of pericarditis where doubt may exist. I would now, however, allude for a moment to those cases of the disease where this sign is not present, from first to last. Others have made allusion to some of these cases; as for instance where pure pus is effused into the pericardium. The cases, too, where the lymph is not adherent to the serous surface, would also appear to afford instances where *frottement* would not be present. Such as some cases of what may be called sanguineous pericarditis which most present may have seen; and also that form of the disease which occasionally complicates erysipelas: and in which, as far as I have seen, the amount of serum is much greater than natural, with a soft lymph floating about in it; in fact, it might be called serous pericarditis. But on these two forms I do not speak from experience, though I believe that in neither is a state of parts present which would afford a *frottement*. I have alluded to this part of the subject here, however, because I have seen cases where, looking to the state of the parts, there was every reason to suppose that a *frottement* should have existed, and yet it did not. In the cases I speak of (two in number), lymph existed over the serous surface, in the form of a layer; and in addition a quantity poured out, free as it were, and of an unusual degree of firmness. Probably some detail of one of these cases (which were very similar) would give a better idea of what I am speaking of.

Case.—A woman, aged 57, was admitted into hospital for chronic bronchitis and emphysema. Her chest was what the French call *bombais*; her pulse 80; in fact, she presented no peculiarity. On the third night of her admission, having occasion to rise, she was in a moment seized with a violent rigor, soon followed by distressing vomiting, and when visited she was found in a state of the utmost distress.

\* Since writing the above, my friend Dr. Bellingham, has directed my attention to a paper by Dr. Sibson (published in 1844), and in which this point is noticed. The title of this very able paper is not such as would lead any one to expect that such a subject would be discussed in it; and hence I had overlooked it.

She referred her sufferings to the chest, and described as if some great pressure were impeding her breathing. Dyspnoea, but of a very aggravated character, was in truth her complaint; her countenance, from having been quiet, was now anxious to an extreme degree; her nostrils were acting powerfully, and she was most restless, as regards her arms; but did not toss about in the bed. The symptom, however, which particularly took attention was the pulse. From having been 80 and regular, it had now risen to a height, which, joined to its irregularity, made it utterly impossible to count it. It was at a guess 160, at the same time that every beat was, or appeared to be, different from the preceding; while every four or five beats was followed by a distinct intermission. If the pulse were hard to count at the wrist, it was much more so when the stethoscope was applied over the heart. Here everything was in a state of confusion, so to speak; nor could I describe it otherwise than as conveying to the ear the idea of trembling. The patient lived about sixty hours in the state described; and without any appreciable change except that the general distress became still more urgent. During this period she was examined several times, but still no frottement could be detected. The disease indeed had been guessed to be pericarditis; but it was more because there was nothing else to account for the symptoms; for the stethoscope showed that there was not enough wrong in the lungs to give rise to such a serious state of the system. On making a post-mortem examination lymph was found coating the serous membrane of the heart. There was also lymph lying in masses the size of a nut, in the sac itself. This lymph was unusually firm, and what was curious was there was not more than half an ounce of liquid effusion; if even so much. The explanation I would venture to offer of this case is, that the extraordinary irregularity of the heart's action prevented that to-and-fro motion of the organ on which frottement seems in part to depend. Possibly the very small amount of liquid effusion may also have contributed to this. Irregular action of the heart is not by any means uncommon at the onset of pericarditis—a point which Dr. Graves has long since noticed. This, however, frequently passes away, and the beat of the heart, though it may remain unequal, often becomes otherwise regular. Whether an effusion of lymph alone, or nearly so, is a cause of irregular action, I cannot say. But from the result of the case just given, and another very similar, I rather think it is the cause why no frottement was heard in either; in fact, the rubbing sound requires a specific state of parts to give rise to it independent of the effusion of lymph; and this effusion alone does not appear to be one of these. This particular point is worthy of further investigation.

The last point, in connexion with the physical signs which I would notice is, that in many cases of pericarditis the respiration becomes, in a very marked degree, puerile. Dr. Walshe alludes to this point: but he comes to the conclusion that it is not an attendant on acute pericarditis. This, I must say, does not agree with my experience. I have seen a number of cases where it existed in a marked degree; and what is of more consequence it may be traced sometimes from the left to the right lung; though in other cases it shows itself in both at the same time. In the case which has been given above it existed to as great a degree in both lungs, and from the very first, as their state was capable of allowing. When this puerile respiration begins in the left, which, by the way, it is sure to do, and then passes to the right lung, it has appeared to me a sure sign of the increase of the disease, and *vice versa*; its decline, after it had once existed, shows very clearly the retrocession of the disease. On the whole, when this form of respiration is present (for it is not always so), and when it is recollected the great facility with which it can be caught by the ear, it affords most valuable assistance, both to diagnosis and prognosis. I have found it, in fact, a direct measure, in such cases, of the intensity of the pericarditis present, and I believe it to be a sign which we should always look for.

Of the existence of slow pulse in some cases of acute

pericarditis, I need not speak. It has been noticed specially by Dr. Graves, and I have been able to confirm it in three instances. In the last, which occurred about a fortnight since in Cork-street Hospital, under the care of Dr. G. Kennedy, the pulse, even at the height of the attack, never exceeded 86; and this though the patient was a young man of only 18. In this particular instance, I had an excellent opportunity of testing the several points, which I have already spoken of, in reference to the frottement.

On the treatment of pericarditis I have very little to say. I would just observe, however, that there seems to me to be a great risk if we were to follow out what some have lately recommended. Thus, I find Dr. Todd of London—and his name has now deservedly great weight—speaking of the application of blisters alone, together with some constitutional treatment, and this not mercurial, as being the means best suited to meet the disease. That is, in other words, no bleeding of any kind is used. This may be the best practice in London, even though there be many there who do not follow it; as, for instance, Latham, Walshe, and others. But it certainly does not appear to me to be the treatment best suited to the cases to be seen in this city.\* That general bleeding, in many of these, and at the onset of the disease, is most useful, I have no doubt of. Neither, as bearing on this point, must the fact be overlooked, that it is not uncommon to see smart epistaxis occur at the beginning of the attack. I know, too, that others have seen this as well as myself, and I cannot but look upon it as a most significant sign of the path we should follow.

Whatever doubt, however, may be raised as to one or two general bleedings, there can be none, I think, as to local depletion. The good results are so marked as to be unequivocal; especially the abstraction of blood by cupping, when this last means can be borne, for this is not always the case. When the case is of that kind which I have ventured to call strumous pericarditis, general bleeding appears to me out of the question; but, on the other hand, I know that in such cases blood may be taken locally, and, by using ordinary discretion, with great advantage. There is a stage of the disease, however, which appears to me to require more attention than it has hitherto received. I mean the time when we should cease to use an antiphlogistic treatment, and adopt a modified stimulant one. Any one who has had to deal with this disease, will have met cases where all the signs of inflammatory action continue in spite of all the antiphlogistic treatment which has been adopted. I have repeatedly seen such cases. Now, in such, I am sure that a perseverance in the original line of treatment will only make matters worse, and the sooner we change our hand the better; and we may, in this view, commence to give stimulants, even at the time when we may be compelled to draw blood locally. I am not speaking of this as conjecture, but as matter of experience, and as being a point of practice which may prove very perplexing.

Though speaking now only of the question of abstracting blood in cases of acute pericarditis, I do not mean for a moment that we should omit the use of other remedies, as calomel and opium, blisters, diuretics, &c. These are all of the most essential service, and I believe, if properly

\* I find what is stated above more than confirmed by a lecture given by Dr. Todd, and published in the *Medical Times and Gazette* of December 18, 1852. The lecture is on a case of acute rheumatism, complicated with pericarditis, pleuritis, and pneumonia. The patient's age was 20; he was in good condition, and it was a first attack. The treatment first directed was the employment of hippo, opium, and nitre internally, with the external use of turpentine and blisters. Subsequently, calomel and opium was given, and so as to cause salivation; and at a still more advanced stage, wine. Had a case like this survived, and subjected to this treatment, it would, it appears to me, have been a miracle, not a recovery; and I must confess myself completely at a loss to understand the rationale of the treatment pursued in such an extreme and urgent case.

used, are capable of causing a complete cure of the disease. I have seen this question discussed—that is, whether a *bona fide* cure can be effected in pericarditis once lymph has been effused. I do not mean the cure brought about by adhesion; for though the French make light of this state of parts, and speak as if it were a complete cure, I cannot bring myself to think so of it. I have never yet seen an example of adhesion of the serous layer of the pericardium where more or less organic affection of the heart did not exist. But I do speak of the restoration of the sac to the state in which it was before the attack. Dr. Graves thinks that this does occur, and I believe it does myself; though, on the other hand, I admit it is very rare. I have notes of one case where there is every reason to suppose such a cure was effected. It was that of a gentleman of 20 years of age, who was attacked with rheumatism of the most acute kind. In the progress of this, he was seized with pleuritis and pericarditis, putting his life into imminent danger. Under the sanction of Dr. Stokes and the late Mr. Colles, he was most actively treated, being bled from the arm three times, and locally four times. The frottement which existed in this case was succeeded by an exceedingly well-marked bruit, taking the place of the second sound of the heart. This, after a time, gradually became weaker, and finally ceased completely; nor could I reproduce it by making the patient take active exercise. Ten years have now elapsed since this case occurred; nor is there now the slightest reason to suppose the heart, and parts about it, otherwise than healthy.

Before concluding these remarks, which it will be recollected are strictly cursory, I beg leave to throw into propositions the chief points which appear to me worthy the notice of the Society.

1. That in addition to the close connexion which subsists between acute rheumatism, Bright's disease, and acute pericarditis, it is not at all uncommon to meet the disease under a form that may well be called strumous pericarditis.
2. That by means of pressure, and occasionally by altering the position of the patient, a frottement may be produced some hours before it would otherwise become audible. (Noticed by Sibson.)
3. That at an early stage of pericarditis, a single intermitting frottement is not uncommon.
4. That when the disease is on the decline, or when serous effusion is taking place, the same phenomenon may be observed.
5. That solid lymph may coat the pericardium, and yet no frottement be formed.
6. That great irregularity of the heart's action will possibly account for this.
7. That puerile respiration is often a symptom of pericarditis, and may then be a sign of much importance, both as to diagnosis and prognosis, and may occasionally be traced passing from the left to the right lung.
8. That in some cases of acute rheumatism and pericarditis, Nature relieves herself by epistaxis.
9. That after a certain period of the disease, even though the signs of inflammatory action be still present, we may change our line of treatment with the greatest advantage.
10. That there are the strongest grounds for supposing that a perfect cure of pericarditis, after lymph has been effused, may be effected.

**DEATH FROM COLCHICUM.**—John Clements, Captain of the Government hoy *Mary*, got from the "lob-lolly boy" (the boy that attends the surgery) of H.M.S. *Rosamond*, a bottle of medicine having on the label "tinc. sem. colchic.," which had been prepared to be administered for the gout or rheumatism. The captain, understanding that it contained some alcohol, and feeling rather chilly, took a wineglassful, which was equal to two ounces. He was soon afterwards seized with retchings and pains, when Dr. Gunn, of the Deptford Victualling Yard, attended and prescribed for the unfortunate man, but ineffectually, as he died soon afterwards, from, as it appeared at the inquest, the fatal draught. The jury found great fault with the assistant-surgeon of the *Rosamond* for having left so powerful a potion in the hands of an ignorant boy.

## POPLITEAL ANEURISM CURED BY COMPRESSION.

(Under the care of Mr. Cock.)

**WILLIAM G—**, aged 57, and a carpenter by trade, was admitted, Nov. 15, 1852, into Luke ward, Guy's Hospital, under the care of Mr. Cock. The patient has exerted himself as much as is usual in his calling, but never imposed more fatigue on the right leg than the left. He is of high stature, robust, has always enjoyed good health, and been particularly temperate in his habits. He is of a quiet, contented disposition, and possesses an average amount of intelligence. The man is married, has many children, and does not remember having injured either leg in the slightest degree; nor did the affection ever exist in the family. Three months before admission, the patient's right thigh and leg pained him much for a few days, and he was under the impression that the pain was seated in the bone. This attack did not last long, and the patient soon thought no more of it, until one month afterwards, when he noticed a little lump in the popliteal space, of the size of a plum. Pulsations were then distinct, but much fainter than they subsequently became. No actual pain was experienced, but the tumour for the next two months became gradually larger, though the patient was never prevented from walking as usual, going even great distances without inconvenience.

On admission, the patient's state was the following:—There is a strongly pulsating tumour, partly in the right popliteal space, and partly lower down towards the gastrocnemius muscle. The swelling begins above, in the popliteal space, opposite to the upper border of the patella, and ends below, on a level with the tubercle of the tibia. The tumour is round, and about the size of a turkey's egg; it pulsates strongly, and presents, on auscultation, a strong bruit. The chest, on careful exploration, does not yield any evidence of thoracic aneurism. The tumour feels yielding and elastic, and the hand placed upon it receives a sensation as if the vessel were dilated more towards the inner than the outer side.

Mr. Cock, after considering all the symptoms of the case, and giving due regard to the constitution, health, temper, &c., of the patient, resolved to give compression a fair trial, and used a clamp lately modified by Mr. Bigg, to which the latter has given the name of "Bigg's aneurismal compressor." The instrument may be described as follows:—A semicircle of steel, with anterior and posterior moveable arms, the anterior containing the screw and pad to rest on the artery, the posterior holding the hinged cushion or splint, on which the limb is placed. When the instrument is applied, the pad is screwed down so as to gently compress the artery. The centre screw is then turned to direct the pad inwards, and fix the artery between it and the bone. The lower screw placed beneath the cushion raises the outer edge of the splint, and prevents the instrument moving in the slightest degree. The advantage of this instrument seemed to us to consist principally in giving the pad a direction inwards towards the bone, and in completely securing the limb by a good broad splint, which may, by a screw placed beneath it, be brought in closer contact with the thigh.

Mr. Cock expressed himself greatly pleased with the manner in which this clamp acted all through the case.

The compression was begun Nov. 24th, and regularly continued to Dec. the 10th, making just sixteen days. The pulsations ceased five days before the apparatus was completely left off; but it was thought advisable to continue the pressure, so as to ensure the due establishment of the collateral circulation. The tumour was on the day of the patient's discharge (Dec. 22, 1852, thirty seven days after admission) just half its original bulk, and presenting a great degree of hardness. The pressure was kept up with great regularity and patience during the whole of the above mentioned period; the weight at the groin being substituted for the clamp when the latter was getting too irksome. The patient slept very little for a whole week, as he was anxious to keep up the pressure in the most exact manner; and he was fully rewarded for his close adherence to Mr.

Cock's directions, by the speedy solidification of the sac and obliteration of the artery.

When the apparatus had been completely removed, the leg was tightly and evenly secured by a roller; and when the patient first attempted to walk he felt the leg rather weak, but all pain in the limb had quite disappeared. He finally left the hospital Dec. 22, 1852, with the tumour quite solid, and the complete obliteration of the artery. This is certainly a most satisfactory result of compression in the treatment of aneurism, and likely to make a lasting impression on all those surgeons who saw the case.—*Lancet*.

We are glad of it, if for nothing else for the effect it may have in shaking the confidence of London Surgeons in their old traditional surgery, and encouraging them to cast off the trammels of domestic authority.

## ON THE INTERNAL ADMINISTRATION OF CHLOROFORM IN DELIRIUM TREMENS.

By GEORGE E. FENWICK, M.D.,

Lecturer on Materia Medica, St. Lawrence School of Medicine, Physician to the Montreal Dispensary.

J. S., aged about 40, labouring under an attack of delirium tremens, brought on by suddenly stopping all stimulants after having led an irregular life for months, came under my care on the 16th September, 1852. *Present symptoms*:—Great anxiety expressed in the countenance, fear of impending danger, frequent sighing, general tremor, delirium when left alone, which was of the quiet muttering kind, as if holding conversation with some imaginary person, pulse 110, weak, tongue covered with a whitish fur, bowels had been opened slightly that morning, appetite capricious, had not slept since the Saturday previous. It was nine o'clock at night when I first saw my patient; I ordered a full opiate, and as he had formerly been in the habit of chewing opium, I prescribed it in six-grain doses, to be repeated every second hour until he slept; two doses only were administered, the effect of which was to deprive him of consciousness, but he did not sleep, he raved and walked about his room the whole night.

The following day, Friday, he was worse, tremor increased, constant muttering, though when spoken to he conversed rationally on whatever subject was started. He stated there were two little devils playing the drum on his head, and that they kept up such a noise he could not sleep. The eye exhibited greater wildness and less fear than last night, the pulse was the same, 110, but fuller and more bounding, bowels not open. I prescribed two blue pills rolled in croton oil, to be taken immediately, and at night the following draught:—

R Spt. æth. sulph. ʒii.  
Chloroform. ʒi. M.

This draught to be repeated every second hour until sleep was induced. Owing to a mistake the patient did not take the pills till eight o'clock p.m., and half an hour afterwards the draught was administered; the pills operated rather briskly, both up and down, an hour after they were taken, and the draught was not repeated.

Saturday, 18th: Found my patient somewhat better, although he had had but one draught of the chloroform, still through the night he had dozed once or twice for a few minutes at a time. The symptoms not being urgent, I ordered porter to be taken during the day and nourishment. Visited my patient at nine p.m., determining to administer chloroform myself and watch its effects.

I gave three teaspoonfuls of a mixture composed of chloroform and spirits of sulphuric ether, in the same proportions as above; in a few minutes he complained of drowsiness, he closed his eyes, and became perfectly tranquil, the respirations became deeper and slower, the pulse fell from 96 to 62. To keep up the action I held the bottle to his nose for a few minutes; I watched him for half an hour, during which time he appeared to be in a natural sleep. This state lasted for about three hours. At leaving, I

directed the draught to be repeated in two hours if necessary, but my instructions were not attended to.

The day following, Sunday, he appeared much refreshed, less tremor, pulse 72, had eaten a hearty breakfast. I did not repeat the chloroform through the day; that afternoon he slept for an hour and a half, and at night I again visited my patient, and again administered the chloroform and ether as before; a single dose threw him into a profound sleep, from which he did not awake till six o'clock the following morning. From this time he gradually recovered, slept naturally and well without the use of chloroform; the only unpleasant symptom noticed was headache, which came on for two or three mornings afterwards, and lasted for some hours; this appeared to be relieved by porter.

The second case which fell under my observation was one of quite a different character.

Mr. S., labouring under an attack of delirium tremens, brought on by a debauch, came under my care 2nd October, 1852. When I saw him there was considerable anxiety, great tremor, the eye wild and staring, features bloated and swollen, pulse 120, full and bounding, tongue furred, bowels constipated, had not slept for two nights. I administered two drops of croton oil immediately, and prescribed the following mixture:—

Tr. opii, ʒii.  
Ant. pot. tart. gr. iv.  
Aqua, ʒiv. M.

*Dose*, a tablespoonful to be taken every three hours. The croton oil operated five or six times, and after the first dose the antimony was borne by the stomach.

This treatment was continued up to the evening of the 4th, when, as there was no improvement nor tendency to sleep, I determined to employ chloroform, and accordingly prescribed the following:—

Spt. æth. sulph.  
Chloroform. aa. ʒ½. M.

*Dose*, a dessertspoonful to be taken every two hours until sleep is induced. After the second dose my patient fell into a quiet slumber, which lasted six hours. The following day, the 5th, he was much better, countenance improved, eye less staring, much less tremor, pulse 88, bowels had been moved that morning. I ordered the chloroform to be repeated at night. After the first dose he slept, and did not awaken till the following morning, when he felt much refreshed, and quite himself; he got up, dressed, and took a short walk; being fatigued on his return, he laid down again and fell into a sound sleep, which lasted three hours. I ordered the chloroform to be repeated if necessary at night, however he slept all night without it; from this date he recovered rapidly.

Chloroform has been frequently employed in the form of inhalation with advantage by Dr. Todd and others. In the *American Journal of Medical Science* for January, 1852, Dr. Pratt, of Baltimore, published two cases of delirium tremens, in which the internal administration of chloroform was attended with most marked success.

Since preparing this paper, I have read another case of delirium tremens published by Mr. Butcher in the DUBLIN MEDICAL PRESS, in which the internal use of chloroform was attended with like success. Mr. Butcher draws attention to the lowering of the pulse when the perfect effect of the medicine was produced. This was most marked in the first of the above cases, the pulse fell from 96 to 62, it never rose above 76 while the patient was under treatment. In the second case, I had not an opportunity of observing the immediate effect of the medicine on the heart's action, but the pulse fell from 112, which was the number of pulsations previous to the exhibition of the chloroform to 88, which was its standard the following morning.

The foregoing cases, though by no means severe or alarming in their character, yet serve as further evidence of the successful employment of chloroform internally in the above class of diseases. In the first case opium had a decidedly injurious effect, all the symptoms were aggravated, at first I felt at a loss how to act, but having read Dr. Pratt's cases, I determined to adopt the same line of treatment.

Another point I would draw attention to; in the one case, the disease was brought on by want of an accustomed stimulus; in the other, the attack followed excess of the stimulus. In both the symptoms were peculiar, and in both the result satisfactory.—*Canada Med. Jour.*

#### EXTRACTION OF A HAIR-PIN FROM THE BLADDER OF A FEMALE.

On the 1st of April, 1852, M. Fantozzi was called on to see a woman, aged 20, who, for the last four months, complained of frequent desire to pass water, and severe pain especially accompanying the last drops of urine. The urine was turbid, depositing a sediment, and sometimes bloody. After some denials, she confessed that one night, while turning in bed, she felt a body, which she thought was a pin, which had fallen from her hair, penetrate into her urethra. This avowal rendered the nature of the accident apparent. After some trials with a sound, the presence of a foreign body in the bladder was demonstrated, which, in tilting against the catheter, gave the sensation of a metal.

M. Fantozzi tried, but without much hope of success, to extract it by means of a small pair of polypus forceps. These attempts only increased her sufferings. He then had recourse to the instrument invented by M. Belluomini, and the description of which we have formerly published (*Gazette Médicale*, 1851, page 569), under the name of "Cysticamptulque."

On the 12th of April, having allowed the urine to accumulate so as to distend the bladder, he introduced the instrument, but was unable to meet with the foreign body. On the morrow he renewed his trials, and succeeded in seizing the pin. He then so applied the force as to double the pin into the end of the canula, and to conceal it within it, and extracted it without pain or danger to the patient.

Although it had remained four months in the bladder, it retained its original flexibility. The calcareous incrustations were deficient in several points, and where present, were very thin. Probably these concretions were disintegrated as fast as they were deposited.

There ensued after this operation merely a slight irritation of the canal, owing to the reiterated introduction of instruments. No fever or any other accident disturbed the usual course of recovery.—*Gazetta Medica Toscana in Gazette Médicale de Paris.*

#### CASE OF HIDDEN SEIZURES, FOLLOWED BY EPILEPSY AND MANIA.

By MARSHALL HALL, M.D., F.R.S.

Mr. D—, "aged 53, engaged in business pursuits and calculations from an early age; . . . enjoyed excellent health until October, 1848, when he frequently complained of declining health, for which he had taken country lodgings, exercising himself a great deal by sea-bathing, and walking four or five miles before breakfast, by order of his doctor, who considered that he required pulling down." Mr. D— often complained of "his tongue and lips, which were sore, but from what cause he never could discover, nor did any one even suspect what his disorder really was" until his marriage. This took place in February, 1849, and "about three nights after, Mrs. D— observed that in his sleep he had a slight fit. These fits came nearly every night, but for some weeks only one during the night . . .

. . . . . Becoming more severe they returned every fortnight for some months, and were six or seven in number, until the last attack (June, 1852), when he had ten severe fits through the night, and bit his tongue severely." No one had observed these attacks but Mrs. D—, as they had always occurred during the night. The fits are always preceded by "a sort of smacking noise made by the lips and tongue, sometimes by a scream; the lips then turn purple, and the face deadly pale; he stretches out his legs perfectly stiff; his fingers are clenched, his features quite distorted; his eyes turned up; he bites the right side of his tongue and lips, and his mouth bleeds from the bite, but never foams; his neck is quite stiff, and he is perfectly insensible of uncontrollable evacuations. After the fit goes off, a cold perspiration breaks out over his head and face,

and he falls into a deep sleep, with heavy breathing, which lasts about an hour, when another fit comes on, and so on through the night. The whole day after he sleeps, and if he does awake, his eye is dull, and his mind appears unsettled. His memory has been greatly affected, things of yesterday appearing like years ago. He complains of little or no headache, unless the attack has been very severe, and even then it soon passes away. For days after an attack his spirits are very low, and he is in a state of great despondency, but he is naturally of a very nervous anxious disposition. The day before an attack he is generally irritable about trifles, and unhappy; although occasionally he is quite the reverse, being sometimes in high spirits."

A subsequent letter contains an account of some interesting phenomena:—"Yesterday, being exactly a fortnight since the last attack, Mr. D— dined at three o'clock, being not very guarded in what he ate, and drinking a little brandy in cold water. Immediately after dinner, he lay down on the sofa, when a fit came on; he turned very pale, and his lips purple, but beyond a slight twitching of the mouth and fingers, he had no convulsions. When sufficiently recovered to walk, he went to bed; he had then three fits (about half an hour between each) exactly like the first, without (general) convulsions, and all this time he was lying upon the left side. After the fourth fit he turned over on his right side, when he was seized almost directly with severe convulsions; and as the fit went off he slept a little, and moved again to his left side. When in this position he had another fit without convulsions. This was at nine o'clock, after which he slept quietly, lying in the same way till between three and four on the following morning, when he again turned over on his right side, and soon after had another fit, with severe convulsions, beginning with a loud shout. This was the last, and, after a good sleep, he appeared almost as well as usual, quite collected, and complaining only of occasional shooting pain in the head."

Soon after this letter was written, Mr. D— "became quite delirious, and in the following morning was in a fearful state of insanity—violent in the extreme, and obliged to be placed in a private asylum. He slept for the first time last night (three nights having intervened), and now eats heartily, but reason appears quite gone, though he is quiet and childlike. This is the termination of his sad disorder! His mouth is filled with a small white blister; altogether he appears in a most fearful state." At this time Dr. Hall's opinion was that the insanity would be of short duration. Acute mania, when the result of commencing epilepsy, is (like coma) of a transient character. When induced by long-continued epilepsy, its import is far more serious. The prognosis was correct, for, sixteen days later, "his reason has returned, although he is beginning to complain of the same pain in the head. . . . He appears flighty and unsettled. It is now nearly three weeks since his last attack, and all the usual symptoms are showing themselves previous to another."

Two attacks have occurred since this time, but "the balance of the mind is now quite restored."

This case requires no comment to enhance its interest. I would only suggest that in the diagnosis of obscure affections of the general health, attended or not attended with anomalous symptoms of disturbance in the functions of the nervous system, the greatest care be taken to ascertain whether any "hidden seizures" have occurred; and that for this purpose, and with a view to their discovery, the closest scrutiny is required of all the morbid phenomena: for example, the state of the tongue and lips, and of the pillow on which the patient has slept; and, if possible, the sleep should be watched, not for the purpose of diagnosis, but, as Dr. Hall has suggested, to prevent it from becoming too profound (by the judiciousness of a well-trained and trustworthy attendant), and thus to ward off the attacks.

The posture of the patient in this case appears to have borne some definite relation to the severity of the attack. This affords another hint for the observation and treatment of such diseases.

The state of mind prior to the attack is of great interest. Mr. D— sometimes was unusually cheerful. An intelli-

gent child, aged nine, now under Dr. Hall's care, exclaims frequently before its seizures, "I am so happy!" The emotions require as careful attention as the diet. The nervous system must be treated, not only by means of the body but through the mind.—*Lancet*.

#### CASE OF BLACK CATARACT.

In May, 1851, M. Alessi attended an old woman, æt. 76, completely blind of the left eye, and scarcely capable of seeing her way with the right. The iris was of a dark or russet colour. The impairment of vision had commenced six years previously by a cloudiness which gradually increased. In the left eye, the iris was very sensible to the stimulus of light, though the patient could not at all distinguish objects, yet she suffered a little when exposed to very strong glare. The field of the pupil was quite black. By holding a light before it, one image only was reflected—viz., that caused by the reflexion from the cornea. A surgeon present at the examination, supposing that the case was one of amaurosis, Alessi directed his attention to the following facts:—1st, that none of the symptoms of amaurosis, such as spectra, headache, &c., were present; 2nd, that the iris was under the influence of light; 3rd, that when in a darkened room, the patient could see much better than with bright light; 4th, that the dark appearance in the eye was of a dull dusky colour, which is not observed in amaurosis; 5th, finally, that an amaurotic eye reflects three images of a light placed before it. To complete the diagnosis, Alessi dilated the pupil with belladonna, and could perceive at the circumference of the lens two points, where the black tint was less marked, and which appeared like two little stains of a rusty colour.

On the 11th of May, the operation of extraction was performed, and a black cataract withdrawn. The fragments of capsule which came out after the lens were black, but much darker than it, which was of a reddish black. Since deprived of its capsule, and macerated in alcohol, the lens has in a great measure lost its dark colour, but at the time of operation, and when invested by its capsule, it resembled a flattened bay berry. Immediately after the operation, the patient could discern small objects. At the end of twenty-eight days she was quite well.—*Bulletino delle Scienze Mediche*.

The ghost of a black cataract has been haunting the study of the ophthalmologist time out of mind; never to be caught, and seldom to be perfectly seen. Here it is again, "the field of the pupil was quite dark," "the dark appearance was of a dull dusky colour," "a black tint," "a reddish black," "a dark colour," "which it lost by maceration in alcohol," and as like a "flattened bay berry" as a sea-serpent is like a whale.

#### FIVE CASES OF PERSONS STRUCK BY LIGHTNING.

In five men who suffered from this accident, M. Minourid observed burns presenting black eschars, with destruction of the epidermis, rete mucosum, and of a part or the entire thickness of the dermis, covered by a dark-coloured phlyctenæ, surrounded with an erythematous redness; the eschars were large, irregular, ill circumscribed, oval, or round, separated from each other by spaces of inflamed skin; no part of the body escaped, but they were particularly well marked on the outside of the lower extremities. It is remarkable that nowhere did the burn extend deeper than the dermis (the burn of the fourth degree of Dupuytren). Would it appear, then, that the subcutaneous cellular tissue is a non-conductor of electricity? Of ordinary burns, those which most resemble the effects of lightning are caused by gunpowder explosions; but the latter differ essentially, by bearing the marks of the grains of powder in the skin. In one of these men who died instantly, the writer observed that, though it was then the month of December, and the body had been left during the night merely covered with a cloth, and exposed to the air, yet after a period of thirteen hours, it was yet warm.—*Annali Universali di Medicina*.

#### ON THE EFFECTS OF CARIOUS TEETH.

By A. ROBERTSON, D.D.S., of Manchester,  
New Hampshire, U.S.

(Read before the American Society of Dental Surgeons.)

In the dissertation, which, by your appointment, I shall read to you to-day, about all that I have proposed to myself to attempt, has been to say enough to elicit some attention to, and if I may, to call forth some remarks, by the gentlemen of this Society, upon a subject, which, although for some years past, I am aware has received a great deal of attention by many of our best dentists, and perhaps by all the members of this Society, still seems to me to be deserving of far more attention than even now is usually given to it, as I believe, by dentists; and especially by the medical profession; because I know that it is not an uncommon thing for patients who are suffering from irritable lungs, from "nervousness," from marasmus, or from other debility, to be recommended to the country for change of air—for purer air; when they take with them—are allowed to take with them—a perfect cesspool of filth, containing matter both animal and vegetable, constantly fermenting and decomposing, and emitting nauseous gases, sufficient to contaminate all the air about them (unless it be to their windward in a gale), and through which all the air they breathe must pass; because I have frequent occasion to know that patients are often treated, by medication, for dyspepsia, for bronchitis, and for phthisis pulmonalis, when the commencement of the alimentary canal and of the trachea is in a state of constant inflammation or irritation from the effect of diseased and decomposing teeth; the whole nervous system disturbed by the same cause, and every particle of food taken into their stomachs, and every breath of air taken into their lungs, vitiated and rendered unwholesome by noxious inhalations, or by the admixture of disordered and unhealthy saliva; and all this train of evils allowed to remain uncorrected—perhaps unheeded; because I hear a great many complain of being troubled with, and of having been treated for, neuralgia, where there is obvious nervous irritation produced and constantly kept up by dead roots, or by badly diseased teeth, and with no attempt to remove the cause; because I often see and hear of treatment by poultices, by epispastics, and otherwise, for tumefactions of the face (sometimes called, though entirely unmeaningly, ague of the face), without attempting to remove or so much as to inquire into the cause. I say that it requires far more attention than, as I believe, is usually given to it, and especially by the medical profession, because I am not aware that the influences of diseased teeth upon the general health is scarcely alluded to in any of the works on medical practice, or in any of the lectures in any of the medical colleges; and because I have heard many physicians, and some of them eminent in their profession, say, "I know nothing about the diseases of the teeth."

Now, all this might be, in some measure, excusable if the teeth were isolated organs—if they had no connexion with any other part of the system. But it must be remembered, that although, in their chief substance, they have but a low degree of vitality, are not highly organized, still each tooth has at least one branch, and some as many as four or more distinct branches of nerve supplied to them, and that they are placed in that most important cavity—the mouth, forming in part and guarding the entrance to the alimentary canal and trachea; through which passages almost all substances of nutriment and of vivification are received; and that they must, therefore, both by sympathy and function, produce important influences upon the whole organization. Have I not, then, occasion to say, that, "as I believe," the connexion between the diseases of the general system with, and their dependence upon, the diseases of the teeth, usually receives far less attention than the importance of the subject demands. And may their diseases and influences be overlooked or neglected by dentists or by physicians with impunity? Let us see.

A physician is called to a patient labouring under severe fever, with hard, frequent pulse, restlessness, thirst, pain in the head, and intolerance of light. At the first glance, he perceives that an eye is inflamed; and, on inquiry, finds that not many days before a particle—a very minute particle—of sand, or of metal, has been blown or cast into and lodged upon that eye. The cause of this great derangement of the whole system, this pain, this thirst, this fever, is at once explained. But does he commence treating those symptoms of general derangement of the system with antiphlogistics or refrigerants, without first removing the cause of that derangement—to wit, that minute particle that caused that local inflammation? Surely not; for every physician certainly knows that well-established, that obvious first principle of surgery and of medicine, that to treat any disease successfully he must first remove the cause.

The physician may, in like manner, be called to a patient who is in the utmost agony. His appearance frightful; horror depicted in every feature; his eyes distended and bloodshot; his head thrown back, while his neck is drawn forward; the sterno-cleido-mastoideus muscles, by their rigidity, stand out prominent like broad thongs of raw hide upon his neck; the muscles of his abdomen present to the hand the feel of boards beneath the skin. In a few hours, perhaps, death comes to relieve the sufferer: the scene is closed. But the physician's inquiries have revealed the fact that his patient had, not long previously, stuck a little pin, or a small splinter of wood, in his hand or his finger, or a nail in his foot. The matter is all satisfactorily explained now. A minute branch of some comparatively unimportant nerve in a remote part of the system has been wounded: the case is tetanus.

Is it then unreasonable to suppose that a tooth so far decayed that its pulp is exposed and inflamed, may produce disturbance beyond the local seat of disease? And more especially if that tooth is, or if many teeth are so far decayed that their whole crowns are gone, the vitality of their roots destroyed, but they still sticking in their sockets, or in the gum only, and producing inflammation and suppuration, little, if any, less than so many splinters of wood would do, may be the cause of general nervous irritation, of fever, of death.

That such is the fact, that diseased teeth do produce, directly or indirectly, almost all manner of diseases, and their ultimate consequence—death, numerous examples might be quoted to prove; but I shall not now make quotations. I intend only to refer to a few things that I have observed in my own practice, and I will not weary you with many.

Neuralgia would seem to be a very common, almost a fashionable disease. I have seen a great many cases—probably many hundreds—where patients have told me that they were, and for a long time had been, troubled with neuralgia; and many who had been treated for it by medication; but I do not now recollect but very few cases, perhaps not more than three or four, of facial neuralgia, where the cause could not be directly traced to diseased teeth, or dead roots of teeth; nor where a proper treatment to restore them to health, or, if they were past such restoration, their removal would not cure the (very improperly) so-called neuralgia. I very well recollect the case of an old gentleman in Massachusetts, who, about two years ago, wished me to examine a lower bicuspid tooth that gave him a great deal of trouble. On examination, I found that the alveolar process and gum had very much receded from the tooth, that it was, in consequence, dead and very loose, and producing a very considerable degree of inflammation. I advised its removal, and with my fingers (for I had no instruments with me) extracted the tooth. Not long afterwards, the old gentleman sent me word that I had not only cured him of his sore and aching tooth, but also of a rheumatism in his arm that for a long time he had been troubled with. We have a number of cases reported in our journals and books of dentistry of a similar kind; but as I am aware the pathology of rheumatism is very well understood, that the conditions

on which it depends are very fully known, I do not pretend to say that I think diseased teeth are a common cause of rheumatism, or that they ever are a direct cause of that disease. I doubt, indeed, if they ever are; but this I do believe and say, if the system is predisposed to rheumatism, or almost any other disease, diseased teeth may, and probably often do, develop it. It is as well established a fact, perhaps, as almost any in the science of medicine, that individuals may be hereditarily predisposed to phthisis—be even born with tubercles in the lungs; but by carefully avoiding whatever might tend to develop the disease, as all depressing agents and circumstances, excessive excitements, and nervous irritations, they sometimes live to a good old age, and these tubercles remain dormant. On the other hand, the most careless observer knows that in those thus predisposed numerous and even slight causes (as a little exposure to sudden changes in the atmosphere, a wetting of the feet, night watching, continued anxiety or grief, and the like) develop it in all its fearfulness, and its almost certain result. That the nervous irritation from diseased teeth may do this, Dr. Bond, in his "Dental Medicine," quotes one or two very interesting cases to show. A few weeks since, a friend of mine, now a dentist, related to me a case that came under his observation some sixteen or eighteen years ago, that I think worth relating for its bearing on this point. It was of a young lady, who at the age of 20 was supposed by her physician, her friends, and herself to be far gone with consumption. About this time, a young gentleman, who was a medical student, and who had paid some attention to dentistry, visited her father. On being allowed to examine her mouth, he found her teeth in a very bad condition, and recommended that several of them be extracted, and some be filled. She at first objected, on the ground that at the most she could live but a very short time, and therefore she thought it unnecessary to submit to the pain of such an operation when it could be of so little importance to her. Her friends, however, persuaded her to allow him to remove those that were past restoration. From that day she began to improve; her health was soon entirely restored, she was afterwards married, and about a year ago, when my friend last heard of her, she still enjoyed good health. But, as I have said of rheumatism, I do not suppose that diseased teeth directly produce consumption, but that the irritation and depression and loss of rest and of sleep caused by them, may, and probably often does, develop this disease, I have no doubt.

But without dwelling on diseases that are, or may be, indirectly produced or developed by these causes, I shall venture to say that there are doubtless many, and serious diseases, produced directly by decayed teeth.

I have already alluded to a large amount of disease of a very painful character, under the denomination of neuralgia, where this agency is most palpable, direct, and unmistakable; and I scarcely need allude to the various tumours, some of them of the most malignant kinds, about the jaws and the glands contiguous to them, caused by the irritation of decayed teeth. They are not of very unfrequent occurrence, nor of doubtful origin.

That distressing, and often fatal disease, bronchitis, there can scarcely be a doubt, is frequently produced, or at least greatly aggravated, by inflammation extending from the gums to the fauces and throat, as well as by the debility occasioned by the disturbed sleep, the want of rest, and the impure air of which decayed teeth are the certain cause.

But there is another most annoying and troublesome disease, perhaps I should rather say, class of diseases, not always very clearly defined or understood, but known by the common, the very popular designation, dyspepsia, where the influences of decayed teeth are most direct in producing it. They are, in my belief, by far the most common cause of dyspepsia. Their influences here, too, act in several ways. Where an individual has many badly decayed teeth, the food is usually but slightly masticated. It is, therefore, not sufficiently disintegrated, nor properly mixed with saliva; it is not properly prepared for the stomach. It is indeed very badly prepared for the stomach,

for the little saliva that is mixed with it is impure, vitiated. All the saliva, in fact, that passes into the stomach, whether with food or otherwise, is of an impure, vitiated, irritating character. The food is, therefore, imperfectly digested. Decay of the teeth, being, as I believe, and as I think is now generally believed by those who have given most attention to it, to be almost, if not altogether, simply a decomposition of their substance, we have, therefore, in such cases, the saliva constantly mixed with the decomposed and putrid animal matter. And where the use of the brush is neglected so that the teeth become loaded with tartar, as often happens, we have vegetable matter added to this decomposing putrid mass of filth. How irritating! How nauseating! How disgusting! The gas arising from such decomposition, renders all the air taken into the lungs impure, and prevents the proper arterialization of the blood. That they constantly irritate the nervous system, I need not here repeat: thus marasmus is produced by badly digested food, by impure, improperly arterialized blood, and by constant nervous irritation.

So fully do I believe dyspepsia to be a natural result of these causes, that I rarely, if ever, look into a patient's mouth containing many badly diseased teeth without expecting to find that patient troubled, more or less, with dyspepsia, and my expectations are almost always verified by inquiry. I recollect a marked case of dyspepsia from decayed teeth, that in my practice came under my observation about three years ago—a sketch of which I will give you. A lady of about 30, married, and the mother of two or three children, came to consult me about her teeth. She was then, and had been for some years, suffering badly from dyspepsia; her complexion was sallow, almost of a cadaverous hue; she was feeble and much emaciated. On examining her mouth, I found every tooth in her upper jaw (the whole sixteen) badly decayed, and the gums inflamed and turgid. I recommended the removal of all those teeth, and with her consent proceeded to remove them all, which I accomplished at one sitting of perhaps ten minutes. Her health from that time began to improve, her strength to increase, her complexion to brighten. She is now a robust healthy woman. Similar cases are by no means unfrequent, and to attempt the cure of such a case by change of scene or of climate, by rest, by exercise, or by medication, without first removing that cause, would be very like filling a sieve with water—a hopeless and a tiresome task.

Before quitting, I must say a little more in relation to the miasmatic phase of this subject. Our legislators enact laws, and our municipal authorities appoint officers (boards of health) whose especial duty it is to see that no filth, and particularly that no animal or vegetable matters be thrown upon or left in the streets and alleys of our towns and cities to decompose and produce miasmata; and that vaults and cess-pools be not left open to vitiate our air, and render it unhealthful; and all this very properly, and we freely pay our taxes for the making and the executing such laws. The health of the community requires it, and shall the conservators of the health of the people—the physicians or the dentists, then overlook or disregard this far more concentrated miasma, and its source (decayed and decaying teeth) situated as it is in the very gateway of life of their patients?

Although I may possibly place my estimate of the evil influences of decayed teeth upon the general health of the system too high, still I think that this at least must be admitted. The cause of a very large share of all the diseases to which the human system is subject, depends in some way either upon unwholesome food (and I see very little difference in the result, whether it is so in itself, or is rendered so in the eating of it), upon miasmata, or upon nervous irritation; and therefore many of them may be caused, or if not caused, may be developed by the vitiation of the food, by the miasma, or by the nervous irritation produced by dead and diseased teeth, and that it must be at least safe practice in the treatment of almost all, if not all diseases, and judicious prophylactic treatment as well to remove or allay all sources of nervous irritation and of de-

pression: and I will further hazard the opinion, that the teeth and their appendages are more frequently the seat of nervous irritation than any other portion, if not than of all other portions of the organization, and that if medical gentlemen, when investigating the nature and the causes of the diseases that they are called in to treat, will make it a point carefully to examine the condition of the mouths and particularly the teeth of their patients, they will there find a far more fruitful source of disease and of its development than very many of them at least suppose.

It may be said that these remarks are calculated for physicians, for general practitioners, rather than for dentists. Be it so. I would speak to them on this subject; and I know of no place from whence I can speak to them with more effect or with better prospect of being heard than in and through this Society. But if they, our elder brothers, overlook or disregard this subject, it is the more important that we, in our humbler sphere, should pay the more attention to it; that although we may not be called upon to treat the diseases of which they are the cause, we may do, and be fully prepared to do, all in our power to prevent their occurrence.—*Amer. Jour. of Dental Science.*

#### PERMANGANATE OF POTASH IN DIABETES.

A GENTLEMAN, upwards of 60, residing in the country, had for several months been suffering from confirmed diabetes mellitus when I first saw him, two years and a half ago. In the course of the twenty-four hours he passed from ten to twelve pints of urine, the specific gravity of which was 1.035 in the morning, and 1.040 in the evening. The patient was greatly emaciated, and he suffered severely from constant pains in the back and thighs, and from increasing debility. After he had perseveringly tried various remedies for nine or ten months without deriving any benefit, I began, in August, 1850, to give him the permanganate of potash in solution, in doses of two grains, which were afterwards increased to three grains, three times a day. In the course of a few days a visible improvement took place; he felt better; the quantity of urine began to diminish, and the thirst became less troublesome. These favourable symptoms were soon followed by some return of appetite, and a gradual increase of strength. This amendment went on without interruption; the medicine was continued for three months, until the following November, when all medical treatment was discontinued, as the patient felt quite well, and the urine was reduced to its natural amount. A remarkable fact must, however, be mentioned, that at that time, notwithstanding the restoration of the general health, the urine still contained a considerable quantity of sugar. I am not aware whether this state still exists, but the patient's report to me a few days since ran thus:—"I pass less than a pint of urine during the night, somewhat more during the day; the pains are gone, and I can walk a fair distance without fatigue." The dose of permanganate of potash which I have generally found to agree best with the stomach, is from one to three grains in solution, and it should be given in three or four tablespoonfuls of water three times a day, shortly before meals.—*Mr. George Sampson in Lancet.*

#### PAGLIARI'S HEMOSTATIC.

THIS nostrum has recently excited a great deal of attention both in France and Italy; and from the reports of Sédillot and others, we are inclined to think that it may really be possessed of considerable power in staunching blood from small or retracted vessels to which the ligature cannot be applied. When the hemostatic is added to blood in a glass vessel, a dense blackish mass is formed. For some time, Pagliari concealed the composition of his nostrum; but he has now published the following as the formula according to which it is prepared: Take eight ounces of tincture of benzoin, one pound of alum, and ten pounds of water; boil them together, and stir the compound for six hours in a glazed earthen vessel, adding water so as to supply the loss by vaporization, and to allow ebullition to continue. Afterwards, filter the fluid, and preserve it in stoppered bottles. Its taste is styptic, its odour aromatic, and its appearance like limpid champagne.—*Association Medical Journal.*

## REVIEWS AND NOTICES OF BOOKS.

## AN INTRODUCTION TO CLINICAL MEDICINE.

By J. H. BENNETT, M.D., F.R.S.E., Professor of the Institutes of Medicine and of Clinical Medicine in the University of Edinburgh. 2nd Edition. Edinburgh. 1853. Foolscap 8vo. pp. 134.

THIS little work consists of six lectures, each devoted to a distinct method of investigating disease. It has been republished (the author tells us) with the object of facilitating the studies of the gentlemen attending his courses in the clinical wards of the Royal Infirmary of Edinburgh.

The first lecture contains directions as to the best method of interrogating patients, and remarks upon the principal points to be attended to in arriving at a knowledge of the seat of the disease; followed by directions for properly carrying out post-mortem examinations.

The second lecture is devoted to percussion. The author recommends a pleximeter and a hammer for this purpose, in preference to the fingers. The pleximeter which he uses is a modification of M. Piorry's; the hammer is the invention of M. Winterich; figures of both are given. The advantages which Dr. Bennett considers these instruments to possess over the fingers, are—"1st. That the tone produced in its clearness, penetrativeness, and quality, far surpasses that which the most practised percussor is able to occasion by other means. 2nd. It is especially useful in clinical instruction, as the most distant student is enabled to distinguish the varieties of tone with the greatest ease. 3rd. It at once enables those to percuss who, from peculiar formation of the fingers, want of opportunity, time, practice, &c., are deficient in the necessary dexterity."

In the third lecture auscultation is considered. In it a concise description is given of the sounds heard over the pulmonary and cardiac regions in health and disease; followed by some useful general diagnostic rules. The fourth lecture contains a description of the microscope, and practical rules for its employment in examining different tissues. We have next a lecture upon the principal applications of the microscope to diagnosis. In it the microscopic appearances of the "saliva, milk, blood, pus, sputum, vomited matters, fæces, uterine and vaginal discharges, mucus, dropsical fluids, urine," &c., are described and illustrated by numerous woodcuts.

The concluding lecture is upon the classification and diagnosis of cutaneous diseases. It contains an improved arrangement of these affections, founded upon that of Willan and Bateman, but much modified, and including two new orders—viz., "dermatozoa," depending on the presence of "parasitic animals," in which the author places scabies; and "dermatophytæ," depending upon the presence of "parasitic plants," to which the author has removed favus and mentagra from the order pustulæ of Willan and Bateman.

This little work cannot fail to prove of use to those for whom it is intended; and we are sure will become popular with the students in other schools besides those of Edinburgh, when its merits come to be known.

## IMPENDING DEATH BY CHLOROFORM:

## RESUSCITATION BY RAISING THE EPIGLOTTIS, AND DIRECT INSUFFLATION.

ONE of M. Ricord's pupils has just addressed a letter to this surgeon in *L'Union Médicale*, wherein he states that he succeeded in rescuing from the grave a patient of his (who was being asphyxiated with chloroform), by following M. Ricord's plan of resuscitation. The lady was having some verrucæ removed from the vulva, &c., and had been narcotized with the handkerchief and pledget of lint impregnated with chloroform within it. She was rather hysterical, and had had a fit when under the influence of chloroform some time previously. In this instance, narcotism was obtained after seven minutes' inhalation, and the handkerchief was removed from the mouth from time to time. After the first verrucæ were excised,

sensibility returned; chloroform was given again, and in four minutes the whole operation was finished, but the patient was pronounced pulseless, and the ear applied to the chest could perceive no cardiac sounds. The operator, in great alarm, passed his finger into the posterior part of the patient's mouth, and found the epiglottis covering the entrance of the larynx. By pulling the tongue forward, and pressing the base of the epiglottis, the larynx was freed, and the young surgeon then applied his mouth upon the patient's and vigorously insufflated the lungs, whilst one of the assistants (there had been two all along) pressed down the parietes of the thorax. This was repeated twice for five minutes at the time; and the patient, who a few moments before was a mere corpse, gradually recovered, and has done well. *Lancet.*

## MEDICAL PRESS.

SALUS POPULI SUPREMA LEX.

DUBLIN: WEDNESDAY, JANUARY 19, 1853.

## THE PROVINCIAL SURGEONS OF ENGLAND.

WE cannot better remind the Provincial Surgeons of Ireland of their duties ■ a body (numerically at least, the most important in the medical profession in this country) than by holding up to their view for imitation the Provincial Surgeons of England. Amongst other results of the organization effected by these gentlemen in the sister country, is the establishment of a weekly journal of their own, ■ the following extract explains; but there are others of much greater importance which might ■ easily be attained by a similar Association in Ireland. It is none of our business to applaud them for establishing a journal, and it would not be good taste to complain of their doing so: people, too, might say that we were afraid it might lead to such ■ thing in Ireland, to the prejudice of the MEDICAL PRESS, if we objected: so let that pass. We merely call attention to the matter by way of hint, and may perhaps return to the subject hereafter:—

Twenty years ago, the Provincial Medical and Surgical Association held its first meeting at Worcester, at the invitation of its founder, Sir Charles Hastings, who then and there rallied around him some of the most eminent physicians and surgeons practising in the provinces. The foundations were broadly laid upon the principles of justice, honour, and fraternity; and time has shown that they were ■ securely as they were wisely planted. During the long period which has elapsed since our Association was established, the medical profession has undergone great and striking changes in its educational and social aspects: the apothecary of the olden time has gradually been displaced in almost every town and village by the well-informed practitioner: the highest accomplishments are no longer the monopoly of a few; and there is scarcely a place in the kingdom in which even the poorest cannot command the services of men more competent to grapple skilfully with the emergencies which occur in the practice of medicine, surgery, and midwifery, than the foremost physicians and surgeons of no very remote a period. Along with the improvement in skill, there has also been an evident advance in the tone of the profession. While we willingly admit that this wonderful reformation has chiefly resulted from the licensing boards having step by step enlarged the course of study required from candidates, and rendered more searching the examinations to which they were subjected, we are equally convinced that the proceedings of the Provincial Association have in no small degree contributed not only to accelerate the happy changes to which we have adverted, but by manifesting them to the public, to give to the profession a social status and a political weight which it never previously possessed. At this moment, unchartered though we be, our influence is ■ powerful in high places as that of any of the old medical corporations; and it is well known that no measure of medical reform could pass through parliament, which ■■ opposed by the Provincial Medical and Surgical Association. From the first, but especially in later years, the Association has exercised an invigorating and pu-

riety influence within its own ranks, and has often extended these benefits to the profession at large. Members guilty of irregular practice and unprofessional conduct, when discovered, have been energetically proceeded against; and some offending brethren have been admonished, while others have been expelled, or have been allowed to resign to save themselves from this extreme penalty. The anniversary general meetings and the district branch meetings have greatly strengthened feelings of harmony and good-will, by bringing into personal contact brethren who would otherwise have remained widely separated from each other by space and the engrossing duties of practice; and in this way the pleasant friendships of youth and early manhood have been perpetuated, while many new and endearing ties of amity have been formed and cemented. The publications of the Association have also greatly promoted a spirit of scientific inquiry, original research, and accurate clinical observation. These, and such like, have been the noble objects for which the Association has uniformly contended, and in behalf of which we trust it may ever unflinchingly and zealously exert its power. But it is not only in the provinces of England—the original sphere of its operations—that the influence of the Association has been seen: its operations upon professional circles, and upon the public mind, have recently been as powerfully felt in the metropolis, and in Scotland, as in the English counties. One, indeed, of the most signal benefits which the Association is now conferring upon the profession is the extensive union which it is establishing among all the loyal sons of physic throughout the British empire, who are willing to enlist under the catholic colours of legitimate medicine. Our Association repudiates all party, sectarian, and selfish objects; and in proof, as well as in pledge, of the respect which is paid to this maxim, it is only necessary to mention that our list includes members from all parts of England and Scotland, practitioners of every class, and professors of almost every school. Here it may be well to state, that we interpret the motion adopted at Oxford, in July last, in favour of publishing the journal weekly in London, in place of fortnightly at Worcester, not as an expression of opinion in favour of radical changes, as was feared by some, who, for a time, doubted the soundness of that decision: but simply as a strong declaration of the necessity which the progress of events had imposed upon the Association, of pursuing the line of duty which had hitherto been acted upon, with that augmented vigour which a wider sphere of action required—a vigour which could only be effectively developed by greater frequency of publication, and by the possession of a literary and scientific centre in London, where editorial resources are more abundant, more varied, and more easily available, than in any other city in the world. While, therefore, you are this day addressed from another locality, and by another representative, there is no call to transfer your allegiance to another cause. On the contrary, you are invited to rally more closely than ever around the same worthy banners under which you have for the last twenty years, so consistently, so gallantly, and so victoriously contended. You are invited to assist us, while we endeavour to defend and to extend the good cause; so that, ere long, our Association may embrace within its pale every legal practitioner of medicine who is adequately impressed with the awful responsibility of his calling, and who desires to see a strong and impregnable wall of partition built up between the sons of legitimate physic and those marauding bands of impostors, whose only real medical creed is lucre, and who, under various sectarian denominations, recklessly traffic in the health and lives of a medically ignorant, and therefore easily deluded population. Under no pretext whatever, by name, allusion, or innuendo, shall we ever discuss, in our editorial articles, the alleged misconduct of any member of our body. The Association has laws and ethical tribunals before which such charges can be promptly brought, and impartially investigated. Until an associate be actually convicted of unprofessional conduct, it is assuredly the duty of the editor of this journal to take no part, for or against him, and also to save him from the publication of *ex parte* statements, which have often injured even the innocent. When the reports of cases involving ethical questions are officially transmitted to us by the general or local secretaries, they will be printed in that department of the journal which is devoted to "Association Intelligence." If disputes should at any time arise regarding the administration of the laws, or regarding points of order in the conduct of public business, we shall (editorially) withhold all expression of opinion. In such matters, it is clearly the duty of the Association or of its executive council, and not of the editor, to adjudicate.—*Association Medical Journal.*

## POOR-LAW MEDICAL RELIEF.

WE are often at a loss for information respecting the "Working" of the Poor-law System of Medical Relief in England, for the perusal of the Regulations of the Commissioners do not always afford it. From time to time we publish such extracts as the following from the English medical journals, finding them more explicit than the rules which lead to the results they complain of. It refers to the case of

An agricultural labourer on full wages; 8s. a week, with a family—viz., a wife, who had been ailing some time, and on the eve of her confinement, and two children. The second child, a boy, aged a year and seven months, had been ill since harvest with whooping-cough. On Friday, December 3rd, the child's chest symptoms increased to an alarming extent; worse on Saturday. On Sunday, the father applied for an order for the doctor, but did not see the overseer, who was at church. The next day, Monday, application was made to the relieving officer (this being his regular day for visiting this particular parish). Upon being satisfied as to the earnings of the man, this functionary refused the medical order. Application was then made to the overseer, who refused also. He could hardly do otherwise, as he knew the woman had but just come from the relieving officer, whose more immediate duty it was to give relief, if the case would justify his doing so. No order for medical assistance was granted, and early the following morning (Tuesday, one a.m.) the boy died. Application was now made for a coffin, which was granted by the very same functionary who refused medical assistance; but the fact of the child dying, and no medical attendance, was made known to the coroner, who held an inquest on December 10th, when a post-mortem examination was made, and the cause of death proved. The coroner adjourned the inquest till December 16th, in order to inquire the reasons why no medical man had attended the poor child. The relieving officer was summoned, and justified his refusal by law, by his book of instructions (not produced), and also by a specific verbal order of the guardians, which was that no able-bodied man could receive a medical order for himself or family; that if the family were destitute, they would receive an order to admit them into the union house; but that the law justified him in refusing medical aid in this man's circumstances; and that, in such cases, if he gave an order, it would be on his own responsibility, and that he might have to pay the expense of it, if the guardians at their weekly meeting refused to ratify or sanction his act. Now, in order, as it seemed to me, to justify himself still more, in cross-examining the witness who had applied to him for the medical order, he asked whether she had told him the same circumstances of the man's family when making the application as she had then stated before the coroner? This question led me to suppose that the specific verbal order did not really justify him so much as he wished us to think, but that a good deal must be left to his discretion. Then, again, he asked if application had not been made to the doctor, which was denied. Now, if he was justified by his orders, what need to ask these questions? I think by asking them he exposed the weakness of the plea he had set up—first, by appearing ignorant of the number of the man's family and means; and secondly, by endeavouring to shift the blame upon the doctor, if application had been made to any; or else he trusted that if application to the doctor was made, that the well-known humanity of the profession would not suffer a fellow-creature to die without some attempt at relief, although the natural guardians and parochial and poor-law authorities all combined to refuse to hold out their assistance. The jury found that the child died from natural causes, expressing indignation at the state of the law which could suffer a fellow-creature in this Christian country to die without medical means being obtainable. What is the law? Is there any? And if a poor man or any of his family are taken ill, is it legal to turn the union house into an hospital by ordering all those cases that can be removed to be so, instead of giving orders to the medical man of the district in which the sickness occurs? One union pays a pittance by way of stipulated salary or contract; another pays so much per case. Now, where the salary system prevails, medical assistance is granted with a freedom that must delight the philanthropist. There no man, woman, or child would be at all likely to die without having medical aid to try to stop the progress of disease, or at least to give relief where no cure can be expected. It appears, therefore, to me that the

only poor-law there is, is one of £ s. d., and that boards of guardians are at perfect liberty to make what laws they please; which, as they legislate naturally more for their own pockets than for the poor entrusted to their care, it is easy to see that their feelings and orders will be guided by the consideration of £ s. d., and that alone. Now, as government pays a share towards the union expenses (one-half, I think, of the medical expenses) is it to be credited that any board of guardians can be justified in so crippling any functionary under them, that he cannot do what seems a duty for fear of having to pay for his act out of his own private resources? If this functionary was liable to pay for the medical order, if he had granted it in this case, so should he be for the coffin which was so freely granted. But what false economy! Better surely pay a doctor his pittance than to have to pay for a coffin, and run the county to the needless expense of an inquest.—*Letter in Lancet.*

Here we have the practice, if not the law, as to the restriction of medical relief to mere paupers in England; but here in Ireland, we conclude, that no one would deny such relief because the applicant was "an able-bodied man," earning eight shillings a week only. We here complain of tenant farmers, small shopkeepers, and liveried servants, receiving gratuitous relief, while there it is grudging even to the mere labourer, which reminds us that the question is not without its difficulties. In the one case, the provision is grossly abused by an improper extension of it; in the other, as grossly defeated by a total denial. Some time must elapse and some patience be exercised before the right becomes defined, and in the meantime the Surgeon must use his influence to secure justice both to himself and the sick poor; forgetting neither the one nor the other. The following, which is from an advertisement, affords some insight as to the operation of the law, as regards remuneration for medical services, and will enable the Dispensary Surgeon to contrast his case with that of the Union Surgeon in England:—

The guardians of the poor-law union of Wilton are desirous to contract with a medical gentleman (duly qualified in accordance with the general orders of the poor-law board) to undertake the duties of a medical officer of the district comprising the undermentioned parishes, at a salary of £100 per annum. Surgical, midwifery, and vaccination cases to be paid for in addition. Population in 1851, 2297.

It is to be recollected that this is "a contract," and that medicines are to be supplied as part of it; but even so, the payment seems better than our £60 a year and excessive districts. To this, however, it should now be the business of the Dispensary Surgeons to apply themselves; for if an assimilation of the law and practice in the two countries should prove desirable, justice and expediency must be pleaded in behalf of such a proposal. A measure of this nature would of necessity involve an extension of the government grant, now confined to England, toward the discharge of salaries, and in this way might operate most beneficially. We throw out the suggestion now without more consideration, but we propose to return to it.

#### UNIVERSITY PRACTITIONERS.

If there be any truth in the following, the Medical Honours of the Universities are likely to be at a discount in the Diploma market, and simply perhaps because they are now mere honours, if even that same. The homely adage, "handsome is that handsome does," seems to be revived, and in future we are to have deeds not words to ensure success. Still we have our doubts, for there are extremes, and in discarding all honours we may find ourselves dishonoured. The admission of a low grade of practitioners into our body, through the agency of certificate shops and

grinding concerns, may prove but a bad remedy for the evils of obsolete institutions. COBBETT used to compare the English people to a measure of ale; "froth at the top, dregs at the bottom, and good drink in the centre;" and perhaps we shall presently have to apply the simile to our body:—

Does any one entertain the serious conviction, that the position of medicine in the world, and among the other learned professions, is only to be maintained by preserving a speculative alliance between an artificially created medical and surgical aristocracy and the ancient universities? He who still clings to this venerable fallacy, must indeed be oblivious of the course of present events. Does any one suppose that the medical body derives any considerable credit from the yearly infusion of the four or five graduates which the united resources of Oxford and Cambridge are able to produce? The College of Physicians has itself seen the necessity of abandoning that traditional connexion. The fellows are now no longer recruited exclusively from the ancient universities. The future credit of the college is felt to depend greatly upon the accessions it shall receive from the University of London. The time has gone by when the superiority of classes, the system of professional castes, can be supported by artificial and arbitrary distinctions. The only endurable aristocracy will be the aristocracy of talent. There can be no reason to fear that the rising generation of medical practitioners will not sustain the reputation of medicine. Out of the many who now enjoy all the advantages of an education, general and professional, carried to the highest attainable point, which in former times was the exclusive privilege of a few, there will still continue to arise men to vindicate the claims of medicine to an honourable place. If such men fail, as of necessity they must, to preserve the "unmixed intellectual character" which Dr. Alderson claims as having "hitherto belonged to the pursuits of pure physician and surgeon," the world will not consider that their minds have been debased, merely because they have made themselves useful in alleviating the sufferings of their fellow-creatures.—*Lancet.*

#### RIGHTS OF PRACTICE OF SURGEONS IN ENGLAND.

SOME "General Practitioners" in England, when closely pressed by a Surgeon not having an Apothecary's licence, endeavour to "trip him up" by denying his right to supply medicine to his own patients; but common sense and common interests begin to operate toward the defeat of any such monopolizing pretensions, as the following brief extract from a London journal of authority in such matters proves:—

A member of the Royal College of Surgeons can charge for medicine supplied in a surgical case, and recover the amount in the County Court. He does not by this proceeding render himself liable to the Apothecaries' Act.—*Lancet.*

#### KIRWAN'S CASE.

THE public sympathy displayed regarding this case has somewhat subsided, and has been replaced by curiosity excited by the new charges preferred against the party. With this we have nothing whatever to do; all that concerns us is the value of the evidence afforded by the body toward forming a judgment as to the cause of death; and upon that point we propose to submit to our readers in our next number a communication from an authority entitled to confidence, not merely on account of his acquaintance with the subject, but from his personal knowledge of the details of the investigation from the commencement. At the same time, we do not pledge ourselves to refrain from comment on the general bearing of the case, should any medical journal think it proper to discuss the matter more at large; for we have reason for thinking that something more than scientific investigations are in contemplation by parties proposing to handle the subject. We do not allude to any London contemporary, neither do we

care to say that we allude to any influence in particular; but we say this much by way of hint to those who may suppose that they can "do as they like with their own," regardless of what is due to the character of the medical profession. Whatever may be the final result of this affair as regards the convict, much good may follow from it as regards the management of similar cases hereafter. Coroners' inquests and criminal trials involving medical questions can no longer be conducted as they have been, without seriously compromising the characters of those responsible for the due execution of the laws. Are we to wait another half-century or so for a ROMILLY or a SUGDEN to reform this department, or are we to look quietly on while machinery is employed to defeat the very object for which it was originally destined? Respecting inquests, it may now be asked, whether they do not almost as often serve to screen the guilty as to protect the innocent; and of criminal trials, whether they do not as often lead to the acquittal of criminals as their conviction? We would not answer such a question in the affirmative, but we must confess that there may be some grounds for putting it.

### MEDICAL LIFE IN LONDON.

#### HALF-HOURS IN THE MUSEUMS.

London, January 8, 1853.

As we hinted some time since that in the new year we would "change the venue" from medical practice in London to a more agreeable subject—some half-hours spent in the museums. In redeeming our pledge, we hope not to injure the sensibilities of those for whose good anything here written has been intended. It is not every one who likes bitters: "Non omnes arbusta juvant." Many of our friends in London do not like the naked truth; but those of independent minds and truth seeking, care not what may be exposed. We have said enough, however, to explain why quackery and homœopathy, and every kind of periodic absurdity, finds footing in London. If our beautiful science is made a mean sort of trade we cannot blame the public slighting medicine and taking refuge in quackery. Our hospitals and societies are highly creditable, and quite on a level with the advances of medicine; but our science is all in holiday attire. While our young men and presidents of societies are discussing all the new facts (microscopic and otherwise), the practice of the vast mass of practitioners is crude, absurd, and barbarous. Chemists, and assistants without the shadow of diploma, set up shop wherever they please; and this is medicine in the middle of the nineteenth century in London! Many of these men not knowing the circulation of the blood, nitrogen from oxygen, and as much "at sea about crucifera" and botany as they would about Hindostanee. Medical education is superior in France, Ireland, and Scotland; but from our museums here, many interesting and valuable facts may be picked out.

Our greatest museum in London was founded by an Irishman, Sir Hans Sloane; the great College of Surgeons' collection by a Scotchman, John Hunter; while at the College of Physicians, poor Harvey was nine years illustrating his doctrine of the circulation, with preparations, all in vain. "He fell mightily in practice," we are told; and in London it was believed "that he was crack-brained, and all the physicians were against him." His "therapeutique way" was not admired, and he was left on the highroad to starvation but for King Charles. These facts, at least, should make us a little modest. It is good for us occasionally to think over the lives of such men. Hunter dying in debt, and his magnificent collection going begging, refused by this College of Physicians, and grudgingly received into its present situation. Sir Hans Sloane giving away thirty years' income as charity, but he himself now half forgotten.

Sir Hans Sloane was born, according to some documents in the library of his splendid collection at the British Museum, in the County Down, Ireland, at a place called Killileagh, April 16, 1660. He stated in his will that the collection he was bequeathing the nation was richly worth £80,000; it contained 200 volumes of dried plants in the form of a *hortus siccus*, 30,000 mineral and other specimens of great interest in natural history, with a library of 50,000 volumes, and 3566 very rare manuscripts. There are two pictures of this great and talented Irishman in the museum. One would like to see them more generally known. It appears from the little written of Sir Hans Sloane that it was in Ulster, in Ireland, he first imbibed that love of scientific pursuits that have since rendered his name, and we fear only his name, illustrious: in France and Ireland, in fact, was laid the foundation of his great museum. Like Hunter, Mozart, Goldsmith, Hadyn, Johnson, and a legion of other great men, we find Sloane in early years struggling a good deal with adversity. Before he was of age he had several severe attacks of hæmoptysis, which threatened him with an early grave, like Laennec, Bichat, and others; death, however, spared him till he had done his work. Stahl, Ray, and another great countryman, Robert Boyle, were then in the ascendant, all of whom were known to Sloane, and helped to form his mind. And yet who thinks amid the winged bulls from Nineveh, and the magnificent collection crowded at present in the huge building of the British Museum, of Sir Hans Sloane or Boyle. We think of Watt whenever we see a steam engine, because with one happy thought he has made it the last wonder of the world in a utilitarian point of view: the great workers in the mine of abstract science and philosophy, we disregard. In 1683, young Sloane set off for France, and there seems to have been delighted with the botanical collections and lectures of Tournefort, and spent a year collecting plants for the museum. We find him next going out to the West Indies, a young man, under 30, physician to the Duke of Albemarle, and in spite of many crosses and disappointments, still further adding to his specimens 800 species of rare and valuable tropical plants. These two collections form the first nucleus of the British Museum. It seems all this time he never forgot his native country, Ireland, and we should in all probability have those specimens now in Trinity College, Dublin, and the British Museum (which would be a great blessing) quite a different institution, but that Sloane got married to a very rich wife and settled permanently in London. In 1693, he became secretary of the Royal Society, and in 1727 was appointed physician to the king, and succeeded the great Newton as president of the Royal Society. George I. made him a baronet, and he died, at the age of 93, in 1753.

Of the life of the great founder of the Hunterian Museum we need say nothing; the facts of the eventful biography of Hunter are among the household words of the profession. He, too, was looked upon as an innovator like Harvey, and fought his way to his position among the greatest men that ever lived. Hunter or Harvey have no monuments in brass or marble in London; but they want none, their memories and great acts are enshrined in every good man's soul without the empty nonsense of colleges. Our American and other friends walking through the galleries of the museum, should recollect that it was Sir J. Banks and Lord Auckland rescued it from destruction, that poor Hunter's worldly chattels were all sold for debt—for debts incurred in putting the museum together, that the College of Physicians refused the museum as a gift, and that under certain favour it was offered a domicile by the College of Surgeons, whose income, from getting the hard-earned work of Hunter's life, was doubled after a little, so that in 1833, it was said to be over £10,000 a year, and £66,000 in hands; the government gave £30,000 to build the museum, and £15,000 for the preparations. With all this money, or a tithe of it, in Dublin, with another

Sir Hans Sloane, Macartney, or Carmichael, what miracles might not Ireland perform. Poor Hunter's life seems to have been one battle. He set out early under the guidance of his brother, with whom he soon fell out; in 1753 he goes to Oxford, laughs at Latin and Greek, and a little after we find him battling with the Monros and his brother. His next encounter was with Pott—a sort of Syme of those days, that every one thought it correct to have a tilt with. Our intention, however, at present is to say something of the museum, and wish peace to the troubled shade of its great founder.

#### A CORONER BROUGHT TO HIS SENSES.

At the sessions of Longford for December, 1852, Dr. Nicolls obtained a decree against one of the coroners of said county for £2 2s., a post-mortem fee, which sum the grand jury had disallowed, the barrister, Thomas O'Hagan, Esq., Q.C., holding that the 30th section of the coroners' act made it obligatory on the grand jury to present such sum as would reimburse the coroner.

Well done, Dr. Nicolls. If every one acted in this way, we should have less to complain of.

#### TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—I perceive a letter in your last week's publication, suggesting the propriety of a meeting of the medical officers of each union to appoint a deputy to represent them at the general meeting of the Dispensary Surgeons to be held in Dublin next month. I would suggest instead, that the Secretary of each County Medical Association should summon a meeting, when resolutions should be passed expressive of the wishes of its members, and a person or persons appointed to represent them at the general meeting.—Your obedient servant,

JOSEPH ROBINSON, M.D., &c.

Ballibay, January 8, 1853.

#### THE FEVER HOSPITALS IN CONNEXION WITH POOR-LAW RELIEF.

“The committee of the Roscrea Fever Hospital propose that all patients chargeable upon the poor-rates be henceforth admitted into the fever hospital at the rate of five pence per head per day, which charge shall include all expenses. They are desirous that this proposition should be acceded to for the following, amongst many, reasons:—

1. If the poor-law guardians determine upon building a fever hospital in connexion with the poorhouse, it will be attended with an increase of the rates—the result of the necessity of an immediate outlay; which, having a fever hospital already in operation, open for the reception of all patients at the low rate of five pence per day, would be naturally regarded by the majority of the ratepayers with feelings of dissatisfaction.

2. The erection of a fever hospital in the vicinity of the poorhouse, involving, as it must, some intercourse, however small, would hazard the extension of infectious fever amongst its inmates: this is to be greatly deprecated.

3. The committee of the Roscrea Fever Hospital are deeply anxious for its maintenance, because they are aware that there are those occasionally visited with fever who would never seek admittance into a hospital where they must sue as paupers; and yet, who in their small and crowded habitations, cannot receive adequate attention. In their experience, when one member of a family has been thus visited, and when the fever hospital (in some rare instances) has not been resorted to, the infection spreads, not only to the household, but, at times, to the neighbourhood, and the result is most disastrous. It is impossible to say, through the salutary check of the extension of infection through the instrumentality of the fever hospital, how many have been prevented becoming inmates of the poorhouse—how many have been preserved to labour or the support of their families, and it is impossible to say how

many, should the fever hospital be closed, may eventually come upon the rates. The committee cannot but look with gloomy anticipations upon the probable effects of the closing of such a valuable institution.

4. The committee of the Roscrea Fever Hospital are, many of them, large ratepayers, and are of course, equally with the guardians, anxious for the exercise of all due economy; and it is in this spirit that they submit, as a mutual advantage, the proposition referred to above, and which has been already adopted by the board of guardians of the Parsonstown Union—namely, to admit at the rate of five pence per head per day, this including all charges whatever, medical attendance, medicine, food, &c. Surely nothing can be more reasonable than this.

Should the guardians accede to this proposition, no outlay for building will then be required—no increase in the rates—no danger of infection to the inmates of the poorhouse. The admirable situation of the Roscrea Fever Hospital, it being completely isolated, prevents the possibility of infection being propagated. The admirable management of the hospital, is an assurance that all patients are carefully attended to; while an institution will be maintained, where those above the rank of paupers can find admission, either by payment, as in the case of policemen and others, or upon subscribers' tickets—to the saving of life in their own families, and to the prevention of the extension of fever in their neighbourhood.”

At a meeting of the Managing Committee of the Roscrea Fever Hospital, it was resolved that the following proposition be now submitted to the board of guardians by the committee of the fever hospital:—

“That patients chargeable upon the poor-rates be henceforth admitted into the Roscrea Fever Hospital at the rate of five pence per head per day, which charge shall include all expenses; and that the committee having carefully examined into a statement made at the board of guardians, relative to a person named John Cashen, No. in Register 587, admitted 9th May, 1852, having irregularly obtained admission into the fever hospital, not having been in fever at the time, but for the purpose of carrying on a courtship with one of the nurses, we find that such charge is perfectly unfounded, the person in question having been regularly admitted on the ticket of the relieving officer, and that it appears he had fever, and was regularly treated for it; and we consider that the case does not reflect the slightest discredit on the medical officers or others in charge of the fever hospital. Also, that we now (as we have always had reason to do) approve highly of the manner in which the affairs of the fever hospital are conducted by the medical officers.”

#### CHLOROFORM IN COLIC.

DR. ARAN of Paris, warmly recommends the internal administration of chloroform in repeated doses of from ten to twenty drops, in colic, and particularly in lead colic. He says, that it relieves the spasm more effectually than opium or belladonna, and moreover possesses the great advantage of being more safely repeated than either of these medicines. A hundred and fifty drops may, according to Aran, be given in twenty-four hours; and we have no doubt that even a larger quantity, though seldom required, may be safely administered, as chloroform is very quickly eliminated from the system. In corroboration of the value of chloroform in colic, the writer of these lines adds his experience of its efficacy in his own case. He had suffered the most excruciating pain in the back and abdomen for twenty-two hours, accompanied by incessant vomiting, which opium and hydrocyanic acid failed to mitigate: indeed, they were rejected as soon as taken. A dose of twenty drops of chloroform was then taken, well mixed in a little water. After this, there was no more sickness, and almost instantaneously the pain began to abate, and in ten minutes had entirely subsided. Upon a return of the pain, some hours afterwards, it was again and finally removed by a smaller dose of chloroform. The necessary purgatives were afterwards easily retained, and the cure completed.—*Association Medical Journal.*

# AMERICAN NOTIONS OF THE DENTAL EXHIBITION AT THE WORLD'S FAIR.

THE English metropolis has again resumed its usual business-like appearance, and its inhabitants have betaken themselves to their accustomed avocations; they are no longer jostled and hustled by the *staring*, fat-faced, merry-looking thousands of agriculturists from the provinces, or questioned by foreigners with strange physiognomies, and still stranger costumes; in fact, Mr. John Bull has London to himself again, and merely looks upon the present state of the exhibition as the remains of its former greatness, and as no inapt type of what we are informed the New Zealand traveller will one day behold when, standing upon an arch of London Bridge, he surveys the ruins of St. Paul's. It is not, however, to the New Zealand traveller, or the present state of the Crystal Palace, or the thousands of complaints of the different exhibitors in the different sections, to which we wish to direct the notice of our readers. The various branches of the arts and sciences, have doubtless their own periodicals, by means of which their wrongs can be brought before the public. Our duty is to direct the attention of our profession to the jurors appointed as judges in section X, in the great exhibition, a portion of which, may be fairly said, represents our profession. The gentlemen appointed to preside over this portion of the exhibition, were not, from the nature of their calling and education upon such matters, calculated to estimate rightly the various dental mechanism, dental appliances, porcelain work, &c., submitted to their inspection; and even had they sought an explanation from the exhibitors themselves (which they did not), we have no hesitation in saying, they could not, by any possibility, possess the requisite competency to arrive at a just conclusion so as to form a correct judgment as to the scientific construction and applicability of the articles submitted. We presume, therefore, the jurors discovered their own incompetency in this department of the section, and therefore contented themselves with the mere inspection and the awarding of prizes for the best collection of physicians', surgeons', aurists', and oculists' instruments and mechanical arrangements, which, to do the instrument-makers justice, had taken special pains to display to a *trading* and attractive advantage, by exhibiting their wares in immense show cases. Amongst the whole of this collection, for which prizes were awarded, we may safely assert there was not one (excepting the dental instrument-makers) which could be fairly termed modern instruments, used by dental practitioners. Yet these wise-acre professionals, who had so unceremoniously accepted this important office, as unceremoniously *dismisses* the whole batch of dental exhibitors, whose contributions, as we before observed, they could not, by education or practice, properly appreciate, as a poor-law relieving officer despatches the applicants from his office without a thought or consideration. Surely the dental practitioners of Europe will know how to appreciate the feelings of these *remarkable* jurors who hold their profession in such high consideration.—*Amer. Jr. of Den. Sci.*

## NEWSPAPER FOR THE FARMING AND GARDENING INTEREST.

January 1, will be published, price Sixpence, free by post, each volume complete in itself,

Enlarged to twenty-four folio pages,

The First Number for 1853, of the

## GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE;

A Weekly Record of Rural Economy and General News.  
The Horticultural Part Edited by Professor Lindley.

The Farming Part (under the Editorship of a Practical Farmer) treats of—

The Practice of Agriculture,	Management of Stock,
Agricultural Science,	Veterinary Science,
Animal and Vegetable Physiology,	Drainage,
Improvements in Implements,	Irrigation,
described by Woodcuts whenever requisite,	Forestry,
Better modes of Husbandry,	Road-making,
Results of Experimental Farming,	Farm-buildings,
Growth and Rotation of Crops,	Labourers,
	Treatment of Poultry,
	Agricultural Publications.

In short, whatever affects the beneficial employment of Capital in Land.

Reports are regularly given of the English, Scotch, and Irish Agricultural Societies and Farmers' Clubs—London Market Prices of Corn, Hay, Cattle, Seeds, Hops, Potatoes, Wool, Coal, Timber, Bark, &c., and the Weekly Averages.

As regards the Gardening Part (under the Editorship of Dr. Lindley), the principle is to make it a weekly record of everything that bears upon Horticulture, Floriculture, Arboriculture, or Garden Botany, and such Natural History as has a relation to Gardening, with Notices and Criticisms of all works on such subjects. Connected with this part are

## Weekly Calendars of Gardening Operations,

Given in detail, and adapted to the objects of persons in every station of life; so that the cottager with a few rods of ground before his door, the amateur who has only a greenhouse, and the manager of extensive gardens, are alike informed of the routine of operations which the varying seasons render necessary. It moreover contains Reports of Horticultural Exhibitions and Proceedings—Notices of Novelties and Improvements—in fact, everything that can tend to advance the profession, benefit the condition of the workman, or conduce to the pleasure of his employer; Woodcuts are given whenever the matter treated of requires that mode of illustration.

Replies to Questions connected with the object of the Paper are also furnished weekly.

Lastly, that description of Domestic and Political News is introduced which is usually found in a Weekly Newspaper. It is unnecessary to dwell on this head further than to say, that the Proprietors do not range themselves under the banners of any Party; their earnest endeavours are to make the *Gardeners' Chronicle and Agricultural Gazette* a full and comprehensive record of facts only—a Newspaper in the true sense of the word—leaving the reader to form his own opinions; their object being the elucidation of the Laws of Nature, not of Man. The reader is thus furnished, in addition to the peculiar features of the Journal, with such information concerning the events of the day, as supersedes the necessity of his providing himself with any other weekly paper.

A Prospectus, with List of Contributors, may be had on application, or by letter, at the Office, 5, Upper Wellington-street, Covent Garden, London.

Parties intending to commence with the New Volume had better give their orders at once to any Newsvender.

**QUEEN'S UNIVERSITY IN IRELAND.**

As part of the qualification for Examination for Medical Degrees, the Senate recognize the Certificates of the Medical Lecturers in the various Universities and Chartered Institutions of the United Kingdom, and also of the Lecturers in certain Medical Schools and Hospitals, which, having applied for recognition, have shown their fitness for it.

But it is to be observed, that by the Medical Ordinance of the Queen's University, which came into force on the 1st of October last, it is strictly required that all recognized Lecturers and Clinical Lecturers, without exception, shall furnish to the Secretary of the University a Return, in a prescribed form, of the Students attending their Lectures, otherwise their Certificates will not be received. Students who purport to present themselves for Examination for Medical Degrees in the Queen's University, should therefore ascertain that their names are thus returned for any Medical Lectures they may attend, lest in consequence of such returns not having been supplied, their qualifications should be deemed insufficient when they so present themselves; and Lecturers who are willing to make the required Returns, and who have not received the necessary forms through the Registrars of the respective Institutions, should cause application to be made for them.

ROBERT BALL, LL.D., Secretary,  
The Queen's University, Dublin Castle.

**TO THE MEDICAL PROFESSION AND THE PUBLIC.**

GEORGE OLDHAM AND CO.,

**APOTHECARIES AND CHEMISTS,**

in availing themselves of the present opportunity to return their grateful acknowledgments to their Friends for the support which they have hitherto received, and which they will regard as a fresh motive for exertion, beg leave to announce that they have taken the

ROYAL MEDICAL HALL, 64, DAME-STREET,  
(Late Bewley, Owen, and Co.'s.)

which they will henceforward conduct in connexion with their  
MEDICAL HALL, 107, GRAFTON-STREET.

In notifying the above change in the management of the Royal Medical Hall, G. O. and Co. can assure the present Friends of that establishment, that the same scrupulous attention and care has been paid to the selection and preparation of their Medicines and other articles, which has gained them such extensive support in their Medical Hall, 107, Grafton-street; and they hope their arrangements to ensure accuracy, neatness, and despatch, combined with moderation of charges, will merit the approbation of those who may entrust them with their commands.

The Royal Shaving Cream, Essence of Ginger, Matice, Tooth Powder, Essence of Rhubarb, Ginger, and Chamomile; and other preparations heretofore made and sold at the Royal Medical Hall, can now be had at either Establishment.

107, GRAFTON-STREET,

AND

64, DAME-STREET, DUBLIN.

**TO SURGEONS, DISPENSING CHEMISTS, ETC.**

SULPHATE OF QUININE, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, capsuled, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.  
October 23, 1852.

**DR. JACOB ON DISEASES OF THE EYE.**

Just published, 8vo, pp. 96, price 2s. 6d.,

**A TREATISE ON CATARACT;**

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F.R.C.S.,  
Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5s.,

### AN EXAMINATION OF THE MEDICAL FACTS IN THE CASE OF THE QUEEN v. KIRWAN: WITH MEDICO-LEGAL OBSERVATIONS.

By T. G. GEOGHEGAN, M.D.,  
Fellow and Professor, Royal College of Surgeons, Ireland,  
Surgeon to the City of Dublin Hospital,  
Member of Council of the Surgical Society, &c. &c.

THE extraordinary interest which has attached to the late trial of William Burke Kirwan for the murder of his wife, has been sufficiently evinced by the protracted discussion of the subject in the public prints. What may have been the qualifications of the persons who have engaged in the controversy, it is no part of my purpose to inquire; nor shall I comment on the dangerous consequences which are apprehended, if, in future, solemnly and deliberately conducted judicial inquiries, should become subject to the revision of popular clamour. These topics have been of late handled with much force by those whose province it is to discuss them. I have been induced to attempt an exposition of the medical facts, both in consequence of my having observed that the majority of the profession appear to be, and (for obvious reasons) necessarily *must* be, but imperfectly acquainted with them; and also as the inferences to which they lead, appear of considerable moment in a medico-legal point of view. Some of the conditions noticed on the body seem also not to have attracted the attention which their peculiar nature and importance demand.

Having been consulted by the crown at an early stage of the case, and having been present during the entire trial, I have had the opportunity of becoming fully acquainted with its medical relations. I shall, in the first instance, state the medical facts, both as they appeared in evidence, and as elicited by the crown previous to the trial. It will, however, be necessary to premise such observations on the locality in which the death occurred, and also on the general facts, as may render the medico-legal details more clearly intelligible.

Ireland's Eye is a small and at present uninhabited island, situate about a mile to the north of Howth, and from its picturesque character, frequented chiefly by par-

ties of pleasure. Towards its south-eastern end, looking seaward and N.N.E. and S.S.W., is an inlet, the "Long Hole," about 360 feet in length, narrow at its entrance, and much wider towards its head. A little beyond its middle (proceeding from the sea), it is divided into two channels by a large and elevated rock. The head of the Long Hole is defined to the observer at Howth by a narrow quadrilateral chasm, formed by the termination of the precipitous cliffs which bound it on either side, and is distant from the nearest part of Howth harbour about 1250 yards in a direct line.

Towards the sea, the bottom of the inlet is rocky, and landward, is formed of coarse gravel. 150 feet from its head, a low barrier of rocks stretches across the channel, about twelve feet above low water-mark, the channel at this part being twenty-eight feet in breadth. Just within this barrier, and immediately at the base of the south-eastern wall of the inlet (which is here thirty-one feet high), the body was discovered a little before nine p.m. It lay on the back, in a direction parallel to the course of the channel. The head, placed towards the sea, hung backwards, resting at the base of one of the barrier rocks (three feet in height). The body lay on a low rock (nine inches high), the arms were extended, the knees bent, and the feet lay in a small pool of water. A little below the feet was another rock, sixteen inches in height. These rocks were covered partially with seaweed and scattered limpets. The deceased was found clad in a wet bathing dress with loose collar, and bathing boots. The former was "gathered up towards the arms." A wet sheet lay beneath the body. The head was uncovered, and the hair filled with seaweed and gravel. The bathing cap was discovered at high water-mark a few days afterwards. The clothes of deceased, the situation of which was pointed out by the prisoner, were found at an elevation of five feet and a half on a steep part of the large rock, already described as dividing the channel, and at a distance of seventy-two feet from the body. From the place the clothes occupied to the "body-rock," the bottom of the Long Hole declines towards the sea by a gradient of about one in eighteen feet.

It appeared from the concurrent testimony of five witnesses (one on sea) that several screams\* were heard to proceed from the direction of the island at seven p.m., at which time, according to the carefully checked measurements of the surveyor, Mr. Jones, there was a depth of but twenty-one inches of water over the "body-rock," and a total depth of thirty inches beside it. The water's edge at this time was about sixty feet beyond the "body-rock," and sixteen feet below the spot occupied by the clothes.† The tide was receding, the water and the weather perfectly calm.

When discovered, the body was warm and flexible, and presented other conditions, to be afterwards described. Having been wrapped in a sail, it was conveyed to Howth at midnight, at which time the limbs were still pliable, but the surface cold. It was washed shortly afterwards by the peremptory direction of the prisoner, despite of the remonstrance of one of the assistants, who suggested that it should be first inspected by the police. The recent external appearances were observed by an experienced nursetender, who had lived at Howth forty years, and who had, during that time, externally examined numerous drowned bodies, and was in the habit of laying out the dead. They were also witnessed, for the most part, by the boatman who discovered the deceased's body, and by the assisting women.

They were as follows: Intense and dark livor of the right side, extending from the axilla to below the knee. Eyes much injected; the right one closed, left open. Considerable swelling of the lips, especially the upper. Thin white froth about the mouth‡ and nose, recurring in quantity after removal, and still observable on the second day, at which time the body was free from putrefaction. The eyelids were livid, but unswollen.§ The belly flat. Blood flowed freely from the ear-passages for a considerable time (notwithstanding repeated cleansing with the corner of a towel). Blood also flowed rather freely from the genitals (and was found by the nurse in coagula on the sheet when deceased was about to be placed in the coffin); "it was not like the natural discharge, but thick and black."

There were superficial cuts or scratches on the eyelids, cheek, forehead, and right temple, and blood is stated to have flowed from the left nipple (from a scratch?), all of which were still bleeding freely while the body was being washed. The edges of the ears were rubbed, and the lobe of right nearly detached. The nose was crooked, the neck "a little twisted," but otherwise showing nothing unusual.

In addition to the above, the following conditions (not elicited in evidence) had been ascertained: Lividity of the face; bluish blackness of lips and nails; considerable swelling of the external genitals.||

A coroner's inquest was held, and although no post-mortem examination had been instituted, and notwithstanding that the general facts were of a character to awaken strong suspicion, a verdict of accidental death was returned.

The attention of the authorities having been subsequently

\* By one witness they were stated to have been those of a female.

† Having been present during Mr. Jones's measurements on October 20th, I can testify to the great care with which they were made. A writer who has taken general exceptions to Mr. Jones's calculation of the tide, admits notwithstanding, that at the above hour, the assigned depth at the "body-rock" was, as nearly as possible, correct. High water on September 6th, was at half-past three p.m.

‡ Froth was seen on the mouth when the body was found, also when the body was washed, "white foam streaming up from between the closed teeth." (Magar.) On the second day (Mr. Hamilton) "a good deal of froth about the mouth, thin, white, and stationary." The neck and shoulders and the abdomen were at this time rigid.

§ "As if from putrefaction" (Mr. Hamilton). As rigor mortis was then in existence, this view is evidently incorrect. The lividity was seen on the first evening by the nursetender.

|| This condition (observed in the deceased by the nursetender) has not escaped the notice of the Germans. Meckel (Lehrbuch der Gerichtlichen Medicin) says, "Unter letzteren sind am auffallendsten die blutaden der äussern und innern geschlechtstheile angeschwollen, wodurch blutunterlaufungen (z.b., in scroto und in den labiis pudendi) bewirkt werden."

directed to the case, an exhumation was ordered, and took place on the 6th of October, thirty-one days after death,\* and twenty-six after burial, the mean temperature of the interval having been 55 deg. The post-mortem examination was carefully performed by Dr. Hatchell, F.R.C.S., to whom I am indebted for the following account:—The body had been buried at a depth of about seven feet; the grave was found to contain much water, which had freely penetrated the interior coffin. The surface of the body presented the appearances of one that had been at least partially surrounded by water. The face covered with a greenish film of soapy consistence. The right eye was prominent, and the left protruded on the cheek. The conjunctival vessels of both were much injected. The upper lip was swollen. The tongue projected between the teeth, and was marked by the latter. The lining membrane of the mouth and gums was livid. The abdomen was much distended with gas. The labia pudendi were livid, very much swollen, and everted, but not emphysematous; their inner surface very vascular. The whole of the right side, from the axilla to the knee, was of a purple red colour. There were no signs of injury on or beneath the scalp. The margins of both ears were scratched, and the lobe of right ear was wanting. There were also scratches above right eyebrow and over right malar bone. The neck was greenish, but presented no marks of ecchymosis or abrasion.

Interior: Dura mater flaccid. Brain semi-fluid and of a pink colour. No trace of fracture or extravasation. There was nothing remarkable either in mouth, larynx, or pharynx. The lungs were collapsed and greatly engorged with blood\* at the posterior, inferior, and lower part of anterior surface, but otherwise healthy. The bronchial tubes were empty. The heart was quite healthy, and its cavities and the adjacent veins were empty. The diaphragm was pushed high into the chest by the pressure of gases in the intestines. The stomach was empty and contracted. Urinary bladder in a similar state. The uterus was small, and its cavity contained no bloody or other fluid. An ulcer covered with yellow pus was observed in the os uteri, extending into the cervix. Ovaries small and flattened. The vagina was purplish, much congested,

\* The mode in which in this country medico-legal investigations are usually conducted under the system of coroners' inquisition, is too often such as to render the procedure nearly an useless, if not a ludicrous, formality. This is not so much to be laid to the charge of coroners individually, as to the system which denies to the important office a just remuneration. Grand juries also, in the exercise of an unwise and paltry economy, too often indirectly influence the coroner to withhold the necessary medical investigation. The difficulties, however, on the latter head, have been, in some degree, diminished by one of our city members (Mr. Grogan, who, in his "Coroners' (Ireland) Bill," has introduced a clause which refuses remuneration, in numerous cases, to the medical witness for his laborious services. The preliminary judicial inquiries in Germany afford a startling contrast to our own. There, inspection is conducted in the presence of both medical and legal functionaries. The former are the physician or judicial physician, and the kreis-chirurgus or district surgeon. The legal, are the investigating magistrate, the actuary, and the assessors. Under such auspices, it may be assumed that the investigation will be conducted with rigorous precision. All the cavities are carefully and systematically examined, and on the inspection being completed, the physician draws out his report (visum repertum), to which he is to attach his medical judgment on the case (gutachten elogium). On the legal side a report is also furnished (obductions-protocol), which, in addition to the general facts, gives the result of the inspection and the medical judgment.

† Dr. Hatchell, who is well known as an experienced anatomist, and has had a large experience in medico-legal inspections, stated at the trial that the amount of congestion observed was greater than any he had ever seen in simple drowning. The amount of congestion, although *per se* insufficient to furnish a criterion between simple and complicated drowning, or between drowning and other forms of asphyxia, was unquestionably of weight as part of the entire series of medical facts.

and its mucous membrane smeared with a thin bloody fluid. The genital organs presented no trace of wounding. Rectum natural. The blood was generally fluid, and flowed copiously on division of the great veins of the neck, and from the superior cava. The cavities of chest and abdomen showed scarcely any traces of decay.

It appeared that the deceased had been seen late on the day of the fatal occurrence, apparently quite well, walking and reading on the island. The woman with whom she lodged considered her to be in good health; and that she really was so, is rendered further highly probable by the circumstance, that during her stay at Howth she was known as a most adventurous swimmer. No evidence was adduced at the trial to show that she had been the subject of any previous disease, and the prisoner, on examination at the inquest, made no allusion whatever to the subject. An attempt, it is true, was made, through one of the witnesses, to establish that she had an hereditary predisposition to epilepsy; this was coupled, however, with the admission that the information was derived from a deeply interested party. This same matter of hereditary tendency is also alluded to in a singular document bearing the signatures of Dublin practitioners, privately circulated in Dublin, and afterwards published in a London paper.

The document alluded to, if genuine, would lead to the conclusion, that the subscribers believe, that a certificate, which they *do not profess to have seen*, and to the effect that a certain person "*died of a fit*" (the kind not stated), is to be received as evidence that his daughter perished by epileptic drowning! Another less refined species of evidence, however, was thought desirable; accordingly, two witnesses (an *artist and a servant maid*) some time after the trial make declaration (not oath, as erroneously stated by the subscribers of the above document), that the deceased had been seen by them on two occasions in a fit, and that the *prisoner was present*. On this evidence every person of common sense may be left to form his own conclusions. It would be drawing too largely on human credulity to demand the belief, that prisoner's counsel or his experienced solicitor should not have been aware of these *facts* (?), nor of the above witnesses having been in attendance; nor, again, of the views of the medical witness who entertained the epileptic theory of death, and who was present and in communication with counsel on both days of the trial. How far the admission of their truth should have influenced a decision on the cause of death, we shall presently consider.

The medical facts, the import of which we are about to examine, are of a three-fold kind—first, the important external conditions noticed by the several persons while the body was still quite recent; secondly, those observed at the post-mortem examination; and lastly, and in connexion with the two preceding, the medical history of the deceased, and such collateral circumstances as are closely interwoven with the medical data, and appreciable in their true relations by the medical inquirer only.\*

\* It may be desirable here to examine a question on which much misapprehension prevails; I allude to the influence which putrefaction exerts both on the morbid condition of internal organs and on the external signs of violence. In the document to which I have already alluded, and in one appended to it, and which, as bearing a solitary signature, is, I presume, considered a *cheval de bataille* by the prisoner's friends, the doctrine is maintained that a month's (in reality twenty-six days') interment in a moist place renders it impossible to determine the existence of morbid changes or signs of violence. This statement is not only refuted by the dissection, in which some of the external signs of congestion and of violence were found to have remained unaltered, but is opposed by the experience of Orfila, the highest authority on legal medicine. Of the brain, he writes: "*Pendant plusieurs semaines, à moins que la température n'ait été fort élevée le cerveau conserve assez toutes ses propriétés normales pour qu'on puisse y reconnaître les diverses parties que entrent dans sa composition et constater les traces des épanchemens, cependant il tend de bonne heure à devenir d'un gris olivâtre clair.*" From the latter fact, the inference that the brain was congested at the time of death appears to have been a sound one.

In the case which forms the subject of this communication, a careful consideration of the *entire series of appear-*

Of the lungs, Orfila says:—"Ils conservent leur aspect naturel pendant long-temps; on peut même au bout de *quelques mois* reconnaître leur structure, et constater s'ils sont le siège d'une lésion pathologique." In a body, the exhumation of which I superintended at Mount Jerome, by direction of Government, and which had been three weeks buried in a *very wet grave*, I had no difficulty in determining the cause of death, or in recognizing the conditions of the thoracic and abdominal viscera. In conjunction, also, with Dr. Hatchell, I lately examined two cases after a month's interment, under similar conditions. The inner organs had undergone, remarkably, little change. The chief alterations in such instances arise from the accumulation of gases in the abdomen, and the influence thus exerted through the diaphragm on the right side of the heart. There are other interesting effects of gaseous accumulation which seem generally little understood, but of much moment in practice. One of these is the protrusion of the eyeballs, which occurs in putrefaction under water, or in *rapid* putrefaction in the air, and which was witnessed in the present case. In a celebrated criminal trial here in 1842 (the *Queen v. Byrne*), I stated and (still more to the point) *proved*, the occurrence of such a condition; which depends, as I have found by dissection, on the accumulation of gases in the back of the orbit. As protrusion is the opposite condition to that observed in the slow putrefaction of the dissecting-room (where transudation of the fluids of the eye more than keeps pace with gaseous development), my statement was received with incredulity by that portion of the profession which, inexperienced in medico-legal questions, assumes, notwithstanding, on *important occasions*, an almost *exclusive right* of deciding on them. My view on the subject, in the trial alluded to, was fully concurred in by a gentleman (Mr. Robert Adams) as well known to surgical science as he is respected for his sterling integrity and worth. Protrusion of the tongue may be similarly produced. The second effect of gaseous accumulation is, the expulsion of the contents of the stomach and rectum; and hence the presence of portions of food in the mouth, fauces, and air-passages in persons who have lain some time in the water. The absence of food in these quarters in Mrs. Kirwan's body, and the contracted state of the stomach, clearly prove that the organ was empty at the time of death. Dr. Hatchell and myself have found by experiment that the saline ingredients of seawater are not sufficient to prevent the expulsion of the latter from the stomach by gas-pressure in the abdomen. As respects the influence of putrefaction on congestion of the lungs, it is certain, alike as a matter of fact and theory, that the latter condition cannot be *produced* by decomposition. It is true, as Orfila remarks, that congestions which, in the recent lung, under the influence of gravity, occupy the most depending parts, become more diffused when decay takes place. But in such cases the nature of the congestion must be determined, as in that of recent origin, by the amount of the accumulation and by collateral facts. Exclusive weight is too often attributed to the influence of time and other extrinsic circumstances on the putrefactive process. The *intrinsic* conditions of the body, though more obscure, often exert a much greater effect. Thus, I have seen a body, thirty-six hours after death, in cold weather, in a state of extreme decomposition, with enormous extrication of gas. The influence of decomposition on the blood is also much misunderstood. If coagulated at the time of death, it remains so, often for several weeks. The fact to which, I believe, Bernt first drew attention (*Beitrag zur Gerichtl. Medicin*, ii., 231), that the condition of the blood, as to fluidity and coagulation, varies in the *same body*, is often overlooked. Thus, in the *venæ innominatæ*, spinal and cerebral veins, it is often fluid while coagulated in the heart. I have constantly observed that it differs in these respects in the heart and lungs, and even in the auricles and ventricles of the heart. When the heart is empty in a body in which the abdomen is distended with gas (if the organ were not empty at the time of death), the blood may be assumed to have been fluid at that period. I have found firm coagula in the heart after three weeks' interment in wet ground. Another circumstance deserving of notice is the coagulation of extravasated blood in cases where it remains fluid in the vessels. Thus, I have sometimes observed the blood which has flowed in a fluid state from drowned and other bodies to coagulate by exposure. Dr. Monro observed the same in hanged persons.

ances, taken in connexion with the fact, that the deceased had been immediately before in good health, that the body presented no sign of organic disease capable of suddenly terminating life, nor of other modes of violent death (as wounding, &c. &c.), clearly proves that the fatal event was the result of asphyxia. Thus, under the circumstances above described, there were present, intense congestion of the otherwise healthy lungs, dark and fluid condition of the blood,\* intense livor of the dependent parts of the surface. To these were superadded the signs which are present, where suffocation is the result of incomplete exclusion of air, and consequently protracted struggle—namely, froth about the mouth and nostrils, injection of the eyes, and considerable swelling of the lips, and lastly, those local hæmorrhages which sometimes occur where asphyxia has been combined with compression of the neck or chest. The defence adopted by the prisoner's counsel, based on the views of one of the medical witnesses, was, that the deceased had been seized with epilepsy while bathing, shortly after a meal, and had thus been drowned in shallow water. No attempt was made to show that she had perished either from epilepsy alone or from apoplexy. Independently of other considerations, the latter view might have been refuted, simply by reference to the situation of the body when discovered; for had deceased been attacked by either on the shore, or where the water was so shallow as not to have covered the mouth and nostrils, the body could not have been afterwards wafted to the "body-rock" by the receding tide, even had it (in the absence of any assisting cause) presented the unusual condition of buoyancy immediately after death.

The phenomena of drowning present themselves practically under two distinct forms—1st, where the submersion is continuous from its commencement, and where asphyxia is consequently produced in its most rapid form; 2ndly, where the drowning person, in possession of consciousness and volition, maintains a more or less protracted struggle, rising and sinking for some time beneath the surface of the water. A corresponding and marked contrast exists in the appearances of each. In the former, the face is pale and placid, lips unswollen, and froth is absent from the mouth. Internally, the signs of congestion are comparatively slight, and not unusually altogether wanting. Such are the results of numerous practical investigations on the subject by the most eminent medical jurists.† Several very careful observations and dissections of the drowned, have led me to the

\* The intensity of the livor of the right side of the body, the colour of the blood discharged from the genitals, and the persistent bleeding of the superficial wounds, sufficiently attest the above character of the blood. The empty condition of the heart also afforded a presumption to the same effect; for I have found that when the organ contains coagula, these are not expelled by the pressure of gases in the belly. It must, however, be remembered, that in some cases of asphyxia, in which the lungs were much congested, the heart has been found altogether empty (as in the celebrated case of the Prince de Conde, who hanged himself during the revolution of 1830 (Examen. Med. Leg. de Causes de la Mort de S. A. R. le Prince, &c., Ann. d'Hygiène, tome v.); and in some of Devergie and Orfila's careful dissections, the left heart contained more blood than the right. Such exceptional conditions, however, would be likely to be mistaken only by those who fall into the error too common in medico-legal inquiries, of forming a judgment from individual and not from the combined appearances and medical facts. In Mrs. Kirwan's case, the recent condition of the heart is unknown. The very free flow of blood, however, on section of the great veins at the base of the neck, renders it probable that the right auricle was loaded. Any objection to the evidence of asphyxial death, on the above score, applies with equal force to the epileptic theory of death. In the case of Ferrari (London, 1831), the heart was quite empty and the lungs not congested. Here the death, according to the confession of the prisoner, was by smothering. The characters of the body were chiefly negative. The organs generally were healthy. The conviction was had entirely on circumstantial evidence.

† Vide Orfila, *Traité de Med. Leg.*, Piorry's Experiments, Watson's *Med. Leg.*, Treatise on Homicide, p. 150, et seq.

same conclusion. It is almost superfluous to observe, that the epileptic, who falls helpless and senseless in the water, is placed in the former of the above-named conditions. Hence the ordinary phenomena of epilepsy (out of the water), which depend on partial closure of the aperture of the windpipe and prolonged expiratory effort,\* are at once superseded by those of rapid drowning. A good illustration is afforded by the following case, for an opportunity of examining which, I am indebted to my friend Dr. McDowell:—A lunatic female, subject to a modified epilepsy (epilepsia silens), was found dead and lying on her back in a trough, in which she had been in the habit of washing, and the water in which was about eighteen inches deep. The face was pale and perfectly calm, like that of a person in sleep. There was no froth at the mouth, injection of the eyes, or swelling of the lips. The lungs were but slightly congested.† A few trivial contusions existed on the posterior part of the body.

The appearances of the countenance and those of the lungs, in the Kirwan case, were therefore altogether opposed to those of epileptic drowning.†

The previous history of deceased (as we have already seen), the posture of the body as compared with the external marks of injury, and the absence of any exciting cause, were alike in conflict with the above hypothesis. Had the deceased been seized with epilepsy, and fallen on her face, she would have remained so, as the convulsive motions (either of the disease or those of drowning) could not have sufficed to have turned a body which the presence of scratches would indicate to have lain in contact with the subjacent rock.§ Had she, on the contrary, fallen on her back, there should have been no scratches on the face. Lastly, the assumed exciting cause did not exist. The stomach, on dissection, was found empty and contracted. From the latter circumstance, it is manifest, on the grounds already stated, that, at the time of death,|| the organ contained no food. The discussions relative to epileptic screaming, were alike superfluous and absurd, inasmuch as screams could not be repeated by a person lying, as was assumed, with the mouth under water, and as on the occurrence of the fit the sufferer falls at once. Had those appearances alone, which have been already considered, been

\* See Marshall Hall on Epilepsy, *Lancet*, 1852, and *Medico-Chirurgical Review*, vol. xxv.

† A person who falls insensible into the water from any other cause, presents the like appearances. A year since I inspected the body of a man who was drowned by falling on his face in a shallow ditch in a fit of deep intoxication. His face was slightly scratched and bleeding, but otherwise natural; no froth or swelling.

‡ Fodere (*Traité de Med. Leg.*) notices the absence of froth in epileptic drowning. Dr. Ogston's experience, as he informs me, is the same. In some cases, the prolonged expiratory effort and subsequent reaction of the walls of the chest, gives rise to the entrance of mud or gravel into the respiratory passages in epileptics drowned in shallow rivers or pools. If the water be so shallow as not completely to cover the mouth and nostrils, the appearances are those of more protracted drowning. In some instances, persons falling intoxicated into the water, struggle instinctively for a time. Were this to occur in shallow water, the same instinctive struggles (prompted as they are by sensation) would probably enable the sufferers to escape. In epilepsy, however, the insensibility is complete.

§ An attempt was made to show that the marks were produced by crabs. This is refuted both by the character of the injuries, by the evidence of the nursetender who, from long observation of drowned bodies, was familiar with such, and also by the fact that no crabs were discovered about the body, with which they must have been very busy in order to have produced the injuries observed so soon after death.

|| The *Standard* newspaper has invoked the assistance of Juvenal and Persius in aid of the theory of epilepsy after dinner. Had these sharp-witted poets undertaken, in default of other assistance, a judicial inspection of the Roman matron, and failed to find some remnants of the peacock, they would scarcely have ventured on the above explanation. This, however, is the age of invention!

present, it is evident, from preceding facts, that the deceased, *if drowned at all*, must, during no inconsiderable period of the process, have been in possession of consciousness and voluntary motion. Suicide by drowning in shallow water being out of the question, both from the medical and general circumstances,\* the question, therefore, would then have presented itself for the jury—By *what obstacle* the escape of deceased from shallow water had been prevented?† An answer to this might perhaps, without difficulty, have been found in the moral facts. The question, however, must now be entertained—Was *drowning at all concerned* in the production of the fatal result? The post-mortem conditions, taken in their integrity,‡ were, in my judgment, incompatible with drowning in its simple forms; for, after a careful and extended examination of the subject, I have been unable to discover a *single case*, amongst the numerous instances of drowning on record, in which bleeding either from the ears or genitals (independently of wounding), has been noticed, or even any general statement to the same effect. I have been equally unsuccessful, in the inquiries which I have instituted amongst those most competent, from medico-legal experience, to elucidate the subject. One of the city coroners informs me that, out of about 270 cases of drowning that have fallen under his notice, nothing of the kind has been observed.§ Dr. Ogston of Aberdeen, whose admirable practical researches on drowning are well known, informs me that he *has never* met such hæmorrhages in that form of death. Exclusive of the bleeding

\* The cases related in some modern works of suicidal drowning in shallow water (unfrozen on the surface), do not appear to be substantiated by sufficient evidence. The occurrence, however, is perhaps not impossible. In such a case, the conditions of the countenance, &c., should manifestly be those of *continuous* submersion, as already described.

† I can state, from very minute examination of the Long Hole, that none existed in the nature of the bottom.

‡ The Dublin medical dictum is not only in conflict with the well-ascertained facts of legal medicine (to which I have already adverted), but also ignores or *eludes* the circumstance, that the decision of juries in questions of homicide, is based not merely on the *medical evidence*, but on the *entire body of facts* submitted to them. Were this not so, the functions of the jury would virtually cease. Daily experience shows that in cases where two or more hypotheses as to the cause of death are left open by the medical witness, a jury may determine from the general evidence which is the true one.

§ From equally careful inquiries, I arrive at the same result with regard to epilepsy. Dr. Wade of Belturbet, has indeed favoured me with an instance, in which a person, seized with epileptic convulsions, was found to have been "*deluged with blood*," which had flowed from the vagina. Dr. W., however, candidly admits, that he is not aware whether the bleeding preceded the convulsions. The copiousness of the discharge renders it probable that the case was one of flooding, followed by the usual cerebral symptoms attendant on hæmorrhage. My venerated friend, Dr. Marshall Hall, known throughout the world as a profound physician and physiologist, and who has devoted, as is well known, especial attention to epilepsy, has favoured me with a note to the following effect:—"MY DEAR SIR,—I have never seen bleeding from the ears or vagina in epilepsy. Bleeding from both ears and vagina occurs in hanging."\*\*\*\*\* I have received similar statements from other distinguished members of the profession—Drs. Alison, Christison, Ogston, and Bennett. Dr. D. MacLagan informs me of a case in which epilepsy was produced by the entrance of a foreign body into the ear, in which "the local determination should have favoured bleeding from the ears, if likely to occur, but nothing of the kind was observed." Bleeding from the ears is mentioned, in general terms, by one or two of the older French authors, but is unsubstantiated by the recital of a *single case*. This, therefore, is probably one of the "*false facts*" of earlier medicine. It reminds us of the consultation described (if I remember aright) in Tristram Shandy, in which the doctors decided, that a man who *did not* die of plethoria after amputation (according to theory) ought to have done so. Were bleeding from the above quarters even a usual result of epilepsy, this obviously could not have affected the question of *epileptic drowning*.

from the ears and genitals, the medical facts are obviously reconcilable, either with strangulation or the protracted form of drowning. Thus, the conditions of the countenance are common to both, as are also the state of the lungs, stomach, and blood.\*

The above hæmorrhages, however (occurring independently of mechanical injury), have only been observed in asphyxia resulting from either strangulation (including hanging) or compression of the chest. This subject appears not to have sufficiently attracted the attention of medical jurists; yet it would appear that vaginal bleeding has been frequently noticed in hanging and strangulation. Thus, Dr. Cooke has recorded three cases of suicidal hanging in lunatics† which have fallen under his own notice, and in two of which the subjects had passed the period of menstruation. It seems to have been frequently noticed in executed criminals; so much so, that, as Dr. Cooke and others state, it has been the practice in some prisons to place straw under the drop in female executions. I learn from a gentleman who was present at the dissection of Butterly and Ennis, hanged in this city some years ago, that he observed their drawers copiously stained with blood. This condition, which formed a subject of controversy some years since, has been described as menstruation. By whatever title, however, it is designated, it is equally important, if present as a consequence of strangulation, and not of other forms of asphyxia. In Mrs. Kirwan's case, that the discharge was neither the result of menstruation nor of wounding, was evident from the careful dissection performed by Dr. Hatchell.

No fluid of any kind was found in the uterus; the *healthy pus* covering the *ulcer of the cervix* was unstained. A thin, *bloody* fluid coated the walls of the vagina, which, with the interior of the labiæ, were highly congested. The blood discharged from the genitals was also observed by the nursetender in clots upon the sheet. Further, had the deceased been menstruating on the day of her death, it is most improbable that she would have bathed. Finally, the nature of the discharge is corroborated by the co-existence of bleeding from the ears. The latter condition has been noticed as an occasional occurrence in strangulation and hanging. It is to be expected in those cases only

\* Although froth was not discovered in the air-passages on dissection, it unquestionably existed there at the time of death. No other view can explain the abundance of recurrent froth while the body was still fresh. Thus, on the second day, notwithstanding the previous cleansings, it was present in abundance about the mouth (Hamilton). There appears no reason for refusing to the presence of asphyxial froth in the latter situation, the same weight which is attached to its existence in the windpipe, provided that its characters are equally well defined, and that it is supported by a consistent train of collateral appearances, and in harmony with the remainder of the medical facts. If an opposite view has gained some credence, it has been probably in consequence of the servility with which some of late have adopted the opinions of the French writers on legal medicine. I have also observed in the drowned, that movement of the body (by acting on the walls of the chest) causes the expulsion of the froth, so that while abundance has appeared about the mouth and nostrils, little was discovered in the windpipe. The same result arises from bodies being placed in warm rooms, from the occurrence of rigor mortis, and from the tympanitic distension of the belly, is sometimes observed in the drowned, while the body is absolutely fresh, and occasionally takes place in the *process* of drowning. Where the inspection is delayed, or where the body has lain in water, Orfila has shown (*Exhumation Juridiques*) that the froth of drowning is generally absent. As respects the condition of the stomach, this (contrary to the opinions current in medico-legal works) will not always suffice to distinguish strangulation from protracted drowning. In two cases of the latter I found abundance of froth in the air-passages and about the mouth, but *no water whatever in the stomach*; in epileptic drowning (also contrary to received notions), I have seen the converse of this in one instance. The absence of sea-water, therefore, from Mrs. Kirwan's stomach, furnishes no argument against the possibility of death by drowning.

† *Lancet*, 1830-31.

where, from a concurrence of favouring circumstances, the congestion is extreme.\* The source of the bleeding probably varies. Little found the membrana tympani ruptured in a case of manual strangulation;† but probably such a condition is by no means indispensable.‡ The occurrence of aural bleeding in strangulation and its absence in drowning, are, I conceive, readily explained. In the latter, the obstruction to the return of blood from the head is to be sought for in the loaded state of the right heart, and in the great impairment of the respiratory motions. In strangulation an additional source of obstruction is furnished by the pressure on the jugular veins, while the arteries continue to deliver blood to the head. In drowning, again, the entire tract of the venous system of the head and neck, and downwards to the heart, is open to receive the accumulating venous blood; while in strangulation all that portion below the seat of compression ceases to be so available. The occurrence of hæmorrhage from the vagina, in the latter form of death, does not admit of this explanation. It seems to be produced by the same conditions which occasionally give rise to bleeding into the cavity of the stomach, and to ecchymosis on the surface of the pancreas, sometimes observed in hanging.§ In what those conditions differ from those of drowning, is less clear. The fact of the absence of vaginal bleeding in drowning, and its not uncommon presence in hanging, is not the less incontestable. An analogous fact presents itself in the male subject, in the erection and seminal emission of the hanged—a phenomenon which obviously depends on accumulation of blood in the organ. Whether these conditions, however, arise alone from obstruction to the return of blood to the right side of the heart, or from the influence of congestion of the cerebellum, I am not prepared to state. The greater rapidity of death by drowning (*ceteris paribus*), as compared with strangulation, and which, according to Sir B. Brodie, is perhaps due to the concurrent influence of cold, may assist in explaining the differences in the amount of congestion and consequent hæmorrhage in the latter form of violence. The nature of the medium may also have its effect.

Bleeding from the ears also occurs in compression of the chest; thus it was observed in three out of twenty-three persons suffocated by pressure in a crowd at the Champs de Mars.|| Where other circumstances are favourable, such compression is probably adequate to the production of bleeding from the vagina also.

The preceding considerations, will, I think, suffice to show that the entire series of medical facts leads to the following conclusions:—

1st. That the death of Mrs. Kirwan was not the result of apoplexy, or of epilepsy, nor yet of epileptic or of suicidal drowning.

2nd. That the combined conditions of the body (both external and internal) were incompatible with drowning unattended by other violence.

3rd. That the appearances observed may have been produced by strangulation alone, or combined with compression of the chest, or with partial smothering.

4th. That they are also consistent with a mixed process of strangulation and submersion, in which the latter condition was not continuous from its commencement.

\* Paris's Medical Jurisprudence, vol. ii., p. 45. Taylor's Medical Jurisprudence. It was noticed in an executed criminal (Smith's Forensic Medicine, p. 244), and in the case of Jael Denny, reported by Dr. Taylor.

† Mem. de l'Acad. de Méd. 1774.

‡ Morgagni (Epist. xviii.) states that Valsalva found in persons "quos cum sum essent violentia externa strangulavit," the vessels of the tympanum so turgid, that the membrane and the ossicula seemed tinged with blood.

§ Yellowly, Med. Chir. Trans., vol. iv., and Orfila, Traité de Med. Leg., art. "Foudroy."

|| Ollivier d'Angers, Ann. d'Hygiène, v.

The chief circumstances which tends to render the last-named view more probable, are the nature and quantity of the froth observed.

In strangulation, froth is not uncommonly absent, and when present, usually mucous or bloody, smaller in amount, and of coarser structure.\*

The absence of any mark upon the neck is perfectly consistent with strangulation by a soft and broad material. Duchesne (Ann. d'Hygiène, Oct. 1845) inspected the body of a man who hanged himself with his drawers; there was no discoloration, and even the mere trifling depression of the skin was scarcely visible. I examined, in 1848, a similar case of suicidal strangulation with a pocket handkerchief. The depression just described would be at once obliterated by mere motion of the neck.

The scratches and abrasions noticed on Mrs. Kirwan's face, &c., and the lacerated wound of the ear,† most probably resulted from her struggles to procure freedom for the face and neck.

As to the precise details of the mode in which the destruction of deceased was effected, it would be, I conceive, impossible to offer a satisfactory opinion. On the whole, the conditions of the body, with such of the general facts as are intimately connected with them—as the special depths of water and the nature of the locality—are most consistent with the view, that the deceased had been strangled at the land side of the "body-rock" in very shallow water. Whatever may have been the precise spot where the purpose was effected, it seems clear, from the position and clothing of the body, and from other circumstances, that the deceased must have been placed after death on the rock where she was discovered. In determining the person by whom the homicide was committed, the jury were of course guided, as in other cases, by the moral facts. Had the medical details been elicited in a more full and systematic manner, even that question might have been limited within a much narrower compass. The general evidence showed that in addition to maltreatment, the accused had threatened the destruction of deceased; that he had maintained an adulterous intercourse with another woman, who became an inmate of his house shortly after his wife's death; that although his wife had been parted from him for some time on a lonely island, and had not joined him after nightfall, he did not even mention her, when about to depart for Howth. When to this is added, his having caused, as far as might be, the removal of the signs of violence; his suppression of evidence on the latter head; and that, when himself examined as a witness at the inquest, he made no allusion to the fits of epilepsy, which were afterwards urged as the cause of death, &c. &c. With these data to aid their decision, the jury probably felt that the view which assigned to the prisoner the murder of his wife, was more consistent with the evidence, than that which referred it to the agency of fishermen or pirates. In its medico-legal relations, the present case is one of much interest and importance; and should the foregoing outline, the imperfection of which I fully recognize, tend to a more correct estimate of its real nature, my object will have been attained. I trust also that the members of the profession may be induced to register more amply the results of inspections bearing on the questions above discussed.

\* Ecume à grosses bulles (Devergie). That of drowning is fine, and somewhat resembles soap-lather.

† We have already seen that the posture of the body was inconsistent with their production by epilepsy. Their character was equally so. The concentrated motions of the epileptic could not have produced the almost entire removal of the lobe of the ear, nor injuries over such an extent of surface.

## PROCEEDINGS OF SOCIETIES

## MEDICAL SOCIETY OF LONDON.

## CASE OF A BEARDED WOMAN.

DR. CHOWNE rose and said, that in the course of the last year there had been published in the *Lancet* the case of a bearded woman, Josephine B—, who was brought to the Charing-cross Hospital, by a person who stated that she was under an engagement to marry him, and that they wished to be married, but that the masculine growth of hair on her face prevented their being able to get the marriage service performed. Her case was referred to him (Dr. Chowne) as a medico-forensic subject; and under these circumstances, and there being every certainty that she was marriageable, he certified accordingly. He was sorry to add, however, that a public use had been made of the certificate, different from that for which it was given; a circumstance which he exceedingly objected to, and regretted; a use, indeed, not warranted by the circumstances under which it was obtained. On the 29th of last December, Eliza B—, aged 18½, presented herself at the Charing-cross Hospital; and it will perhaps be recollected that Josephine, the subject of his (Dr. Chowne's) lecture, stated that she (Josephine) was the only person of the family to which she belonged who had any similar peculiarity. This, however, appears not to be the case: and as Eliza, who represents herself to be the younger sister of Josephine, was waiting in the Society's library, the Society would have an opportunity of perceiving that, with regard to hirsute growth, she is almost the counterpart of her elder sister, Josephine; and those who had seen both would scarcely fail to recognize a strong personal resemblance. He (Dr. Chowne) considered that the cases, even individually, were interesting; but that the birth of two such instances by the same parents would imply, either on the paternal or the maternal side, the occult existence of some inherent proclivity to the transmission of hirsute growth. Yet of any hereditary origin of such growths in these sisters, there are not any antecedent proofs, so far as can be ascertained. Neither the one sister nor the other has any knowledge, nor is aware of any tradition, relating to their family, further back than their grand-parents. The elder sister (Josephine) stated that her mother's father was remarkable for a large beard, but the younger sister is not aware of its being so. They agree, however, in stating, excepting only as regards the mother's father, that there was not any peculiarity of hirsute growth amongst their grand-parents; that their father was a dark man, but had not a full beard nor full whiskers; that their mother is neither dark nor fair, but intermediate or brown. They also agree in stating that the children of their parents are four, three sisters and one brother; and that a still younger sister and a brother are without peculiarity. Eliza B— states that she is a native of Versoix, in the canton of Geneva, and that, as she is informed, she had at her birth hair on those parts of her forehead and face where it now grows, but that it was soft and of comparatively faint colour; that she had also on her back and limbs an abundance of soft hair. At about five years of age it began to thicken and become a little stronger, but did not grow full and strong and dark, as it now is, until the fifteenth year of her age. The catamenial functions did not appear until she was about 17½ years old; since which time they have been normal. The breasts, although not large, are perfectly womanly. Her head is rather large for a female of her age and stature, but there is nothing peculiar about her throat, as regards its circumference, nor as regards the prominence of the larynx. Her figure and the form of her limbs are feminine; her hands small; and the excessive growth of hair constitutes the only approach to masculine peculiarity about her. The hair on the forehead, face, and cheeks would, if allowed, to grow, cover almost the whole of her face, except the nose and the central parts of the upper lip. She states, that every eight or nine days she shaves the forehead, including a great part of the eyebrows; and also that part of the face from the eyes downward, by the side of the nose, towards

the angles of the mouth; but just above the angles of the mouth she permits the hair to grow. She has an abundant head of hair; that of the front and side of the head is two and a half feet long; that of the back part of the head the same. On the upper part of the bosom there is a small quantity of soft downy hair. Over the back part of the neck and shoulders there is a considerable quantity of hair, and in the hollow formed by the muscles of the neck, and extending down over the spinal column, the hair is sufficiently abundant to cover the skin entirely, and indeed to admit of its being taken up in something like considerable quantity between the fingers. Her limbs, excepting her hands and feet, have a profusion of hair upon them. Her disposition and habits, and occupation, are all those of the female. She has the reputation of possessing great kindness and gentleness of temper. Reverting to the question of hereditary origin, the subject is necessarily one of great obscurity; but still, although it is impossible to have any idea of when—that is to say, in what antecedent generation of the family of these young women—hirsute peculiarity existed, yet that such peculiarity has existed is a fair presumption; for we know how entirely dormant certain hereditary influences may remain through several generations, and still not be extinct. That there has been an hereditary origin is the more probable, when we bear in mind the number of "bloods"—to use a legal expression—or in other words, the blood of how very numerous a lineal parentage runs in the veins of every man. In the first step of ascent, in the lineal line, he has his father and his mother; in the next step he has four, their fathers and mothers; one step further, and he has eight great-grand-parents; proceeding thus, even by the time he has numbered the seventh degree he has 128 ancestors; 1024 in the tenth; and in the twentieth degree or generation, above a million. Thus the difficulty of dealing, not only with hereditary diseases, but with actual personal likeness, and peculiarities such as that now before the Society, is extremely great. The subject of Dr. Chowne's remarks was then introduced and bore out his description in every particular.—*Lancet*.

## CONTRIBUTIONS TO CLINICAL SURGERY.

By ROBERT L. MACDONNELL, M.D.,

Surgeon to St. Patrick's Hospital, Montreal, &amp;c. &amp;c.

## SUCCESSFUL TREATMENT OF A LARGE ENCYSTED TUMOUR ■ PUNCTURE OF THE SAC AND CAUTERIZATION OF ITS INTERIOR.

It will readily be admitted that if we can cure a disease situated on an exposed part of the body, by any means which will not disfigure the patient, or leave an unsightly scar, it must be considered an improvement in surgery; and with the object of doing away with the use of the knife, and substituting a simpler and equally successful practice, I recommended some years ago, in the pages of the *British American Medical Journal*, that many encysted tumours should be punctured, their contents carefully evacuated, and then the lining membrane of the cyst cauterized by means of nitrate of silver conveyed to it on the end of a probe; and that as soon as suppuration or mere effusion of lymph had taken place, that the opposed surfaces of the cyst should be brought together by pressure, and thus obliteration be produced, and a recurrence of the disease prevented. Since that article was published, I have treated in this manner several such tumours, and have never known the disease to return; and as one of these cases was under the care of some practitioners in this city, who proposed removing it by excision, and declared that any other attempt at cure would be improper, I bring its particulars before the profession that they may judge for themselves. A strong healthy young woman noticed a small tumour growing upon the back of her neck, but which caused her no pain. At first it could only be detected by feeling, but it soon became perceptible to the sight, and in the course of two years had attained the size of a turkey's egg; it was elastic, moveable, not discoloured, and handling it gave rise to no pain. From the

fact of its being so prominent, and in such an exposed situation, she was obliged to keep a handkerchief applied so as to cover all the back of the neck. Feeling much alarm at the size the tumour was daily acquiring, she applied to three practitioners, all of whom advised its removal. One in particular was very urgent in his solicitations to be allowed to perform the operation, and took some pains to explain to both herself and her friends the folly of attempting to remove it by an *elliptical* incision, as recommended by one of the others, assuring her that nothing but the crucial incision and masterly dissection would effect the object.

Under these circumstances she consulted me, and having ascertained the nature of the disease, I proposed curing it without leaving a crucial cicatrix, or indeed any mark that could be detected. To this proposal she gladly assented; and accordingly, on the 14th of May, 1849, assisted by Dr. Brookes of Sherbrooke, and Dr. McCallum of this city, who were then my clinical clerks, I proceeded as follows:—A hydrocele trocar was pushed into the tumour, and its contents emptied into a middle sized cupping-glass, which they filled. On examination they were found to be composed of a turbid fluid, devoid of odour, with a quantity of thick, cheesy, steatomatous matter floating through it. The sac being emptied, two or three probes, whose ends were coated with nitrate of silver, were, in succession, introduced and freely applied to all parts of the cyst. A plug of lint was introduced into the opening, and water-dressing applied. The next day, on the lint being removed, a quantity of sero-purulent matter, equal to one-half of what the cyst contained the day before, was evacuated. The caustic was again applied, and the wound similarly dressed. On two more occasions the same plan was adopted, and at each dressing the size of the cyst was perceptibly diminished. Pressure, by means of a compress and adhesive plaster were now applied, and complete obliteration of the cyst was effected at the end of a fortnight. It is now three years since the tumour was thus treated, and she has had no return of the disease; and I need not say is much better pleased to be devoid of the vestiges of such skillful surgery as that so disinterestedly recommended for her relief.—*Canada Med. Jour.*

#### OIL OF THE ARGEMONE MEXICANA AS A REMEDY FOR CHOLERA.

By W. HAMILTON, M.B.

ASIATIC cholera rarely makes its attacks without previous warning, and if individuals would only pay reasonable attention to the premonitory symptoms, much, if not the whole, of the fearful mortality which has already, upon two occasions, desolated our land, might be prevented. The premonitory symptoms usually point to a disturbance of some kind or other in the organs of digestion, which, from whatever cause it may arise, calls for active interference to subdue.

The most obvious mode of answering this indication, is to keep the first passages free, and thus prevent the accumulation of that feculent matter, whose irritation produces the premonitory symptoms, and ultimately leads to that spasmodic action which is among the most painful accompaniments of Asiatic, or, as it has been more aptly designated, spasmodic cholera.

To relieve the abdominal irritation by carrying off the feculent matter which occasions it, purgatives of the milder and least irritating or drastic character should be carefully administered in combination with some anti-spasmodic, to modify their action, and counteract the strong and painful tendency to spasm or cramp, as it is commonly termed.

Now both these objects may be attained by the most moderate doses of the oil obtained from the seeds of the Argemone Mexicana, a plant which flourishes spontaneously in the greatest abundance in waste places, and among rubbish throughout I believe the whole of the West Indian Archipelago, where it may be found blossoming and loaded with seed in every stage to maturity throughout the year.

It is now above eight years since I first endeavoured to direct medical attention to this valuable but neglected plant, through the pages of the *Pharmaceutical Journal*, in the fourth and fifth volumes of which communications on this subject will found.

In the passages referred to, we have the testimony of two experienced practitioners of Jamaica to the valuable aperient, anodyne, and hypnotic effects of these seeds; properties which are also possessed by the oil which they yield, in a more convenient and less bulky form, the dose being restricted to a few drops. The oil will be best obtained from the recent seeds, on the spot where they grow spontaneously; and, as the Pharmaceutical Society numbers among its members residents in the regions in which the argemone flourishes and yields its harvests throughout the year, individuals, it is to be hoped, may be found philanthropic enough to prepare some of the oil with care, so as to guard against the possibility of adulteration, and transmit it to the Council of the Society for a trial of its effects, before we are again subjected to the decimating scourge of that strange and fearful malady which has slain its thousands on the continent of Europe during the past season, and will, not improbably, visit our own shores before another year completes its circle.

It is idle to object that cholera has destroyed its victims in the very island in which both Affleck practised and Barham wrote, unchecked and unmitigated by the remedy proposed, although found at the thresholds of the sufferers. Prejudice is often stronger than reason, and a prepossession in favour of old and what are reputed to be orthodox remedies, too often indisposes us to view with favour those which are unstamped by the signet of time, however strong and however conclusive the testimony of their value.

But the present is an age of inquiry and of research; we are progressively rising above the mists of past ignorance, and learning to withhold our condemnation till assured of its being merited.

Cholera is at hand; and however potent sanitary measures may be in mitigating its ravages, the science of medicine cannot be dispensed with, and when the destroyer comes (as we have too just ground for fearing he will come), the addition of this little article to the artillery of the pharmacist may avert death from thousands, and add a fresher laurel to the triumphs of art.—*Phar. Jour.*

#### ON QUININE AND QUINDINE.

By M. O. HENRI.

It is well known that the manufacture of sulphate of quinine was for several years a branch of trade entirely French. By our example the English and Germans were soon able to extract the quinine from the bark, and, lastly, a manufactory was established on the very ground where this precious tree grows, which threatened to swamp our industry, and, moreover, used up the Calysaia bark, the only kind from which quinine can be advantageously extracted. To meet this emergency, M. O. Henri endeavoured to extract this alkaloid from other kinds of bark which are always abundant in commerce; and, owing to the perfection of his process, he has succeeded in considerably abating the price of quinine. But now the English and German chemists pretend that the quinine extracted by M. Henri from different kinds of bark is nothing but quindine; a substance, according to them, essentially different, and which does not possess the same febrifuge properties. To combat this hypothesis, M. O. Henri read a memoir to the Academy to prove that the substance prepared by him is truly sulphate of quinine, and that the substance described by the English and Germans by the name of quindine, is nothing else but quinine in the state of hydrate.

Quinine is found in greater or less abundance in all barks; but a curious fact, and one rather difficult of explanation, is that in the red bark of New Grenada the quinine is found as a hydrate. There is, then, no reason to abandon the extraction of quinine from all kinds of cinchona bark, the price of which is much less.—*Jr. de Méd. et Chir.*

## DISLOCATION OF THE CRYSTALLINE LENS.

Treated by Mr. HOWARD, M.R.C.S.,  
Surgeon to the Montreal Eye and Ear Institution.

JOHN N——, aged 52, was received into the ophthalmic ward of St. Patrick's Hospital, April 8, 1852. The history he gave of his case was, that ten days previously he received a blow on his left eye which deprived him of sight, having been nearly blind of the right eye for thirty years. The following are the appearances his eyes presented:—A dense cicatrix across the lower half of the right cornea, the remaining portion of the cornea opaque from lymph deposited in its layers. Left eye turned outwards and downwards, with no power to move it from that position, owing to a hard round tumour on the upper and internal portion of the sclerotic and beneath the conjunctiva. The surface of the tumour pressed against the anterior and internal angle of the roof of the orbit. The natural pupil was closed, but there was a large triangular artificial pupil in the inferior portion of the iris, caused by the iris being detached from the ciliary ligament in that particular part. There was also a small pupil about the size of a small pin's head in the upper and external part of the iris, and part also detached from the ciliary ligament. The whole eyeball was inflamed intensely; the sclerotic a deep red, the iris a dark green. I at once diagnosed the case to be a dislocation of the lens through the choroid and sclerotic coats, forming the tumour described above under the conjunctiva. I made an incision through the conjunctiva covering the tumour, and had the satisfaction to find the lens fall into my hand, the eye immediately after resuming its proper position. I then covered the eyelids with a pledget of lint, sent my patient to bed, ordered him low diet, and one grain of calomel with quarter of a grain of opium every six hours. The next day the eye felt very painful, and upon examining it I found a tumour occupying the same spot from which I removed the lens the previous day, and producing the very same effects as before the lens was removed. I saw that the incision I had made the past day had cicatrized, and that the space which the lens had made for itself in the subconjunctival cellular tissue had secreted a fluid which caused this second tumour. I then took hold of the flaccid tumour in a pair of forceps, and cut it off with a pair of curved scissors, after which the eye again resumed its natural position. I again applied a pledget of lint, and continued the same treatment ordered the first day. The third day following I again examined the eye, and found the part from which I had removed the cyst healed. I did not close the eyelids again, but ordered the calomel and opium to be continued. On the 15th, seven days after his admission, there was slight mercurial fever, and with the injured eye he could see my hand move between him and the light from the window. The inflammation of the eye was very much subdued. I then put him on the solution of biniodide of mercury, discontinuing the calomel, ten drops twice a day, and ordered that he should have soup diet. On the 19th all the inflammation of the eye had disappeared, and he was able to distinguish the different patients in the ward. I then discontinued all preparations of mercury, and put him on hydriodate of potash, two grains every eight hours; I also gave him a more free diet, and permitted him to go about the ward. On the 10th of May, one month and two days after his admission, he was discharged, having as good sight in the injured eye as is generally found after the removal of the lens by operation. The day following I met him walking through the crowded streets as brisk as any man. During the time he was in hospital, I every day touched the old diseased cornea with some stimulating lotion, such as the diluted liquor potassæ, the hydrocyanic acid, and the nitrate of silver; so that when he was leaving the upper and lower parts of the cornea were perfectly clear, leaving the greater part of the pupil and iris visible: of course the cicatrix across the cornea remained.—*Canada Med. Jour.*

## POISONOUS PROPERTIES OF FISH.

Queries By Mr. W. HAMILTON, M.B. of Plymouth.

THE second volume of the journal of the Royal Geographical Society, contains an interesting paper of "*Remarks on Anegada*," one of the group of Virgin Islands, a group but too notorious for the dangers of its navigation and the consequent frequency of shipwrecks. In this paper, which was furnished to the Society by Mr. Schomburgk, a member of the Horticultural Society of Berlin, and evidently a man of observation and science, occur the following remarks upon the properties of the fish in the surrounding sea,—which correspond in a great degree with my own recollections of times gone by, and exemplify, without explaining, that mysterious cause which renders the same fish at one time, and in particular localities, injurious to the human frame, and at other times, and in other localities, perfectly innocuous. Mr. Schomburgk thus states the fact, and asks the cause: "The surrounding sea abounds in good fish, to which the ponds add likewise their number; without entering into details, I mention only one fact, which deserves a strict investigation. It is well known that the yellow-billed sprat [*Clupea* or *Thrissa*], barracouta [*Perca*, Browne], the bottle-nosed Cavalla [*Scomber*, Browne], rock-fish [*Perca marina*, Catesby], and sometimes the king-fish [*Xiphias*], are occasionally poisonous, and are known to have caused immediate death. To what the poisonous quality of these fishes is to be attributed is very uncertain; it has been supposed that their feeding upon copper banks, of which there are some at St. Eustatia, renders them poisonous; others deny this, and attribute it to their feeding on narcotic submarine plants. However, though frequent accidents happen in the neighbouring islands, not one instance of fish poison has been known in Anegada: and the yellow-billed sprat, the largest barracouta, and even the amber fish [?] are eaten with impunity. Who can solve this enigma?"

Mr. Schomburgk then proceeds to investigate the various hypothetical causes alleged for this curious phenomenon, but without throwing any additional light upon it. I shall now state one or two facts from my own recollections but without attempting to assign a cause for them, in the hope, that others, possessing time and opportunity, may be led by them to investigate their cause.

The yellow-billed sprat, spoken of in the preceding extract, is in the islands of Nevis and St. Kitts, one of the most rapid and deadly poisons known, during eleven months out of twelve, there being but one month [that in which the black cherry, a species I believe of *Myrtus*, is in flower or in fruit, I forget which] in which it may be eaten with impunity. This month is, if I recollect aright, April, or at all events one of the vernal months. At all other times, it is so deadly, that a negro girl has been known to drop down dead while in the act of eating and with half the fish yet in her mouth. May not the exemption during this solitary month arise from some physical change in the constitution of the fish, and is it common to both sexes? Yet upon this supposition, how are we to account for its freedom from noxious properties throughout the entire year?

All the fish taken on the N. W. coast of St. Kitts, and between it and the adjoining island of St. Eustatia, are said to be poisonous, although fish of the very same kind taken on the other coasts of the island are harmless. The barracouta, the king-fish, the horse-eyed cavallee, and even the dolphin are at times poisonous; but this quality in them appears to arise from incipient decomposition, since a portion of dolphin which had been cavished, poisoned those who partook of it in the morning, although they had eaten it freely the preceding day at dinner when fresh: and I have myself dined off a barracouta, which a few hours after nearly proved fatal to some negroes who ate what was left. A usual test for the wholesomeness of fish in the West Indies, is the insertion of a silver spoon into the water in which it is boiled, when, if the silver be tarnished, the fish is rejected. This seems to mark incipient decomposition, accompanied by a disengagement of sulphuretted hydrogen. But this will not account for the

periodical wholesomeness of the yellow-billed sprat at Nevis, or the fact of all the fish caught off Aneгада being harmless throughout the year. I must with Mr. Schomburgk, "acknowledge myself negligent in not having investigated this point before"—at the same time that I hope that this admission of negligence may serve to awaken the industry of others, and obtain for society the ultimate solution of a problem at once so important, so mysterious, and so curious.—*Pharm. Jour.*

### ON THE NATURE AND CAUSES OF THE PHYSIOLOGICAL PHENOMENA.

By STANHOPE TEMPLEMAN SPEER, M.D.

It is, I believe, very generally admitted, that when an individual habitually residing at a moderate elevation above the level of the sea, attains in a short space of time a considerable altitude above such level, he will in all probability experience certain deviations from his ordinary condition of health, sufficiently marked to constitute, for the time being, a state of actual indisposition, if not of disorder.

Now, in examining the narratives of those who have been most qualified from personal experience to investigate the subject, we find much discrepancy existing; not merely in relation to the nature and intensity of the phenomena in question, but even as regards their very existence.

Having however experienced on several occasions, to a certain extent, the effects of a rarefied atmosphere, upon some of the loftiest Pennine Alps, I venture to offer a cursory view of the subject, in reply to the three following queries, which it naturally suggests—1st, as to the actual occurrence and nature of the physiological phenomena alleged to be experienced at great heights? 2nd, are these felt by all persons alike and at the same height? 3rd, what are the causes, and whence the explanation, of such phenomena?

A reply to the first of these inquiries, that which refers to the actual existence of an abnormal condition of the body at a great elevation, is to be sought for by reference to the somewhat scattered accounts here and there afforded by those, who, whether from curiosity or for scientific purposes, have scaled the loftiest summits of the great mountain chains of Asia, America, and Europe.

It need scarcely be said, that the information to be derived from those in whom somewhat more than curiosity constitutes the stimulus of enterprise, is by far the most valuable; not but that the courageous though unreflecting explorer of the higher Alps may occasionally be heard to complain on his return, of having experienced certain disagreeable sensations to which he had hitherto been a stranger; the rapid subsidence of which, however, on regaining the usual level, would render them (in his estimation) merely worthy of a passing remark.

Various circumstances combine to produce that diversity of opinion which is to be met with, relative to the phenomena in question. In the majority of instances, the ascent of a lofty mountain is undertaken as a pleasure excursion without any definite object; it may have been prompted by a love of *à-clât*, or, what is more to be admired, by a thirst after the beauties of nature, and a wish, in spite of danger and peril, to approach as near as possible to her noblest works; and as a rule, with but few exceptions, the feelings elicited on such occasions are totally opposed to a careful and impartial examination of facts, for sensations, which under every-day circumstances might be dwelt upon in detail, are now almost disregarded and absorbed in sentiments of a higher and less corporeal nature.

Another cause for the above-mentioned discrepancy relative to the subject in question, arises from the peculiar circumstances under which the ascent of a lofty mountain is usually made. The majority of those who undertake such an enterprise, are comparative strangers to mountain scenery and mountain exercise. They spend a day or two at the foot of these mighty masses, and forthwith proceed at once to attempt to scale the object of their ambition.

Here everything is novelty of the highest order. The succession of wonder-striking scenes which they now behold, it may be for the first time, the rapidity with which marvel succeeds marvel, the bewildering sensation experienced, when first encountering those extraordinary objects of which no description can give an adequate idea, the glaciers, the feeling of dread occasioned by the ghastly aspect of their gaping crevices, the thrilling sensation momentarily produced by the dreaded sound of the falling avalanche, and last, not least, the all-absorbing sentiment of triumph, resulting from the safe and successful termination of an attempt, the accomplishment of which may have been, for some time previous, the object of thoughts by day and dreams by night; these circumstances, I repeat, are sufficient to burden and embarrass the mental perceptions of the tourist. His memory becomes crowded with a variety of souvenirs and facts, which ere long, by their very number and intensity, destroy one another. On his return to the ordinary dull routine of life, the thrilling events of the past stand out in still bolder relief to the monotony of the present; his imagination outruns his bewildered memory, and he pictures to himself and others, scenes and circumstances which he may conceive to be correct, but which not unfrequently, upon close inspection, bear the evident imprint of fancy preponderating over fact. Viewed in this light, it can be no matter of surprise, that he should either forget the corporeal annoyances he may have experienced, or that he should make light of them, and throw doubts on the veracity of others more keenly susceptible to physical impressions than himself, and more bent upon the calm appreciation of certain facts, than upon the enjoyment of the most exciting gratification. It is not unreasonable to suppose that, in the case of many Alpine ascents, the individual (unless completely prostrated), resembles the soldier on the field of battle, the pain of whose wound, if not sufficient to disable him, is unperceived until the engagement be at an end; so with the Alpine tourist, his physical sensations, unless strongly marked, being swallowed up in the interest of the moment, are thus not only disregarded during their actual existence, but from their rapid subsidence on returning to an ordinary level, are excluded from a prominent place in his after recollections.

In the records, however, of such travellers as Humboldt, Boussingault, d'Orbigny, Zumstein, Saussure, Pictet, and others, there are to be found many valuable and accurate references to the sensations experienced at great heights, more especially among the Andes and the Himalaya; for while the region of the higher Alps is that to which the present remarks have chief reference, the superior elevation of the two afore-mentioned chains would naturally lead us to suppose, that the attempt to scale their loftiest summits should have afforded marked examples of those functional modifications to which I have alluded.

The celebrated Humboldt ascended the peak of Teneriffe, without experiencing dyspnoea or any unpleasant sensation whatever. This was also the case with his travelling companion. When among the Andes he determined to attempt the ascent of Chimborazo, one of the loftiest of the whole chain: he had previously resided, for a certain length of time, on the table-land of Quito; from thence he proceeded with Bompland and Montufar to the plain of Tapia, and having slept at Calpi at an elevation of 9471 feet above the sea level, they began to surmount the inferior terraces of which the mountain is composed; at a height of 13,155 French feet, they saw snow that had lately fallen, and at length attained a height of 16,724 feet without material inconvenience. The Indians, however, who accompanied Humboldt, had, with one exception, turned back at a height of 15,201 feet, alleging that they suffered far more than their employer. The following is Humboldt's description of the sensations which he at this moment perceived: he says, "after attaining an altitude of 16,724 feet above the level of the sea, we continued to ascend for another hour, during which we all became by degrees much distressed: a constant desire to vomit, together with vertigo, were the most prominent symptoms, and proved far more trying than the difficulty of breathing which we likewise suffered

from. An inhabitant of San Juan who had accompanied us, although robust, was still more affected. In all the blood started from the lips and gums, while the conjunctiva, covering the eyeball, was in each of us distended with blood. On the Antisana, Montufar likewise experienced a certain amount of hæmorrhage from the gums. All these phenomena however differ essentially, according to the age and previous habits of the individual, to the thinness of his skin, to the amount of muscular exercise to which he has been accustomed, &c. They, however, serve to afford each one, a sort of measure of the rarefaction of the air, and of the altitude attained. In the Andes, they manifest themselves when the barometer stands at from 0 min. 379, to 0 min. 428. We continued to ascend for three hours and a half beyond the limits of perpetual congelation, and, in spite of the rarity of the atmosphere, we had not found it necessary to take any repose." The greatest height which Humboldt at length reached was 17,634 feet.

(To be continued.)

#### REVIEWS AND NOTICES OF BOOKS.

**CLINICAL REPORTS ON OVARIAN AND UTERINE DISEASES; with Commentaries.** By ROBERT LEE, M.D., F.R.S., &c. London. 1853. Fcap. 8vo. pp. 340.

It is most gratifying to see a physician of eminence and ability publishing the results of his clinical experience, and laying before his brethren the contents of his private case-book. Such instances amongst men of standing and of acknowledged merit are, unfortunately, rare. The medical aspirant to fame, the young physician or surgeon, is apt enough to record in print his various cases of successful treatment or happy diagnosis; but this is often so manifestly done with a view to making a name, that, somehow or other, we cannot receive these histories with the same full and implicit confidence, nor attach the same degree of importance to them, as if their author were a man of established reputation and matured experience. It is, therefore, with feelings of much satisfaction that we hail the appearance of this book of Dr. Lee's; and so highly do we estimate its utility that we are strongly inclined to think the profession will look upon it as equal, if not superior, in value to any of his former publications, admirable though all these were. Most sincerely do we hope that the worthy example thus set by Dr. Robert Lee may be imitated by other men of equal eminence in other branches of medicine.

Of modern British accoucheurs, there is hardly one who has done so much for the advance of obstetric science as Dr. Lee. In every subject relating to obstetrics—viz., in anatomy, physiology, pathology, and practice, his name holds a prominent place; whilst by his persevering and successful efforts to expose some of the abuses of the vaginal speculum, he has gained the respect of all upright and honourable men, and has, moreover, rescued a most valuable auxiliary to physical diagnosis from becoming a mere instrument of extortion and quackery in the hands of unprincipled persons.

The nature and scope of this work are told in a few words. It consists of five reports, chiefly upon the diseases of the ovaria; the malformations, organic diseases, and prolapsus of the uterus; and in each report we first have the author's remarks upon the subject under examination (in a great measure, if not entirely, from some of his published papers), and then follow the clinical histories. These are given in the most concise manner, and free from all extraneous or unnecessary matter. The entire number of cases related amount to about five hundred; and, taken as a whole, they constitute, we hesitate not to say, the most valuable and extensive collection of clinical facts that has yet been published in this department of medicine. We shall transcribe a few histories, selected at random, that the reader may be enabled to form some general idea of the author's style and mode of communicating facts:—

"Case 106. August 27, 1847: Mrs. D—, aged 49, nine

children, several miscarriages, catamenia disappeared two years ago. In April it was ascertained that a tumour of considerable size existed in the lower part of the abdomen. A continued inclination to pass the urine experienced; leucorrhœa. I was requested by Dr. Arnott to see this lady with Mr. Tobias Brown. The os uteri was tumid and open; several nabothian glands enlarged; a great hardness on left side, occupying the cavity of the pelvis; abdomen swelled; dull sound on percussion; distinct fluctuation. The enlargement has been increasing rapidly of late. It went on augmenting during the two succeeding years, and, after repeated tapping, the case terminated fatally.

Case 5. September 7, 1853: Sarah C—, aged 22. Had long been in delicate health, had suffered much from nervous headache, dysmenorrhœa, and profuse leucorrhœa in the intervals. Looks pale and dejected, and complains of pain in the back and in the left side of the abdomen, increased by pressure, between the umbilicus and ilium, extending down the thigh. There is no hardness or swelling in this situation; the pain comes on in paroxysms; no blood passed with the urine, and no evidence of disease in the kidney."

We have transcribed this case exactly as we found it, without addition or subtraction. It is one of a group, sixty-five in number, apparently designed to illustrate "disorders of the uterine functions." As a whole, they are far inferior in value and practical application to the other collections of cases contained in the volume; in many instances the history is so imperfect, and the data so scanty, that no opinion can be arrived at as to the real nature of the case. In the one above quoted, there is good reason for thinking that some uterine disease existed, which might have been revealed by the use of the speculum.

"Case 47. Last autumn I was requested to see a lady, beyond the middle period of life, who had long been labouring under the most common symptoms of cancerous ulceration of the uterus, and was believed by her medical attendant to be dying of cancer. I found the os and cervix uteri nearly in a healthy condition, encircling the root of a polypus, in a sloughing, disorganized state. I applied a ligature without difficulty around the root of the polypus, and it came away in the course of a few days. The patient, however, continued to get weaker, and died."

The most natural question that presents itself after reading this history is, what the cause of death was? The narrator would have been the most competent person to have answered this, but as he has not thought proper to do so, neither shall we. A few comments, however, would have greatly enhanced the value of the record.

"Case 31. On the 2nd of March, 1829, Dr. Elliotson showed me the uterus and ovaria of a female aged 28, who had died in St. Thomas's Hospital. She was unmarried, and there was no derangement of the functions of the uterus, except that she menstruated every fourteen days instead of every month. She died from peritonitis, apparently produced by a morbid condition of the ovaria, Fallopian tubes, and uterus. Both tubes were greatly enlarged, their muscular coats of a gristly hardness, and their canals, which were unusually capacious, contained a dark-coloured purulent fluid. The fimbriated extremities, which were large, hard, and ragged, and their surface ulcerated, adhered to the ovaria by false membranes; portions of lymph, recently effused, were also present. Both ovaries were enlarged, and contained small cysts filled with a dark-coloured fluid. The coats of the uterus at its fundus were softened, and yellowish points, here and there, were visible in the muscular tissue. The mucous membrane of the uterus around the entrance of the tubes had also a peculiar yellow colour and soft consistence. I regarded this as a case of malignant disease of the Fallopian tubes extending to the uterus."

We shall give one case more; it is from the last series of cases in the book, entitled "prolapsus of the vagina, uterus, rectum, and bladder."

"Case 42. August 10, 1842: Mrs. P—, aged 37; married one year; never pregnant; had prolapsus of the uterus sixteen years before; since her marriage the protrusion has greatly increased. Consulted Dr. —, who introduced a boxwood globular pessary, which she wore for several years without being removed to be cleaned, and it was necessary to have it broken in pieces before it could be withdrawn: the

discharge had become horribly offensive before this. Since then the parts protrude when she walks across the room. There is great leucorrhœa; catamenia regular."

We do not give any extracts from the other portions of the work, as they are already well known to the profession. We are sorry, however, that Dr. Lee did not make some additions to them. It can scarcely be possible that his more enlarged experience, subsequently to their original publication, could not have enabled him to do so, and thereby to have greatly enhanced their practical value. Should the work reach a second edition (as no doubt it will), we trust its author may act upon this hint, and leave no room for a repetition of the regret we have expressed.

Dr. Lee strongly condemns the use of the speculum in all cancerous diseases of the uterus, as serving no good purpose, whether of diagnosis or of treatment. In these remarks we cordially agree; and are strongly of opinion that in many cases of this class, its introduction is decidedly injurious to the patient, without in the least degree aiding the diagnosis. On the other hand, it is underrating the utility of the instrument to suppose that it is only advantageous "in some cases of inflammation and superficial ulceration of the uterine orifice;" more especially so if the experience of others corroborates that of Dr. Lee, when he states that "neither in the living nor in the dead body has he ever seen ulceration of the os and cervix uteri, except of a specific character, and especially scrofulous and cancerous." With a little latitude of interpretation, however, this class of "specific ulcerations" may be very comprehensive, and include a vast number of cases.

We must confess to having felt disappointed in finding only a brief notice of Dr. Lee's experience, and no deliberate expression of his opinion, upon some of the obstetric novelties of the day: such as the uterine sound, the hysteriotome, the stem-pessary, &c. From the tenor of his few remarks, however, it is plain that Dr. Lee is not more favourable to these alleged improvements than we are ourselves; but still we think the candid, straightforward avowal of his opinion would have been calculated to do more good than the indirect ironical mode of condemnation which he has adopted. The cause of truth is always best advanced by full, free discussion; and when a man's sole object is its attainment, he has no need to employ such weapons as irony, satire, or ridicule.

We heartily recommend Dr. Lee's clinical record to the attention of all physicians who make the diseases of women their special study.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, JANUARY 26, 1853.

### "EXAMINATIONS REAL, NOT VERBAL."

UNDER this head we find in the ASSOCIATION MEDICAL JOURNAL, formerly "THE PROVINCIAL," the annexed "leader" on a very important part of the machinery of Surgical Education. We copy it, although we do not entirely concur in all the opinions offered, because we see clearly that the period has arrived for a free inquiry into the merits and defects of our present system of examination; and also because we cannot permit our juvenile contemporary to "run away with the question" after the following fashion, without a little friendly dissent:—

Great improvements and great discoveries, when known, seem to be so simple and obvious, that the wonder to all is that they were never adopted or found out before. And there are few more simple and obvious improvements, and none perhaps of more vital importance, than the addition of *real* to *verbal* examinations, by the Examining Board of the University of London. A century hence, the mode in which stu-

dents are now mostly educated for medical and surgical practice, will, we trust, hardly be credited. The plan hitherto has consisted in crowded lecture-rooms, while the attendance in dissecting-rooms, botanic gardens, chemical laboratories, and the wards of hospitals, has been miserably scanty. Young men have assiduously worked at books in their own rooms and under grinders, and have let slip the most precious opportunities of learning their profession. They have piled themselves with the thoughts, opinions, and acts of other men, without gaining the power of thinking or of observing at all. Who does not look back with a sigh, or with a more bitter feeling, at a system which compelled him to go from lecture-room to lecture-room, to hear for the most part *words*, in order that he might pass an examination of *words*;—the one fit to him, and the other to convince the world that he was fitted, to practise, not a language, but a practical art and a science dealing with *things*? The whole system—teaching, grinding, and examining—was exactly calculated to make him believe that he had only to commit to memory a certain number of words, in order to cure disease: a most cruel treatment, nicely calculated to raise his hopes in order to disappoint them, to foster all his conceits at his acquirements, in order to show the falseness of their foundation. He was sent away with prizes and medals and parchments, which proved, not that he had in any way mastered his art, but that he knew how to talk about it. Now the fault which lies at the very bottom of this system, and on which it rests, is the examination at the end. Improve that, and the other must correct itself. Examine the candidates in *things*, and not in *words*, and they must know the things and not merely the words representing them. Test anatomy by dissection, and the dissecting-rooms will be well attended. Test chemistry in the laboratory, and that will be the place of chemical study. Test surgery and medicine by the actual examination of patients, and the bedsides will be surrounded. This plan has been commenced by the University of London, and must sooner or later be followed by the other examining boards; and we feel convinced that the actual improvement in medical education will be rendered greater by this single alteration than by any new curriculum, however comprehensive. We will conclude with two instances of the working of the present system. Two students competed for a botanical prize: one has since proved himself an original botanist of the highest accomplishments. At that time his knowledge of plants was marvellous. He could tell any species, name it, and give the natural order, even in Kew Gardens, and his acquaintance with structural botany was great. The other knew something of the botany of his district, and little more, but very carefully got up by notes the lectures they were attending; and although not fit to hold a candle to the other, he ran him so hard in a written examination, as to be within a few figures of gaining the highest prize. He had sufficient self-knowledge to be glad that he did not. In the second instance, the very worst house-surgeon inflicted on a public hospital, was the highest prizeman in his college, and was elected on the strength of his prizes. His abilities were excellent; but he had devoted with diligence all his powers to the acquisition of *words* from books, and broke down in an appointment which demanded a knowledge of *things*. The system has been to blame, not the student; and we thank the University of London for having begun prominently to adopt a more scientific mode of examination, and for thus giving us the promise of a more capable set of junior practitioners.

Now, we cannot share in the enthusiasm of our ardent brother when he so affectionately assigns to the London University the honour of "the discovery," that *real* examinations should be added to *verbal* ones, because we know that other institutions have been endeavouring to effect this object before the London University was born; and because we know, that the method has not yet been practically tested under the operation of its regulations. And why? Just because such things are more easily said than done. Doubtless, a man who can display by dissection the anatomy of a part gives better proof of skill and knowledge than the man who repeats the grinder's lesson; but *anatomy* is not to be learned by dissection for all that. What is appropriately called Surgical Anatomy, can be mastered in no other way; but Anatomy, as the foundation of Physiology and Pathology, must be learned by other

means, and by other means must a knowledge of it be proved. This convenient doctrine touching the all-sufficiency of dissection, or what is commonly called dissection, to perfect a youth's anatomical education is, we know, a prevalent one, for it enables a man to "set up" for an anatomist, and to get "recognized" on the strength of a putrid extremity, or a tray of abdominal viscera; but it is unsound doctrine. Neither can a candidate prove his knowledge of Chemistry, by going through experiments in a laboratory, nor his knowledge of Botany by demonstrating the parts of plants on recent specimens. In an hospital, too, he will be unable to establish his acquaintance with disease in general, however he may be able to form a correct diagnosis and suggest a treatment. Words must, after all, have their weight; for it is by words that ideas are communicated. Men in fact must read books, listen to lectures, and answer questions before they can be accepted as Physicians or Surgeons. Still let us not undervalue the advice above given, tending as it does to improvement in an essential department of medical education, but rather let us encourage such discussion, for assuredly the state of the case demands a thorough scrutiny. Our own conviction is, that the fitness of a man to undertake the treatment of disease could be easily ascertained by judicious examination, and that the present confessed insufficiency of the test might be easily remedied; but then who will dare to do it, wound up as personal interests and private affairs are with the present vicious arrangements. As long as men are paid for doing a thing wrong, so long will they resent any attempt to have it done right? At the moment we write, the Colleges of Surgeons of Dublin and London are engaged in a consideration of this subject with a view to its elucidation; but so strong is the ruling passion, that a perfect storm of indignation has arisen lest certificate money, hospital dividends, or examination fees, should be reduced by any change. This appears to us not only very unreasonable but very impolitic. There is a homely saying, that "there are more ways of killing a dog than hanging him," and if the student is to be ground and squeezed, we see no reason why he may not be as well dealt with by one contrivance as another. Indeed, it is probable that much more may be extracted from him by separate processes, conducted by different operators, than by any combination of methods by coöperating manipulators.

#### MEDICAL JOURNALISM IN ENGLAND.

BE the cause what it may, it is obvious that the old high-roads to the temple of Æsculapius have become less attractive to medical pilgrims. Within the last year two or three have been shut up, and others have had by-roads opened from them into other paths; while that by which provincial travellers wended their way has undergone a thorough repair, and some alteration in direction. In other words, the journal of the "Country Doctors" of England, formerly "THE PROVINCIAL," has become the "ASSOCIATION MEDICAL JOURNAL," and starts with professions of improvement. This being so, we think it not out of our province to suggest some doubts as to the following intimation contained in its programme:—

Of the great superiority of such a periodical, both as regards economy and independence, over every similar undertaking of a merely commercial character, there cannot be any reasonable doubt; and the opportunity now presented of raising the standard and improving the tone of our medical periodical literature is one we should eagerly embrace. It is intended that the new journal, while it retains its original character as the organ of the Association, should secure, at

the lowest possible expense, all those advantages which a weekly periodical is capable of affording; and that it should, by presenting a faithful digest of medical literature and science as well as an attractive summary of professional news, render the purchase of any other periodical a matter of choice rather than of necessity.

Now, we cannot see the "superiority as regards economy and independence" over journals "of a merely commercial character" here assumed; for to say the truth, our new contemporary savours as much of the trade and shop as any we know: so much so, that it appears to us that the Provincial Association has become to all intents and purposes a Joint-stock Journal-publishing Company; deriving income from the sale of their publication and the insertion of advertisements. We neither object nor complain, all we venture upon is a hint as to the possibility of a feeling being entertained that such a course may be *infra dig.* At all events, we cannot see that it forms grounds of congratulation; moreover, we cannot discover that the plan is particularly calculated to secure the "independence" claimed, for we cannot believe that if a little wholesome advice to General Practitioners becomes necessary, it will be particularly relished if given by their own organ. Then as to the Journal "rendering the purchase of any other periodical a matter of choice rather than of necessity," we cannot say that we rejoice; for we know not any body of men more likely to be improved by a more enlarged acquaintance with medical literature than our English provincial brethren. They have hitherto been kept in the dark sadly as to the true state of professional knowledge, and the sooner they are enlightened the better. Doubtless, this frank avowal of our opinions on this score will prove unpalatable, but when our nearer relatives here in Ireland require a little stimulation, it is not praise we administer, but something more efficacious.

#### RIGHT OF PRACTICE IN ENGLAND.

THE state of the law which influences, not regulates, medical practice in England, is disgraceful. The utmost facilities are afforded for the quack's depredations, and every interruption is given to regular practitioners, not of "the body." We are glad to find that the parties concerned are becoming either ashamed or afraid to persevere in such doings:—

The necessity for some comprehensive system of medical reform must be acknowledged by all those who pretend to any acquaintance with the condition of the profession. Assailed from without to an unexampled extent by illegal practice and quackery, the danger from within is not less imminent, from the great variety of qualifications which the practitioners of medicine consider entitle them to practise. Legally, it must be remembered that no person can practise as an apothecary without the licence of the society. No matter whether he be

a Doctor of Medicine in any university, or a member of any college, or that he may have taken the highest honours, the moment he "attends, prescribes, and dispenses for a medical case for gain," unless he be a licentiate of the Apothecaries' Company, he is liable to an action for penalties. As might be expected from such an anomalous condition of things, cases are constantly occurring which indicate the necessity of some important change. However valuable may be the services which the Society of Apothecaries have rendered to the profession and the public, and however necessary, at one time, it might have been to carry out their penal clause to the letter, it is evident that to do so now would be attended, in many cases, with the grossest injustice. The gist of our remarks are in opposition to that by-law of the association which contemplated the prosecution of members of the College of Surgeons who, practising "generally," did not possess the certificate of the "Hall." One would think that in using the term *qualified* practitioners, our meaning was sufficiently clear. Some, however, have conjectured that the remarks applied to persons who practised without any diploma

or certificate whatever. Far from it. We perfectly agree with all who have addressed us on the necessity of prosecuting such persons; and we invariably have recommended that evidence should be procured against them, and the penalty sued for in the County Court. So much, then, for that objection to our views. Now for the more important and more plausible one. The apothecary is the only legal "general practitioner," and consequently only he should be allowed to practise "generally." Now we admit the fact—we admit the deduction. But mark the result if this were to be the established practice. We open a crusade against a body of highly intelligent and qualified men, who hold the certificates and diplomas of other bodies, at least of equal standing with the Society of Apothecaries; and further, we acknowledge that a person possessing merely the Hall certificate is competent to treat all cases, though it is well known that a surgical question is never asked at the Hall. Admit that the examination of the College merely tests the ability of the candidate as to his competency to meet "the common exigencies of surgery;" still, we contend that the mere apothecary has no right to place himself on a higher position as a practitioner even in a legal sense, than the mere surgeon. What, then, do these anomalies in the profession indicate? Do they not clearly show the necessity of some forbearance upon the part of qualified medical practitioners towards each other? Undoubtedly they do. They show that there is an absolute and increasing necessity for a common entrance into the profession—one that must be made compulsory, that will embrace an examination in all branches of medical and surgical knowledge; that shall not be confined merely to pharmacy, midwifery, and medicine; nor, on the other hand, to the mere alphabet of surgery;—but a test that will try the candidate in all branches, that will prove him to be fit for all exigencies, and will entitle him by law to practise in every or any department of his profession. A candidate so qualified should be protected from the quack and impostor, and he should be entitled to reach the highest position which it is possible for a medical practitioner to attain.—*Lancet*.

#### UNBLEACHED DISULPHATE OF QUININE.

UNDER the name of "Hospital Sulphate of Quinine," an unbleached sulphate or disulphate has been introduced into the drug market. It is prepared by Mr. Edward Herring, and is sold by Hulle, of Trinity-street, Southwark, London. In the advertisements, it is stated to be at least as pure, and 20 per cent. cheaper than the white salt. The following is the account which the proprietor gives of the substance. He says—"The crystalline form is the same, and is in every respect identical with the usual white article, with the exception of the one being bleached and the other unbleached. In refining the white, or bleached article of commerce, by the usual agency of animal charcoal, the sulphuric acid acts upon the lime of the charcoal, and great care is necessary to preclude the inadvertent contamination of sulphate of lime. The "hospital," or unbleached sulphate of quinine, is prepared without the aid of animal charcoal, rendering the presence of salts of charcoal impossible. The peculiar mode of preparing both the sulphates of quinine of this establishment is being patented, and therefore the process of manufacture will be made public." We have examined a specimen of the unbleached, or "hospital" sulphate, which was forwarded to us by Mr. Hulle, and we can report in its favour. Save the merest trace of inorganic colouring matter, it contains no foreign substance. It differs in aspect from the pure colourless disulphate, its crystals being larger and denser. Not having made a quantitative examination, we cannot say whether the preparation be a sulphate or a disulphate; but we are satisfied that it consists only of quinine, sulphuric acid, water, and a trace of colouring matter, and that it is therefore as good for medicinal uses as the white and pure disulphate. We are willing to admit that, as a general rule, it is wrong to sanction the use of medicines which are not absolutely pure; as by so doing, we are apt to afford temptation and facility for their adulteration. We think, nevertheless, that we ought to report favourably as to the value of the unbleached salt, because we have found that for medicinal purposes, it is entitled to be called pure; and because by its smaller price, we may enable many to benefit by its use, who could not afford to employ the white salt.—*Association Medical Journal*.

We can now add our testimony in favour of this preparation from reports as to its value furnished from the City

of Dublin Hospital and elsewhere. Ireland, of all places in the world, requires a cheap and efficacious form of this essential tonic, and we hope that the poor may have the benefit of this one. We know not how far the drugs supplied to the Dispensaries have been subjected to scrutiny, but the sooner so important a proceeding comes to be adopted the better; and in such case the matter here alluded to will have the consideration it deserves.

#### LOCK HOSPITALS.

THE letters of Dr. Rose, published some time since, prove the necessity for the interference of the government at our chief naval stations, relative to the formation of some establishments by which one of the great torments of both services might be abated. We allude to the institution of "Lock Hospitals," particularly for the treatment of diseased women, who now render these stations the very foci of the syphilitic virus. That venereal complaints are dreadfully rife among soldiers and sailors, is unfortunately too true; that the treatment and cure of them costs a great deal of money, is not less so; and were it not, for the extreme, but often very disagreeable vigilance of the medical officers in the examinations, in endeavouring to detect the earliest symptoms of the disease, matters would be infinitely worse. That the *filles publiques* of our great sea-port towns are not only affected in a higher ratio than are others of the same class elsewhere, but that the more severe forms of venereal affections are commoner amongst them, and those whom they infect, are facts requiring no substantiation from ourselves. But it appears also, that in the opinion of some well qualified to judge, venereal diseases are prevailing in some densely-populated manufacturing districts, "to an extent barely credible," and that, on examining the recruits for the militia, they were found "to be diseased to the extent of twenty-five per cent." Surely, then, both as a matter of economy to the state, as a right precaution to be fairly expected from the latter in relation to the bodily health of a large number of public servants, and as, in combination with these advantages, the power of offering curative relief to numbers of diseased and miserable women, capable of, and indeed constantly, unintermittingly spreading a loathsome and severe malady, the suggestion of Dr. Rose is worthy of the serious consideration of the government.—*Lancet*.

#### ROYAL COLLEGE OF SURGEONS—MERIT REWARDED.

AT a meeting of the students of the Royal College of Surgeons on Thursday last, George H. Hyndman, Esq., in the chair, Mr. John Evans, who filled the situation of janitor for a period of twenty-seven years, was presented with a valuable silver watch, gold chain, seals, &c., as a testimonial of approval of his excellent conduct in his situation, and to express their satisfaction at his promotion to a higher situation in the same institution. The watch bore the following inscription:—"Presented with gold chain, seals, &c., by the students of the R.C.S.I. to J. Evans, in testimony of their approval of his conduct in his late situation. 1853." We are glad to see by the above that merit in the humble rank of life is not always overlooked. The college has done well in promoting a good and efficient officer; and the presentation of this testimonial from the students is one that must prove gratifying to every man in whatever clime he may now be placed, who studied in our national school during the seven-and-twenty years of Evans's connexion with the institution. We have no doubt but many of them, like ourselves, would gladly have added their testimony to the worth and attention of Evans, had they known that this testimonial to merit was in contemplation.—*Freeman's Journal*.

#### MEDICAL VIRTUES OF GREEN GOOSEBERRIES.

I BOUGHT a bottle of preserved gooseberries from one of the most respectable grocers in this town, and had had its contents transferred into a pie. It struck me that the gooseberries looked fearfully green when cooked; and on eating one with a steel fork, its intense bitterness sent me in search of the sugar. After having sweetened and mashed the gooseberries with the same steel fork, I was about to convey some to my mouth, when I observed the prongs to be completely coated with a thin film of bright metallic copper. My testimony can be borne out by the evidence of three others, two of whom dined at my table.—*Letter in Lancet*.

## CURE OF NEURALGIA OF THE FACIAL NERVE

By S. LAURENZI.

D. CECCHINI, aged 50, of sanguine temperament, suffering from neuralgia for about two years, and had tried various remedies, general and local; such as ointments containing chloroform, cyanide of potassium, &c., without any benefit, was admitted into the surgical wards at the Hospital St. Jacques at Rome, under Professor Olivieri, who decided on excising the affected nerve. The operation was performed by S. Laurenzi in the following way:—A vertical incision was made from the zygoma to the angle of the jaw, the cellular tissue and fascia divided, and portion of the gland dissected. The cervico-facial division of the nerve (which appeared to cause most pain) was seized by a forceps and excised to the extent of two or three lines. It may be well to add, that at the end of thirty days the neuralgia had not appeared, nor paralysis of the muscles supplied by the nerve.—*Raccoglitori Medico.*

## ON THE EMPLOYMENT OF ICE POULTICES.

M. SANDRAS relates the following cases where the good effects of this application were manifest. The first was one of glossitis, in a boy six years of age, complicated with aphthous ulcerations of the mouth, the tongue having the appearance of being double. The ice poultices and borax gargle cured this affection in a few days.

The second was one of typhoid fever of the adynamic form, which was treated by saline purgatives and poultices composed of linseed meal and pounded ice. The heat of the abdomen and tympanitis were such, that the ice melted in five minutes after being first applied. The patient kept them on for half an hour, then for three quarters of an hour, and afterwards for one hour. On the sixteenth day the ice did not melt for two hours, and the applications became intolerable, a symptom that shows it ought to be stopped, which was done accordingly.—*Presse Méd. Belge.*

## REDUCING THE SALARIES OF POOR-LAW MEDICAL OFFICERS.

A PARLIAMENTARY paper has just been printed respecting the Tewkesbury Union. The board of guardians carried resolutions to reduce the salaries of the medical officers, on account of the "cheapness of provisions." The officers appealed to the Poor-law Board, and the reasons were required from the guardians that induced them to pass the resolutions. They urged that the value of agricultural produce had been diminished at least 30 per cent., that the rates had decreased, and that food was cheap. The Poor-law Board replied, that they had "never recognized the principle that the price of the articles and of the produce referred to are to be the criterion by which the amount of salaries ought to be estimated and regulated, or that such salaries should be liable to vary as the price of food fluctuates." The Poor law Board thought that no sufficient reason had been assigned for the reduction, declaring that the fixed salaries of the medical officers remunerated them only for their ordinary duties, and the board did not see that sufficient grounds had been adduced for diminishing the salaries of the officers referred to in the resolutions of the guardians.

A SURGEON COMMITTED FOR MANSLAUGHTER.—A very painful sensation has been created in Bedford, by the committal, under the following circumstances, of Mr. Robert Hicks, the highly respected surgeon of Toddington. It appeared, that as Mr. Hicks was passing the house of a Mr. Ward, he was called in, and requested by Mrs. Ward to examine her son's leg, which she suspected had been severely injured by a fall. After examining the leg, Mr. Hicks said that the small bone was broken, and applied to it a diachylon plaster, bandaging the limbs—the mother having told him he could not set it that night. The child, who was four years old, was brought to him the following morning, when he substituted pasteboard for the plaster. The child getting worse the next day, Mr. Hicks, jun., attended, and expressed a fear that a gathering was taking place under the knee; whereupon he and his father consulted, and applied a bread poultice to the whole limb

That evening Mr. Benson, surgeon, was sent for, but he could do nothing for deceased, who died that night. Mr. Benson, before the coroner's jury, stated, that he performed the autopsy, and found no fracture of the leg, but that under the knee-joint, some matter, which filtrated through the muscles of the leg, had escaped. In his opinion, death resulted from congestion of the brain, produced by the pressure of the bandage. Mr. Hicks' treatment was injudicious. Mr. Thompson, surgeon, corroborated Mr. Benson. It further appeared, that Mr. Hicks gave a certificate of death, stating that deceased died from an inflammation of the bowels and knee-joint. The jury returned a verdict of "Manslaughter" against Mr. Robert Hicks, who was accordingly committed to jail, under the coroner's warrant. [The above probably contains many inaccuracies; but there can be no mistake as to the absurdity and injustice of the verdict.]—*Association Journal.*

## ADMINISTRATION OF PHOSPHORUS.

It has long been a desideratum in medicine to find some safe mode of administering phosphorus. At first I supposed that this would be attained in the new amorphous phosphorus; but from experiments on animals, I find this substance to be without either the deleterious or the active physiological properties of the ordinary substance. I have given phosphorus lately in the following ways: first, in the form of a solution in chloroform; secondly, in cod-liver oil. Chloroform dissolves about one-fourth of its weight of phosphorus; and the solution is not inflammable. I have given four or five minims of this solution, shaken up with a drachm of ether in a wineglassful of port wine, twice a day, with great benefit in rallying the forces of the patient, as I fancied at least, in cases of typhoid fever. The solution in the oil is made by cutting the phosphorus into chips, and putting it into a bottle of the oil, in the proportion of half a grain to the ounce, then immersing the bottle in hot water, and with a little shaking, solution is easily effected. I think I have seen this beneficial in strumous cases. I am still investigating the subject, and beg to suggest it to others also.—*Dr. R. M. Glover in Lancet.*

M. W. HANLON, M.B.

MILK IN ABDOMINAL TYPHUS.—Through the French and Belgian journals, we learn that Dr. Thielmann, of St. Petersburg, administers from two to four tumblers of milk to his patients affected with abdominal typhus, in all stages of the disease—even when they are in a state of insensibility. He believes that this aliment is not only well borne, but is assimilated, and that it gives a power of resisting the disease. More than one patient, he says, who had been given over as hopeless, has been saved by the milk treatment: and he avers that the inconveniences which often follow the use of broth, and similar articles of diet—such as delirium, meteorismus and diarrhœa—never occur when milk is substituted for them.—*Association Medical Journal.*

## GOOD NEWS FOR PLACE-HUNTERS.

NAPOLEON III. seems, according to the recent reports, anxious to conciliate the medical profession, by appointing an unusual number of physicians and surgeons to the imperial court, with liberal salaries. Of these, it is said, there will be at least twenty, having from 6000 to 8000 francs (£240 to £320) per annum, besides the honour of being attached to majesty. Whatever may be the motives influencing the Emperor in these proceedings, the large amount of money which will be thus distributed amongst professional men in Paris, must prove very opportune to various individuals, since no class has suffered more, by late revolutions and tornadoes, than members of that body. This example is worthy of imitation elsewhere; and if the contemplated appointments are conferred only on hard-working and scientific practitioners, every fortunate holder will be materially benefited, whilst their brethren must feel satisfied by the prospects here held out to future candidates.—*Lancet*.

## DR. BELLINGHAM ON ANEURISM.

Lately published, 12mo, price 4s.,

## OBSERVATIONS ON ANEURISM AND ITS TREATMENT BY COMPRESSION.

By O'B. BELLINGHAM, F.R.C.S.I.,

One of the Surgeons of St. Vincent's Hospital.

"In our opinion, he has conferred a signal benefit upon the art of surgery by his improvement of the mode of employing pressure, and upon the science by his ingenious and philosophic exposition of its operation."—*Medico-Chirurgical Review*.

"Dr. Bellingham has ably advocated the cause of compression as a highly useful and successful mode of treating numerous cases of external aneurism."—*Lancet*.

"The very excellent and practical essay lately published by Dr. Bellingham, to which we would refer our readers, as containing a most masterly account of the treatment of aneurism by compression."—*British and Foreign Medical Review*.

"Dr. Bellingham's little work is well worthy of attentive perusal, and we feel a confident hope that henceforth another formidable operation (as ligature of the femoral vessel even under favourable circumstances unquestionably is) may in a great majority of instances be avoided."—*American Journal of the Medical Sciences*.

"I conceive that for a just exposition of the principles on which that mode of treatment should be conducted, as well for some valuable improvements in the mode of procedure itself, the surgical profession is mainly indebted to you."—*Philip Crampton's Letter to the Author*.

London: John Churchill, Princes-street, Soho.

Dublin: Fannin and Co., Grafton-street.

## THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY.)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System.

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

## DR. JACOB ON DISEASES OF THE EYE.

Just published, 8vo, pp. 96, price 2s. 6d.,

## A TREATISE ON CATARACT;

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F.R.C.S.,

Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5s.,

## THE INFLAMMATIONS OF THE EYEBALL:

Being a Treatise on all the Species and Varieties of Iritis.

Dublin: Fannin and Co., 41, Grafton-street, or the Office of the MEDICAL PRESS, 15, Molesworth-street. London: John Churchill, Princes-street, Soho.

## TO THE MEDICAL PROFESSION AND THE PUBLIC.

GEORGE OLDHAM AND CO.,

## APOTHECARIES AND CHEMISTS,

in availing themselves of the present opportunity to return their grateful acknowledgments to their Friends for the support which they have hitherto received, and which they will regard as a fresh motive for exertion, beg leave to announce that they have taken the

ROYAL MEDICAL HALL, 64, DAME-STREET,

(Late Bewley, Owen, and Co.'s.)

which they will henceforward conduct in connexion with their MEDICAL HALL, 107, GRAFTON-STREET.

In notifying the above change in the management of the Royal Medical Hall, G. O. and Co. can assure the present Friends of that establishment, that the same scrupulous attention and care has been paid to the selection and preparation of their Medicines and other articles, which has gained them such extensive support in their Medical Hall, 107, Grafton-street; and they hope their arrangements to ensure accuracy, neatness, and despatch, combined with moderation of charges, will merit the approbation of those who may entrust them with their commands.

The Royal Shaving Cream, Essence of Ginger, Matico, Tooth Powder, Essence of Rhubarb, Ginger, and Chamomile; and other preparations heretofore made and sold at the Royal Medical Hall, can now be had at either Establishment.

107, GRAFTON-STREET,

AND

64, DAME-STREET, DUBLIN.

## TO SURGEONS, DISPENSING CHEMISTS, ETC.

SULPHATE OF QUININE, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, capsuled, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.

October 23, 1852.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

Wednesday, January 26, 1853.

CASE OF ORGANIC DISEASE OF THE HEART—ANGINA PECTORIS—DEATH DURING A PAROXYSM—WITH REMARKS.

By O'B. BELLINGHAM, M.D.

Dr. BELLINGHAM said he would take that opportunity of exhibiting to the members of the Society the heart of a man who had died in hospital during the last summer in a paroxysm of "angina pectoris." He would first read the notes of the case, and conclude with some remarks upon angina.

The patient, Daniel Kavanagh, a labourer, aged 40, was admitted into St. Vincent's Hospital, under his care, July 15, 1852. He stated that he has been employed for the last twenty years in the works on the River Liffey, under the Ballast Board, in which he has been much exposed to cold and wet, and the labour had been extremely severe.

He always enjoyed good health until about six months since, when he was seized with severe pain on running, which compelled him to stop, when it subsided. Since that period he has suffered frequently from this pain on using much exertion at his work, or on walking quickly. The pain was at first a catch or stitch, and was referred to the lower part of the sternum; in subsequent attacks it extended to the upper edge of the sternum, and passed through the thorax to the left scapula. A month ago, it was experienced, in addition, in the left shoulder, arm, and forearm, reaching to the palm of the hand. He describes the pain as having a severe, burning character, and he refers it principally to the lower part of the sternum, from which it extends to the upper edge of this bone, and passes through the chest to the left scapula. The pain in the left shoulder and arm, he says, is a dead or numb pain. He suffers no pain as long as he is at rest; but if he walks quickly, or exerts himself at his employment, the pain sets in, and subsides again when he rests. He is a tall, muscular, and healthy-looking man, and with the exception of this pain and palpitation, he enjoys good health.

On examining his chest, there is no unusual impulse of the heart; the pulsation of the carotids is visible, but not remarkably strong. On auscultation, a murmur is audible at the period of the second sound of the heart, which is soft and prolonged, loudest a little to the sternal side of the left nipple. Over the upper bone of the sternum, a double sawing murmur is distinctly heard.

July 17th: On entering the ward this morning, I found the patient up and dressed, and in his usual health. I desired him to undress and to get into bed; in the mean time I was occupied with a patient in the next bed. On coming to him he seemed to be suffering extreme pain; he was writhing about in bed; the countenance was pale and ghastly; his face and chest were wet with perspiration, just as if water had been poured on him; the hands were cold, and the pulse was almost absent at the wrist. Stimulants were immediately freely given, consisting of subcarbonate of ammonia in camphor mixture, with ether and Hoffman, hot brandy and water, &c. A mustard cataplasm was applied to the præcordial region, and a warm jar to the soles of the feet. The pulse improved slightly, and the pain appeared to diminish; he soon began to complain of the pain of the mustard, and he requested it to be removed. On applying the stethoscope to the præcordial region, the heart's action was feeble and irregular, and no bruit was audible. The improvement, however, was very transient, he continued to writhe about in bed, sometimes turning upon the face, sometimes upon the side, particularly the right. The perspiration continued, and his shirt was quite wet through. He begged for something to be done for his relief, as he said he could not long endure the pain, which had a burning character, extending from the sternum through the chest. He died in somewhat less than two hours from the commencement of the attack, the pupils having become greatly dilated immediately previous.

*Post-mortem Examination.*—The examination was made twenty-one hours after death. On opening the chest, old and close adhesions were found between the layers of the left pleura; the outer surface of the pericardial sac had likewise been implicated, as it was firmly adherent to the

left pleura, and partially to the right. The pericardial sac itself was so closely in contact with the heart, that it could not be raised from it, and it seemed at first as if they were adherent. This was not, however, the case; it arose from the distension of the chambers of the heart, which was so great that the pericardial sac was stretched to the utmost, and rendered so tense that it could not be raised from the heart with a forceps.

When the pericardial sac was laid open, the heart much enlarged came into view; its apex was deep in the chest, the adhesions of the pleura on the left side preventing it from approaching the parietes. A larger amount of fat than natural existed upon the surface of the heart, which filled up the grooves and extended beyond them. A white patch of an irregular shape occupied the anterior surface of the right ventricle; another was seated upon the appendix of the right auricle, and smaller opaque patches extended along the course of the coronary veins, and partially connected the serous surface of the base of the auricles with the base of the ventricles.

All the cavities of the heart, the vena cava, and the pulmonary veins, were distended with blood, which was perfectly fluid. When emptied of blood, the heart weighed twenty-eight ounces. The part principally enlarged was the left ventricle, the walls of which were increased in thickness, measuring above an inch at the thickest part, which was near the base; while at the apex it was not above half an inch; the cavity of this ventricle was also considerably dilated. The aortic valves were thickened at their free margin, particularly the valve between the orifices of the coronary arteries; they were likewise opaque and rigid, and imperfectly closed the orifice, permitting regurgitation.

The ascending portion of the arch of the aorta was dilated, its lining membrane extremely rough and irregular, presenting every variety of adventitious deposit, the coats being thinned in some places and thickened in others. The other parts of the valvular apparatus of the heart were not diseased.

#### OBSERVATIONS.

Angina pectoris has been heretofore always described as a distinct disease. The earlier writers upon the subject supposed it to have some mysterious connexion with ossification of the coronary arteries; others, that it depended on excessive deposition of fat upon the heart. Modern pathologists having failed not unfrequently to discover either of these morbid changes, and seeing the suddenness with which it supervenes and subsides, refer it to *spasm* of the heart; while others, again, looking more to the character and intensity of the pain, regard it rather as a form of *neuralgia*, and describe it under the name "*Neuralgia of the Heart*."

I do not think sufficient evidence has been adduced to entitle angina pectoris to be regarded as a distinct disease; neither do I think it necessary to call in the aid of spasm or neuralgia, when there are circumstances in its clinical history and pathology which seem to be quite capable of explaining all its phenomena independent of either. Thus, angina, in a well-marked form, is not seen except in cases of organic disease of the heart; and as a general rule, it is not observed even in these, unless something occurs either to disturb the action of the heart or to hurry the circulation.

The *immediate cause* of angina pectoris appears to me to be a sudden impediment to the *coronary circulation*, particularly to the return of the blood by the coronary veins, itself in general the result of a temporarily over-distended state of the chambers of the heart, and an inability in them to empty themselves, whether owing to weakness of the muscular tissue of the parietes of the left ventricle, or to other causes. For instance, if the cavity of the left ventricle is considerably dilated, or its walls are attenuated, or softened, or have undergone fatty degeneration, the contractile power of its muscular tissue will be impaired in proportion; and if the circulation happens to be suddenly hurried, or the heart's action to be suddenly disturbed, the cavity of this ventricle might become so much distended as

to be unable to contract upon its contents, which would be immediately followed by distension of the auricle on that side, and if relief is not quickly experienced by distension of the right chambers of the heart.

It is scarcely necessary to say, that in a normal state of the circulation, all the chambers of the heart are never full of blood at the same moment. When the ventricles are filled, the auricles are comparatively unfilled, and *vice versa*. Here, however, we would have a suddenly distended state of the chambers on both sides of the heart at the same moment. From the position of the coronary vessels in the grooves of the heart, they cannot, we know, suffer compression during the alternate movements of the ventricles and auricles; but if the auricle and ventricle upon each side of the heart are distended at the same time, these vessels, but particularly the veins, must suffer compression, by which their circulation will be impeded; and the great coronary vein, in addition, may be prevented from freely emptying its contents into the right auricle, in consequence of the distended state of this cavity.

We know, likewise, that the normal capacity of the pericardial sac is but little greater than that of the heart in its ordinary state of distension; and that this membrane is composed of tissue which does not *suddenly* yield. The parietes of the heart would, therefore, under the circumstances that I have described, be placed between two compressing forces—an undue amount of blood in the chambers of the organ, and the unyielding pericardium upon the outside. The effect of this compression of the heart's tissue would necessarily be to impede still further the coronary circulation, and to clog still more the movements of the organ, and the condition of the heart would be somewhat analogous to that in which a large amount of fluid was *suddenly* effused into the pericardial sac, from rupture of a vessel or other cause.

The organic lesions of the heart most likely to be attended with angina would, therefore, be a condition of the aortic valves permitting free regurgitation, with a rigid, dilated state of the ascending portion of the arch of the aorta, which permits the blood from the large vessels to regurgitate into it, combined with either—

1. Dilatation of the cavity of the left ventricle; or,
2. Attenuation of the parietes of the left ventricle; or,
3. Softening or fatty degeneration of the muscular tissue of this ventricle.

For instance, when the aortic valves permit free regurgitation, there is at each ventricular diastole a reflux of blood from the aorta into the ventricle at the same time that the current is entering it from the auricle; the left ventricle consequently is unable to empty itself, the state of distension in which it is kept leads to permanent dilatation of its cavity, which tends still further to embarrass the circulation by enfeebling the ventricle, and diminishing its power of expelling its contents.

It has been shown by Hales, that "each square inch of the surface of the interior of the ventricles has a pressure upon it during the systole equal to about four pounds," and "as the resistance which the heart has to overcome in contracting, is, according to hydrostatic laws, in proportion to the extent of the inner surface of the cavity at the commencement of the systole," if the cavity of the ventricle is dilated, more force will be required to enable the ventricle to expel its contents; and the greater the amount of the dilatation the less able will the ventricle be to overcome the resistance. In such a state of the aortic valves, and in such a condition of the ventricular cavity, if the parietes of the left ventricle are, in addition, attenuated or softened, the ventricle will be still less capable of overcoming the resistance, and a very trifling muscular exertion, or a sudden mental emotion, may lead to over distension of its cavity, followed by distension of the other chambers of the heart. If, at the same time, the arch of the aorta is dilated, and its coats are rigid and inelastic, permitting the blood from the large arteries which come off from the arch, to regurgitate into it, the coronary circulation will be necessarily greatly impeded, and a paroxysm of angina will be the result.

Any one of the foregoing morbid conditions of the heart may be present, or two or more of them may be combined, without angina necessarily occurring; indeed, as long as the circulation continues tranquil, and as long as the left ventricle is able to get rid of the blood which enters its cavity, the latter cannot become over-distended. If, however, the heart's action is disturbed by some sudden mental emotion, or other cause; or even without this occurring, if the stomach is loaded with indigestible food, and it and the intestines are distended with flatus, by which the cavity of the chest is encroached upon, and the heart's movements are impeded, a paroxysm of angina may be the result. Hence, in persons who have had previous attacks, it is liable to supervene during sleep, when it may be the result of a frightful dream, disturbing the heart's action; or of considerable distension of the stomach by flatus, impeding the movements of the organ.

Dr. Forbes,\* in his able article on the subject, has shown that *plethora* is a very common complication of angina; a state which, if combined with a weak heart, would give a further predisposition to the attack. Thus, "the subjects of angina (Dr. Forbes observes) are mostly of the male sex, above 50 years of age, and a great majority of them belong to that class of persons who are enabled to indulge in full living, without the necessity of undergoing severe bodily labour." Again, "gout is a very frequent disease in persons subject to angina, and obesity is extremely common." "The very existence, too, of angina tends (he adds) to produce plethora if it did not previously exist; a sedentary life and abandonment of all active bodily exertions, are almost inevitable consequences of the disease."

It may, perhaps, be objected that the foregoing explanation of the cause of angina is insufficient to account for the peculiar pain which accompanies a paroxysm. I cannot, however, imagine any state more likely to be attended by intense distress, anxiety, and suffering, with a sensation of impending dissolution, than such as I have described, where the chambers of the heart are immoderately distended, the coronary circulation temporarily obstructed, the heart's movements clogged or impeded, or its muscular tissue compressed.

Angina pectoris, in its most marked form, is almost peculiar to advanced life; thus, of 84 cases recorded by Dr. Forbes, 72 were above 50 years of age, and only 12 under that age. The reason of this is sufficiently obvious; the morbid conditions upon which it depends are, in some measure, limited to advanced life. Again, when a person has been once the subject of angina, subsequent attacks are very likely to ensue if the exciting causes come into operation, because the diseased states on which it depends are irremediable. Lastly, angina is rare in the female compared with the male, because the diseased state of the aorta so frequently associated with it, is very seldom met with in the female; indeed, regurgitant disease of the aortic valves itself, is less frequent in the female than the male.

In conclusion, then, I would say, that angina pectoris ought to be regarded rather as a *symptom* of organic disease of the heart than as a distinct form of disease; in fact, what dyspnoea is to the lungs, angina appears to be to the heart, and it might without impropriety be termed the *dyspnoea of the heart*. Thus both are met with in very variable degrees of intensity; both have sometimes apparently almost purely a spasmodic character, and both are often the result of mechanical causes—in the one case, of some impediment to the free passage of air into or out of the lungs; in the other, of an impediment to the circulation in and through the heart. It would, indeed, in my mind, be almost as absurd to class dyspnoea apart, and describe it as a distinct affection, as it is to make angina a separate disease. As dyspnoea may arise under variable and opposite states of pulmonary disease, so angina may ensue in different forms of cardiac disease. We can, likewise, easily understand, from what precedes, that if the paroxysm of angina is slight, it may pass off spontaneously, or under the influence of stimulants and other appropriate

measures, the heart may be enabled to get rid of the blood which distends its cavities; while, if the paroxysm is severe and continued, complete arrest of the coronary circulation may ensue, followed necessarily by cessation of the heart's action and the death of the patient.

The conclusions which I would draw from what precedes, are—

1. That angina pectoris is to be regarded as a symptom of disease of the heart, not as a distinct affection.
2. That it does not occur except where organic disease of the heart, generally of long standing, exists.
3. That its connexion with spasm, or neuralgia, is more than doubtful.
4. That its probable cause lies in impediment to the coronary circulation, particularly to the return of the blood by the coronary veins.
5. That the diseased states of the heart in which it is most liable to ensue, are a condition of the aortic valves permitting free regurgitation, with a rigid dilated state of the ascending portion of the arch of the aorta, combined with either dilatation of the cavity, or attenuation, or softening of the parietes of the left ventricle.
6. That even in these diseased states, angina may not occur unless the heart's action is suddenly disturbed, or its movements are clogged, or impeded by some mechanical cause.

The PRESIDENT observed that the communication was one of much interest, and he would be glad to hear the opinions or experience of the members present upon the subject. Could any gentleman mention one or more cases where angina pectoris had existed without some or any of the morbid signs included in Dr. Bellingham's theory?

Dr. H. KENNEDY said there was one point which, it struck him, was not easily reconcilable with the views advanced by Dr. Bellingham—namely, that diseases of the heart and great vessels were exceedingly common; whilst angina pectoris was a comparatively rare affection—certainly, not by any means of such frequent occurrence as disease of the heart. He was borne out in what he said by another fact; namely, that there were many instances on record in which the affection called "angina pectoris" had been entirely got rid of. He found in the course of his readings many cases in which persons, who had suffered severely from angina pectoris, had completely recovered—a fact which was totally irreconcilable with the idea that it depended in any degree on organic disease of the heart; for there was no reason to believe that when organic disease of the heart had once fairly commenced, it could be remedied by treatment. He did not scruple to confess that he had always felt disposed to regard angina pectoris as connected with some particular form of dyspepsia. Certainly, whatever relief was experienced by the patients he had met with, appeared to depend on the attention paid to their general health, by keeping the stomach in order, and using a proper discrimination in the selection of food, &c. Under these circumstances, he had known many cases to be ameliorated, though none, he must admit, were completely cured.

Dr. BENSON said that he was particularly struck with the interesting paper which Dr. Bellingham had brought under their notice on that occasion. He confessed that some objections did occur to him whilst it was in course of being read to the Society. The objection raised by Dr. Kennedy, however, did not appear to him to have much weight; for although in a large number of instances of organic disease of the heart, angina pectoris did not present itself, yet when it did make its appearance, it might be under the circumstances mentioned by Dr. Bellingham; namely, when there was over-distension of the cavities of the heart, and as a consequence of this state of things, an obstruction of the circulation through the coronary vessels. If the case was one of organic disease of the heart, and angina pectoris supervened, in that case, although the organic disease might not be curable, yet the state of things which gave rise to the angina pectoris might be got rid of by judicious treatment. A general attention to the patient's health might so far improve the circulation

\* Cyclopædia of Practical Medicine.

through the heart as to remove those secondary causes, whatever they were, that produced the angina pectoris, although the original organic disease might still remain. Particular instances, therefore, like those mentioned by Dr. Kennedy, in which dyspepsia appeared to be the exciting cause, would not suffice to overthrow the theory advanced by Dr. Bellingham. There were, no doubt, some difficulties in the way of accepting that theory; but nevertheless, on the whole, it appeared to him to be much more satisfactory than any other explanation he had met with. Against the supposition that it was a neuralgic affection, there was this weighty fact—namely, that it was much oftener found in males than in females. Dr. Heberden had shown that out of one hundred cases, only three were females. This fact was strongly opposed to the notion of its being a neuralgic affection. The opinion that it was a spasmodic complaint was liable to the very same objection. Besides, it was difficult to conceive how a spasm could act in such a manner as to leave the circulation so little disturbed as it occasionally is. In one of the severest attacks he ever saw, the pulse was not very much disturbed. The same thing had been noticed by Heberden. This indeed was an objection to Dr. Bellingham's theory as well as to the spasmodic. Another objection he would name to Dr. Bellingham's theory was, that an opiate often gave relief—a fact scarcely reconcilable with his theory, but quite consistent with the spasmodic. And again, another objection occurred to him—namely, that in cases of emphysema with bronchitis, where the heart is greatly congested and usually becomes enlarged and softened, where the conditions best calculated to bring on a fit of angina, according to Dr. Bellingham's supposition, exist to perfection, there was hardly ever seen such an event. Dr. Bellingham made objections to the use of the term angina, which he (Dr. Benson) did not consider valid. It is true it was only the name of a symptom; but it was extremely convenient to have a word to mark a symptom of so peculiar a character, under which other symptoms might be grouped; more especially as one could not always tell the organic disease which gave rise to it. The same reasons induce medical men to use the words "jaundice," "dropsy," and "fever," to designate conditions which generally depend on some organic affection that could be pointed out. The term "asthma," was in constant use, although asthma was but a symptom depending on certain circumstances; and therefore there was no impropriety in using the phrase "angina pectoris" in the sense in which it is employed. The theory advanced by that gentleman, which he believed to be original, went farther than any other theory he was acquainted with, in explaining the phenomena of this peculiar affection, and he thought the profession ought to be much obliged to Dr. Bellingham for bringing the matter under the notice of that Society, with a view of eliciting discussion upon so interesting a subject.

Dr. H. KENNEDY said he just recollected that one of the cases to which he had referred was cured by means of issues. In one or two cases, four or six ounces of blood, taken at the time, was found to be one of the best modes of alleviating the fit, the usual stimulants being also administered internally.

Dr. BENSON—That would favour Dr. Bellingham's theory of the existence of plethora.

Dr. MORGAN referred to the case of a medical student, who was under the care of Sir Henry Marsh for a severe attack of angina pectoris. This gentleman had suffered severely and repeatedly from such attacks, and he was under an impression that, in this case at least, Sir Henry Marsh had attributed the angina pectoris to congestion. An issue was tried in this instance with some success, and for some time past the patient had not had a return of the complaint.

Dr. BENSON knew the case to which Dr. Morgan alluded, and could say that he examined the gentleman on several occasions, and that neither he nor Sir Henry Marsh could detect organic disease of the heart, though it was pretty certain that a good deal of fatty matter was deposited on the latter—a condition referred to by Dr. Bellingham as

sometimes accompanying angina pectoris. A great many of the older writers insisted that no organic disease could be found in some of the cases of angina pectoris which came under their observation. He should like to know in what state was the blood in the heart of Dr. Bellingham's patient?

Dr. BELLINGHAM—Perfectly fluid. Both the vena cava and the pulmonary veins were likewise distended with fluid blood.

Dr. BENSON believed such was generally the case.

Dr. H. KENNEDY—In the case I examined there was also great distension of the cavities, and a large accumulation of fat about the heart.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE PARTICULARS OF TWO CASES OF POPLITEAL ANEURISM TREATED BY COMPRESSION, WITH SOME GENERAL OBSERVATIONS ON THAT PLAN OF TREATMENT.

By BENJAMIN PHILLIPS, F.R.S.,  
Surgeon to the Westminster Hospital.

THE author's objects in laying this paper before the Society, are to procure a permanent record of perhaps an unique case—one of popliteal aneurism on each side in a female—and to obtain a deliberate consideration by the Society of the treatment of aneurism by compression. As a proof of the necessity for further deliberation on this subject, he refers to the different estimate of the general applicability of the remedy in Dublin, London, and Edinburgh. The author alludes to the want of some tribunal before which important questions should be brought and discussed, as is done in the Academy of Medicine at Paris, where a subject such as the present would be referred to a committee to report upon, and a discussion would take place on the report.

Catherine C—, aged 39, a market-woman, tall and gaunt, was admitted into the Westminster Hospital on December 3, 1851, with a pulsating tumour in the right popliteal space. She had observed a stiffness about the right knee about two months before admission. She followed her occupation, and carried heavy loads on her head; but gradually the part became more painful, especially after her day's work. Three weeks before her admission, in getting into a cart the limb was stretched, and she felt something give way in the ham. The pain suddenly increased, and in two days extended to the ankle. Her habits of life were unfavourable; she was a confirmed gin-drinker, and she laboured under great nervous excitement and apprehension. The heart's action was most tumultuous, but no signs of disease could be detected along the course of the large internal vessels. There was a pulsating tumour in each popliteal space. That on the right side commenced in Hunter's canal, a little above the point where the artery enters into the popliteal space, and extended beyond the middle of that space. It could not be emptied by any amount of pressure. The tumour on the left side was situated lower down in the popliteal space; was smaller, and with less violent pulsation. The treatment was at first directed to her general condition; it consisted of a moderate diet, with abstinence from fluids; ice and ice-cold water were applied to the tumour. Under this plan she improved; and at the end of a fortnight it was determined to try the effects of moderate pressure on the side of the larger tumour. From her alarm at the sight of an instrument invented by the author, it was thought prudent to commence proceedings by means of a simple ring tourniquet, the pad being fixed near the apex of Scarpa's triangle. It was screwed tight enough to cause the pulsations to become imperceptible to the touch. At the end of two hours the pain was so great that it became necessary to remove the pressure; and in place of the tourniquet, a Signorini's compressor was applied at the groin. It slipped, however, after nearly three hours, but was re-applied for the night; but in the morning it was found to have slipped again. During the day and night moderate pressure was kept up by means of the ring tourniquet, the situation of which was altered from time to time, and this

was continued during the succeeding day. The pulsation of the tumour had evidently lessened, the knee looked shining, and the leg was slightly œdematous. During the night the author's compressor was used. Pressure was continued during the following day and night; the ring-tourniquet was used, and with slight intervals the pressure was continued for seven days longer, when the tumour was carefully examined; it felt more solid, and no whiz could be detected when all pressure was removed. The pressure was more or less steadily applied for twelve days more. At this time there was more fulness about the knee and ham; no whiz could be heard; but there was a general elevation of the mass, synchronous with the heart. After two day's interval, pressure was again applied, and continued at intervals for eleven days. It was believed, however, that the treatment had failed, and that the aneurism had become diffused; and as a last chance, ligature was applied. She died on the seventeenth day after the operation; and, on examination, a clot was found extending from the ligature to the aneurism. The posterior ligament of the knee-joint was ulcerated, and the cavity of the joint contained sanguineo-purulent fluid. The aneurism in the left side appeared to consist of a fusiform dilatation of the artery, and contained concentric laminæ of coagulated blood. There was a large aortic aneurism commencing below the origin of the cœliac axis. The aorta and many other arteries presented extensive fatty degeneration.

George S——, aged 31, a navigator, admitted July 8th, with a popliteal aneurism of the size of a turkey's egg. It had begun six months before from a strain. Six weeks after this, he observed a "knot" in the bend of the knee, which gradually increased to its present size. His health is good, and the circulating system tranquil. The characters of aneurism were very marked, and when firm pressure was applied on the artery at the groin, the tumour disappeared. It was found that he had been treated by compression at the Reading Hospital, and the author was furnished with particulars of the case by Mr. Bully; from which it appeared that pressure was applied for three weeks by which the tumour became less, and lost its elastic feel. It was noticed that at night, when the pressure was entirely removed the pulsation ceased; but that when it was reapplied the pulsation returned. Obstructive pressure was now applied for some time, but the man became impatient, and refused to allow any treatment. He was consequently discharged.

Although it appeared that a fair trial had been made, yet the author was induced to repeat the compression, and Dr. Carte saw the case, and aided the author with his instrument. The author here proceeds to describe the instrument. It was applied the 14th of July, and no pulsation could be detected in the tumour, which was completely emptied. The kind of pressure was varied as well as the situation. In three days it was noticed that the tumour could no longer be emptied, and that it contained coagula. The pressure was now continued; and, on the ninth day, the tumour was quite firm, and there was no pulsation in it. Since that time he has remained quite well.

After commenting on the different effects noticed at the Reading Hospital, and under his own treatment, the author adverts to the fact, that authorities are still found in opposition to the treatment of aneurism by compression. It must, however, be judged of by its results; and if it be shown that more cases are cured by it than by ligature, it will ultimately be preferred. Mr. Syme's statement, that he has tied the femoral twenty times without bad results, does not agree with the experience of this operation in the hands of others; and it appears, by reference to cases, that the failures amount to between one-third and one-fourth of the whole. The treatment by compression is far more favourable, its failures not exceeding one-fifth of the whole; and even when it fails, the patient's life may be saved. The question, whether there are any objections to this mode of treatment so serious as to make the surgeon hesitate to employ it, is answered by the author in the negative; and he objects to Mr. Syme's description of the time employed and the pain to be endured under it, as not a fair statement

of the case. He admits that cases have occurred where great suffering has attended the treatment by compression, but conceives that this is unnecessary, and is not the common result. It originated in a mistaken notion that it was necessary to stop the current of blood entirely in order to effect a cure. Mr. Todd did not think excessive pressure necessary; but those who followed him, for some time acted on the opinion that what the ligature does must be done by compression. But it has been proved that an aneurism may be cured although the whole supply of blood be not completely cut off, even when the ligature has been used. The author maintains, then, that the surgeon is justified in adjusting the pressure to the enduring powers of the patient, rather than to the almost complete extinction of pulsation in the sac, provided the pressure be sufficient to produce a decided diminution in the force of the pulsation. As to the most eligible point for applying the pressure, he thinks it should be where it can be best borne, and where it occasions the smallest amount of inconvenience; and he does not think it of consequence that the pressure should be applied above the profunda. It is important, however, that the return of blood by the veins should be as little as possible interfered with, and for this reason he believes that the immediate neighbourhood of Poupart's ligament is the most desirable situation, while at the same time a smaller amount of pressure is necessary at that point. The author maintains that the pressure should be applied gradually, and not suddenly, so as to admit of the enlargement of the collateral vessels; and he thinks it is clearly established that continuous pressure is not absolutely necessary. The author sums up by saying that he is justified in asserting that pressure should be applied at points where it can be best borne, provided it be not too far removed from the sac; that, if possible, it should be so applied as not to prevent the return of venous blood; that it should be strong enough to produce a sensible influence on the strength of the pulsation in the tumour; and that it may be intermitted to a sufficient extent to make the treatment tolerable to the patient.

#### CASE OF POPLITEAL ANEURISM CURED BY COMPRESSION OF THE FEMORAL ARTERY AT ITS UPPER THIRD.

By J. MONRO, M.D., Battalion Surgeon, Coldstream Guards.

This case (the author observes) is interesting from the fact which it proves, that a smaller amount of pressure than was formerly thought necessary will suffice for the cure of the disease. This being established, the chief difficulty in the steady application of pressure, the pain caused by it, is much lessened, the effects resulting from the undeveloped state of the anastomosing vessels are avoided, and a safer plan of treatment pursued, more especially when the tendency to arterial disease elsewhere in these cases is considered:—Drummer W. K——, aged 23, of a spare and delicate habit of body, walked to the hospital on the 19th of April, 1852. He complained of severe pain in the calf of the left leg, which was swollen, and the veins were dilated. Five days before, while playing at cricket, he was suddenly seized with pain, which obliged him to desist. He imagined he had met with a sprain. Although still suffering, he continued his duty; but to-day, being unable to go on any longer, he had come to the hospital. A large tumour, pulsating synchronously with the heart, was found to occupy the popliteal space. It was partially emptied by pressure, and returned to its former dimensions when that was removed. It expanded in every direction, and the bellows sound was heard. No other disease of the femoral or other artery was detected. The chest was free from disease, and the heart's action regular. He had suffered from time to time from slight catarrh and febrile attacks. He had been treated five times for venereal sores, but on one occasion only had taken mercury, and then but for ten or twelve days. After a little preparatory treatment, Mr. Phillips's instrument was applied, at first over the brim of the pelvis. The pressure could be borne only an hour and a half; it caused severe pain and feverishness. Believing that this arose in great measure from nervousness, the author employed manual pressure a little below the origin

of the profunda. This was effected by the aid of several intelligent convalescents. The artery was compressed only to such a degree as to allow a feeble pulsation in the sac. For the first three days this plan was followed for eight hours only during the day. The patient did not complain at all. There was no feverishness, nor increased œdema of the leg. The clamp tourniquet was now employed, but was removed each night; finding that it was well borne, it was kept on at night also from the 26th. On the 3rd of May the sac had become harder and smaller, the articular arteries more developed, and the œdema of the calf less. On the 6th the sac ceased to pulsate, and the tourniquet was removed. From this date the absorption of the contents of the sac went on rapidly, and he began to regain the use of his limb. In a short time the measurement round the limb diminished from sixteen inches and a quarter to fourteen inches and one-third; the femoral artery was pervious. On the 2nd of July he was dismissed to his duty, which he continued to do well till the beginning of November. Before that time his general health seemed worse. On the 19th November he was again admitted, and an aneurism of the aorta was found near the celiac axis. He complained of great pain in the loins and abdomen, coldness and numbness of the legs, faintness and nausea. On the 9th December he seemed to be fast sinking, and died on the following day.

On post-mortem examination, the heart was found of usual size—somewhat flabby on the right side, but the texture sound; valves healthy: no disease of lining membrane; the aorta sound to the situation of the celiac axis, between which and the superior mesenteric a rupture of its coats was found, and openings communicating with a large sac, of recent formation and filled with coagula. It had burst in two places, and several pounds of blood were found in the cavity of the abdomen. The aneurismal limb was injected: the femoral and popliteal arteries were of natural size and pervious, until opposite the centre of the popliteal space; femoral vein pervious and healthy; the profunda and its branches enlarged; slight thickening all that remained of the sac; popliteal artery obliterated down to its division into the tibial arteries; popliteal vein also obliterated; the anterior tibial artery enlarged; the posterior of usual size; the peronæal larger than usual; muscular branches large; the ramus anastomoticus magnus three times its usual size, its branches anastomosing with the inferior articular recurrent tibial, and with each other. Two superior articular and an azygos, given off by a common trunk, just previous to the remains of the sac, anastomosed freely with the recurrent tibial and peronæal.

The recurrent tibial was as large as the radial, and anastomosed freely with the articulars and plexus in the peronæal nerve; a tortuous plexus in the substance of the popliteal and peronæal nerves, united below with a recurrent branch from the anterior and posterior tibial behind the head of the fibula; another branch from the azygos communicated with the recurrent branches behind the head of the fibula. The communication between the external and internal articular was effected by branches three times their natural size; that between the anastomotica magna and inferior articular, between the recurrent tibial and superior articular, by large branches.

The PRESIDENT expressed a hope that some gentlemen present would offer their opinions on the subject of the interesting papers before them. After waiting a minute or two, and finding no one willing to commence the discussion, he said, that he quite agreed with Mr. Phillips in the opinion which he had expressed in his paper, that the treatment of aneurism by compression had not obtained that attention in England which its importance deserved, and which it had obtained in Ireland. The cause of this was probably the want of success which had followed this treatment in some cases in which it had been employed in this country; and the cause of this want of success he believed to have been a want of acquaintance with the true principles upon which this procedure produces the cure of the disease. It had been supposed that the pressure should be applied with sufficient force to flatten the sides of the

artery at a distance from the disease in actual contact, so as to cause the obliteration of its cavity by the adhesive process, and thus to place it and the disease in the same condition as when a ligature is applied to an artery in the Hunterian operation for the cure of aneurism. Such, however, was not the case; for in four instances in which the parts had been examined after death, and in which aneurisms in the lower extremity had been cured by pressure—three of which he had had the opportunity of inspecting, it was found that the artery at the part to which the pressure had been applied exhibited no change from its normal condition. In these instances the artery, throughout its whole course to the seat of the aneurism, retained its natural calibre; there were no vestiges of inflammation in any of its textures, nor in the surrounding parts; there was no adhesion of its sides, no plug, no contraction of its canal, and in short, no appearance of its having been subjected to any kind of treatment. In some of these specimens the aneurismal sac and the artery in the ham were filled with coagulum; in others, the sac only was filled with coagulum, and the circulation went on in the natural course of the artery. In Dr. Monro's case, which he had examined, the aneurism and the artery in the ham were obliterated; but above, where the pressure was applied, the artery was pervious and quite in its healthy condition. It was clear, therefore, from these facts, that the cure was not effected, at least in these instances, by producing adhesion between its sides and obliteration of the artery at the point where the pressure was applied. By what process, then, did compression cause the cure of the disease as effectually as the ligature of the vessel at a distance from the aneurism? From the recorded cases, especially from that communicated this evening by Dr. Monro, it was evident that moderate, but not "obstructive pressure," was that which was required. How did this act upon the artery? In addition to the three proper coats, which formerly were regarded as constituting an artery, modern histologists have demonstrated another texture, composing the inner portion of the middle or elastic coat, and, of course, situated between this elastic and the inner coats. In this texture resides the vital contractility of the vessel. Now it appears that when an artery is subjected to any irritation, this vital contractility is brought into action. When an artery is torn, or violently stretched and elongated, or exposed to a chemical irritant, it is by the agency of this vital contractility that its calibre is diminished; and in extreme cases this sometimes happens to such an extent that its area even becomes completely closed. Compression is one of the agents by which this power may be brought into action, and he believed that it was in this manner that long-continued moderate pressure produced such a diminution in the volume of the stream passing through the main artery to the disease, if not the entire suppression of the current, to cause those changes to take place in the aneurismal sac, by which the cure of aneurism is effected, when a ligature is applied at a distance from the tumour. In his opinion it was very important to keep this principle in view in adopting the means of treatment by compression; because by a moderate degree of long-continued pressure, we should produce all the good effects required, whilst great pressure would produce great suffering, which could be borne, if at all, with extreme difficulty, and often with most injurious effects upon the parts to which it is applied. Ample experience had now proved that long-continued moderate pressure was all that was required to bring about the cure of the disease, and not such a degree of violent pressure as would mechanically prevent the flow of blood through the vessel. The latter idea had, he believed, caused the failure of this practice in many instances in which it had been employed, whilst in others, by causing sloughing, and inflammation, and obstruction in the great venous trunks, and serious engorgement of the limb, its continuance was from necessity abandoned. Many years ago he had been engaged in some experiments on animals, in which attempts were made to procure the obliteration of arteries by powerful local pressure. In very few instances could this be accomplished; the sufferings which it produced were exces-

sive, and generally it caused inflammation of the veins, and most injurious effects upon the surrounding parts. The President concluded by expressing a hope that some of the gentlemen present would give their views on the subject of compression.

Mr. FERGUSON, after a pause, rose and said, that the circumstance of no one rising to address the meeting could not be from any want of interest in the subject, and he regretted that an older fellow than himself did not take the lead. He thought it a pity that so important a question should for the second time be passed over almost in silence in that Society, particularly after the interesting papers which had been read on the subject. The subject of compression in the treatment of aneurism was now attracting attention over the civilized world; and the surgeons in Dublin, Edinburgh, and elsewhere, where the plan had attracted much attention, naturally looked with some anxiety to what might fall from fellows of that Society upon the subject. He thought the surgeons present ought to give their opinion upon it. He (Mr. Fergusson) begged leave to say, that he accorded with the views of the Dublin surgeons, in advocating the employment of pressure in such a way, that, if it were general, would soon save any necessity for discussion upon it; for they not only brought forward arguments in its favour, but proofs, sufficient, in his opinion, to settle the matter. Thus forty or fifty cases had been recorded by the well-known names of Tufnell, Bellingham, &c., out of which only three or four had been unsuccessful. Now, in noticing the treatment of aneurism by ligature lately, he had occasion to state, that out of one hundred cases, sixteen had gone wrong. This fact alone was sufficient to show that compression should occupy the attention of every surgeon. In his opinion, the propriety of the operation, with respect to the lower extremity, was settled; but its applicability to the upper extremity involved a different question, for we could not apply compression there with the facility with which we could in the lower limbs. He thought Mr. Phillips and Dr. Monro entitled to something more than the usual form of thanks of the Society for their communications. It was worthy of note, that in Dr. Monro's case, pressure was kept up, under the surgeon's care, by that best of all compressors, the hand, for the space of three days; and this, he had no doubt, had had much influence on the favourable termination of the case. From his own (Mr. Fergusson's) experience of compression, and from the history of cases, he believed that both surgeons and patients were apt to despair too soon, and at a time when they should be full of hope and confidence. In one case, recorded by Mr. Phillips, this was well illustrated, Mr. Phillips having persevered with success after another surgeon had given up the case in despair. He (Mr. Fergusson) had seen a case which had been under treatment for nine weeks, without apparently making any progress whatever; but symptoms of cure soon after manifested themselves, and success was ultimately complete. The President had, in his remarks, raised one or two nice points for discussion. One was a suggestion thrown out with respect to pressure on the contractile coat of the artery. Now, without denying the influence claimed for it by so distinguished an authority as the President, he (Mr. Fergusson) should fancy that more depended really upon the pressure itself, than on the influence of the contractile coat. Now, pressure would obstruct the current of blood about one-third, more or less; yet the pulsation would continue; that amount of pressure quieted the circulation, and to this more than to anything else he attributed the cure. In calling in mind some points in Dr. Monro's case, he recollected that the calibre of the artery, from the upper part of the superficial femoral to the popliteal, was fully as great as in health. This was a fact in favour of the cure being effected by pressure only. Another proof was the circumstance that all the compression necessary was that which would impede, but not completely obstruct, the circulation. The same thing might take place in respect to a ligature, and it was only due to Mr. Wardrop to say that he had been the first to show that it was not necessary to entirely obstruct the circulation

through the aneurism, but only to diminish it to such an extent as would give rise to the deposition of fibrine.

Dr. J. A. WILSON said: "When in cases of popliteal aneurism, long-continued pressure of the femoral artery has been successfully employed, I should hesitate to explain the diminution of calibre in the compressed vessel by the hypothesis of an increased contractile energy in the artery at the part where compression has been made. I am inclined to consider such result as the effect of an impaired state of the general nutrition and special function of the arterial tube, under the disturbing influence of the long-continued pressure. Under this process of artificial structure, the close active normal relation of the artery with its contained blood is no longer maintained, and the consequences of such altered relation in the blood's current are of necessity first experienced in the aneurismal sac; subsequently, it may be in a prejudice and partial interruption of the circulation through the smaller arterial divisions of the limb. On this view of the effect of long-continued pressure of the healthy upper arterial structure in bringing about obliteration of the aneurismal sac, or prevention of its further development, the blood-current in contact with the compressed vessel is considered only a secondary agent in the change. From such violent interference with the complicated arterial functions, an effect necessarily follows on the force and volume of the blood's current through the compressed tube, with, as I believe, an incipient prejudice to the composition and delicate contractile properties of the blood itself; yet, such effect, if I am not in error, proceeds, in the first instance, from impaired nutrition and diminished contractile energy of the artery, which, however healthy and efficient in its structure and function, deteriorates, as an organ, from the first application of force by pressure to its self-adjusting tubercular cavity." He inquired the condition of the cellular tissue in Dr. Monro's cases.

Dr. MONRO replied, that there was no thickening of the cellular tissue external to the artery, the sheath being quite pervious.

Mr. CURLING had seen compression tried in two cases, and had come to the conclusion that more depended on the instruments employed than many supposed, and that very great care and attention to the case were necessary. In one case, which had been successful, in the London Hospital, the cure was mainly attributable to the great attention which Mr. Ward had paid to the case. Unless well managed, excoriation and sloughing readily followed the application of the pressure. In one of the cases he had seen the proceeding fail from this cause. Even with moderate and well-sustained pressure, success would not always follow, particularly in instances of very stout persons. He related two cases in which, from disease of arteries, a ligature could not be applied, and compression arrested hæmorrhage after amputation. He had seen one case in which pressure upon the brachial had been successfully employed.

No one else rising to address the Society, Mr. PHILLIPS said, that before the discussion closed, he wished to make two or three observations. The object he had in view in bringing the paper forward was, to determine, as far as possible, the benefits to be derived from compression; and whether we could do away with some of the inconveniences and difficulties which at present attended its employment. He could not help expressing his regret that more of the experienced surgeons present had not given their opinions upon the subject, so that it might be stamped with its true worth. He should, however, take it for granted, in the absence of any counter-statement, that compression should be continued to be employed as at present, until further experience enabled us to arrive at a better plan, if such there was. Now, it was clear that the operation succeeded in more cases than the ligature, and that a great number of successful cases had been published. It was open to the objection, however, of being more tedious, painful, and difficult to bear, than that by deligation. Now, he had wished to raise the question whether compression, applied with great care and improvement, might not be freed from

that objection. He (Mr. Phillips) had set it down that a moderate degree of pressure only was necessary, and that this might be sometimes intermitted. If pressure, with this qualification, were long enough continued, success would generally attend its application. A cure could not, of course, be expected in all cases. It had failed in one of the instances related in his paper, in which the artery had given way in front. The Dublin surgeons said the operation always failed in such cases, whether ligature or compression were the means employed. He (Mr. Phillips) did not know on what grounds they formed this opinion; but, in his own case, the joint had been injured by the arterial disease. But was it always so in these cases? These exceptional instances, however, did not militate against the value of the operation as a general remedy. He had therefore now come to the conclusion, that the smallest amount of pressure which would interrupt the flow of blood through the artery, kept up for a sufficient length of time, with occasional intermissions, would be well borne, and would cure aneurism.—*Lancet*.

### ACADEMY OF SCIENCES OF PARIS.

#### COAGULATION OF THE BLOOD IN ARTERIES FOR THE CURE OF ANEURISMS.

By Dr. PRAVAS of Lyons.

THE plan which Dr. Pravas proposes consists in coagulating the blood in the arterial vessels by the injection of a few drops of a concentrated solution of perchloride of iron. This is done with either a gold or platinum trocar, very finely pointed, introduced obliquely through the walls of the vessel with a rotatory sort of motion. The instrument being furnished with a syringe, and the piston worked by a screw, so that the injection would not be thrown in in jerks, and the quantity of liquid used measured accurately. Besides, the circulation in the vessel must be temporarily stopped, and some other precautions taken, which will be mentioned directly, after an account of the experiments performed.

1st. The carotid of a sheep having been exposed, the current of blood was interrupted by the finger and thumb, at two points distant, one inch and a half or two inches; about a spoonful of blood was thus enclosed. A puncture was made very obliquely in the walls of the vessel, and three or four drops of the perchloride of iron injected. For this purpose two turns of the screw were made, each turn ejecting about two drops of the fluid. Immediately after the injection of the salt, an increase in the density of the blood could be felt, and a clot forming rapidly. In four minutes the vessel could be left to itself, leaving off all compression; in fact, the clot did not change its position, and it could be felt in the same place for eight days subsequently.

2nd. A similar experiment performed on a horse gave the same result. The portion of the artery in which the circulation had been suspended, was about three inches long and could contain five teaspoonfuls of blood. Eight or ten drops of the solution were injected, Dr. Pravas having observed that it took nearly two drops of the solution to coagulate a teaspoonful of blood. In four minutes in the horse, as well as in the sheep, the clot was fully formed; it was firm and resisting, and was not displaced by the impulse of the blood for a quarter of an hour, at the end of which time that portion of the vessel subjected to the experiment was cut out and split; the inner surface was rough, and showed granulations and longitudinal striæ along the whole length occupied by the clot.

3rd. In another horse, a similar experiment was performed, with exactly similar immediate results, except that this animal was preserved for eight days, leaving the vessel exposed, so as to watch the progressive changes. It was observed that the induration of the carotid extended above and below the formative clot. At the end of eight days the horse was killed, and on examining the interior of the artery, three distinct clots were seen, which caused its obliteration for about eight inches and a half in extent. The middle clot corresponded to where the injection was

introduced, and had a darker-coloured and granular appearance, about an inch and a quarter long.

*Resumé*: After the injection of the perchloride of iron, four minutes and a half were sufficient to cause a clot in the carotids of these animals, so consistent and adherent as not to be displaced by the impulse of the column of blood from the heart.

The above experiments have been witnessed by M. Lallemand, and M. Le Coq, directeur de l'Ecole de Lyon. Dr. Pravas is still pursuing his researches, and has made these first results public, so as to draw the attention of experimentalists and practitioners to this plan of obliterating arteries. So far, his observations have been purely experimental, and instituted in such a way as to prove directly the mode of action of the coagulating agent he employs. As to its application for the cure of aneurism in the human subject, the proceeding ought to be thus modified: it is into the aneurismal sac that the solution ought to be injected, having previously arrested the circulation below the sac—that is, between it and the capillaries. The quantity injected should be in proportion to the size of the sac, and the compression below should last four or five minutes. This, in Dr. Pravas's opinion, will be sufficient to form an extensive clot, capable of plugging the artery and producing the same effect as ligature.—*Presse Méd. Belge*.

### ORIGINAL COMMUNICATIONS.

#### OBSERVATIONS ON THE TREATMENT OF SOME FORMS OF OBSTRUCTION OF THE BOWELS.

By THOMAS AICKIN, M.D.

THE fatal termination of the affection which has been termed "Ileus," or the "Iliac Passions," seems to be owing in many instances to the prostrating influence of the symptoms usually attendant on the local visceral lesion, independent of any progressive change of a necessarily fatal character occurring in the latter. Abercrombie's statement, that "ileus may be fatal without obstruction," and that "it does not appear to be necessarily connected with obstruction in any part of the canal," is calculated to excite some doubt as to the propriety of directing treatment almost exclusively to the removal of an obstruction, the nature, and possibly the existence of which continue to be matter of surmise and not of positive diagnosis.

I have had opportunity of observing the progress of some cases of obstinate constipation, in which the symptoms of ileus set in with great intensity. I have in some instances found it possible to subdue those symptoms many days before the removal of their assumed cause and the re-appearance of fæculent discharges; and I have remarked that the prolonged retention of the latter was not productive of dangerous consequences when the abdominal pain, vomiting, and general distress, were in the first instance controlled by appropriate treatment.

The first case which served to convince me of the injurious effects resulting from the repeated administration of purgatives, to the exclusion of other remedies, happened to be one of those in which purgatives seemed to be specially indicated. The patient, a young lady, had been subject to torpid bowels and pain, chiefly in the cæcal region; vomiting and severe abdominal pain supervened on protracted constipation. She was harassed for three days with these symptoms; the bowels remaining obstinately confined, notwithstanding the repeated exhibition of purgative medicine both by the mouth and per rectum; the stomach retained nothing, she had no sleep, and scarcely an interval of ease, up to the morning of the fourth day from the invasion of the acute symptoms, when I saw her for the first time. I found her much exhausted, the pulse very small, the extremities cold, and the nausea and straining to vomit most distressing; the bowels had not been moved for many days. On examination, a large and resistant mass was plainly perceptible in the cæcal region; it was about the size of a large orange; there was some surrounding tenderness: a blister had been applied over this region, and large quantities of purgative medicine admin-

istered before I saw her. Finding that the treatment previously adopted had been ineffectual, and that her strength was rapidly failing, I at once put her on calomel and opium—two grains of the former and one grain of the latter, in pill, were given, warmth applied to the extremities, hot stupes to the abdomen, and abstinence from all fluids, except cold water in small quantities, enjoined; the pill was retained, and the stomach became quiet. The calomel and opium were repeated every fourth hour. On the following morning—namely, the fifth day of her illness, I found that she had obtained upwards of six hours of sound and refreshing sleep, the vomiting had been arrested, but the abdominal tenderness had increased. General reaction was now fully established; the pulse, which on the preceding day was almost imperceptible, had become full and strong, and the countenance flushed. Twelve ounces of blood were taken from the arm, and in a few hours after leeches were placed over the cæcal region, and followed by a large poultice. The calomel and opium were persisted in. On the sixth and following days, she was almost free from general or local suffering; the gums became tender. Croton oil was now given in drop doses, which caused some return of the tormina; a blister was applied over the cæcal tumour; the blistered surface was dressed with mercurial ointment. On the tenth day, there were some small fragments of hardened fæces discharged after the administration of an enema; on the following days gentle frictions with mercurial ointment were repeatedly made over the mass in the cæcum, which ultimately broke up and was discharged piecemeal. Its fragments were of a dark colour, and strikingly resembled shoemakers' wax blended with some fibrous matter, both in their colour and amazing tenacity. This patient was sustained by the administration of enemata of beef-tea, thrown up by the tube. Three pints were thus given every day from the subsidence of the acute symptoms, until the stomach became able to tolerate food. Her recovery was perfect.

In another case of obstruction, accompanied in its early stage by the usual distressing symptoms, the sensation of pain and distress was chiefly referred to the umbilical region, several attempts had been made to open the bowels by the administration of oily purgatives, but without effect; the incessant retching proved so distressing that in the course of four or five hours from its commencement the patient became much exhausted. Calomel and opium were administered in pills, repeated every fourth hour. leeches were applied over the umbilical region, and iced water was allowed in small quantities. Under this treatment the vomiting became less troublesome, and the abdominal pain and tenderness were much diminished; large linseed-meal poultices were applied to the abdomen, and afforded much relief. Eight days elapsed from the commencement of the treatment of this case before fæcal evacuations were procured; no distressing symptoms were manifested after she was brought under the influence of opium. On the fourth day the gums became tender; the calomel and opium were now given at longer intervals. Attempts were again made to free the bowels by repeated doses of castor oil, and by large enemata, but up to the eighth day without effect; on and after which liquid fæces were discharged. Blistering the abdomen and mercurial dressing were also in this case attended with manifest advantage. Her recovery was unchecked by any untoward symptoms.

In another case of obstinate constipation, occurring in a lady who had been constantly obliged to resort to purgatives, the symptoms of obstruction set in with great violence. I found her on my first visit in a state of great exhaustion; she was straining at vomiting, and brought up frothy mucus in large quantity. She was so much sunk as to be unable to reply to the queries put to her; the pulse were scarcely perceptible, and the extremities cold. As soon as the cessation of the retching allowed a momentary pause, I gave her four drops of black drop in a teaspoonful of water, had warmth applied to the extremities, and enjoined as perfect repose as the nature of her suffering would admit of. After the lapse of an hour I found that the opiate had quieted the stomach, and that reaction was

beginning to set in. Hot turpentine stupes were applied to the abdomen, and ten grains of calomel and a drop of croton administered. Finding, after the lapse of some hours, that pain followed the purgative, and that the vomiting returned, I repeated the opiate, and directed the administration of a large enema containing turpentine and oil. The bowels continued obstinate, and the paroxysms of pain, which were evidently owing to the stimulus of the purgative, became very distressing. Black drop was again given; she passed a bad night, occasionally straining very much at vomiting, and brought up dark-brownish matter in small quantities. On the day following, finding that the bowels had resisted the purgative, and the abdomen continuing very much swollen and tender, I prescribed pills of calomel and opium; these were regularly persisted in for upwards of three days, until the gums became tender. After she had taken three or four pills, the symptoms were much improved; large enemata were occasionally exhibited, and her strength was supported by fluid nourishment given in small quantities. About the tenth day, the bowels were slightly moved, and on the two following days dark-coloured fetid discharges were freely passed. It may be remarked, concerning this case, that the first decided relief was obtained by opium, while the removal of the obstruction, whatever its immediate cause may have been, was obviously aided by the mercurial action, inasmuch as purgatives produced no effect previous to the manifestation of the latter; a few doses of castor oil were then sufficient to procure stools, after which nothing occurred to interfere with her recovery.

The causes of ileus are various, and their differential diagnosis is, in many cases, impossible. The affection may occur, as noticed by Abercrombie, in "the simple form, without any previous disease," or "with previous disease which deranges the muscular power without mechanical obstruction," or it may occur "with mechanical obstruction." Now, it is sufficiently obvious that when distressing or dangerous symptoms arise as consequences of an undiscovered or merely surmised lesion, our treatment should in the first instance be directed to their alleviation or removal. The possibility of effecting this, even when their exciting cause cannot be directly interfered with, is illustrated by every-day practice. Thus, the symptoms following obstruction of the bowels which are developed in virtue of an exalted reflex action, are controlled by sedatives which diminish the excitability of the nervous centres, and render them less capable of propagating morbid impressions originating in local disturbance of either function or structure. Hence the necessity of resorting to this class of remedies in order to check the diffusion of excited or perverted action, arising from any cause whatsoever. Hence the necessity of exhibiting opium in ileus occurring in any form, "with or without mechanical obstruction," when once the effects of an over-excited or perverted innervation are strongly developed. According to this view, it is applicable to every form of the affection accompanied by urgent symptoms, whether arising from intussusception or strangulation, from peritoneal adhesions or bands of lymph, internal or external irreducible hernia, impacted fæces, concretions, stricture, musculo-enteritis, and simple distension, with loss of power, &c. &c. Abercrombie states, that "a modification of the disease yields to a full opiate more readily than to any other mode of treatment." Mackintosh observes, that in ileus "opium seems to increase rather than diminish the laxative effects of medicines." The profound sagacity of Sydenham enabled him to discover a mode of treatment scarcely improved on by subsequent practice. For the treatment of the iliac passion, he directs that "blood be taken from the arm; after a few hours, twelve grains of scammony and a scruple of calomel are to be given; if rejected by vomiting, twenty-five drops of the liquid laudanum are given in half an ounce of strong cinnamon water. Should the vomiting cease, the purge is to be repeated, but should it return along with pain, and the cathartic be retained, the same dose of laudanum is to be again given, and to be repeated every fourth or sixth

hour until the motion of the intestine be perfectly quieted; after the action of the purge, the opiate is to be repeated twice, thrice, or oftener during the day, until the pain and vomiting have wholly ceased." Had Sydenham been aware of the remarkable effects of mercury pushed to salivation when it failed to purge in such cases, there would have been nothing to add to this method of treatment.

Amongst the many remedies employed in this affection, tobacco and belladonna enemata have been occasionally successful; the former is a remedy of much power, and its depressing effects are well known; the latter has been extolled by some modern practitioners, but is confessedly a dangerous remedy. Hanius, Wagner, and some others, have seen it followed by good results; the former has given the infusion of the root of belladonna, made by infusing a drachm in as much boiling water as would yield one ounce on straining; this, with an equal quantity of infusion of chamomile, is administered as an enema. (Cánstat, *Med. Clin.*) Messrs. Trousseau and Reveil direct dried belladonna leaves (gr. xv. to 3ss.) to be infused in eight ounces of boiling water for one hour, and strained; this quantity is to be administered as a glyster in cases of ileus from strangulated hernia. Amongst other remedies occasionally successful, are enemata of large quantities of warm or cold water, thrown up by O'Beirne's tube. Dr. R. H. Townsend of Philadelphia succeeded in overcoming an obstruction which threatened speedy death, by first throwing a quart of ice-cold water into the rectum, then suspending the patient by his feet to the ceiling of the chamber, and kneading the abdomen with considerable force; the signs of obstruction immediately ceased, and in fifteen minutes the injected water with feculent matter were evacuated. (Wood's *Practice of Physic.*)

I have succeeded in freeing the bowels in a case which had resisted powerful purgatives for a week by pumping up large quantities of strong soap-suds, by means of the tube and syringe. Rokitansky thinks that injections of air are applicable to cases of invagination. To be of any use, however, they must be employed before adhesions take place between the opposed surfaces of the invaginated bowel.

A host of remedies, familiar to most persons, have been from time to time resorted to for the relief of ileus; some of them are undoubtedly productive of dangerous effects. I have known shot to be swallowed, and strange to say the relief was immediate; but such remedies are rarely successful. In every case, it is indispensable that a minute examination of the abdomen should precede the use of remedies. There are instances recorded of death from strangulated hernia unnoticed during life; stricture of the rectum, or obstruction occurring in this bowel, should be sought for before resorting to active remedies. I have known the sudden occurrence of retroversio-uteri give rise to very severe symptoms of obstruction; in another case, attended with much pain, whenever the patient endeavoured to force a motion, a hair-pin was found to be firmly fixed by one of its arms, which had penetrated the recto-vaginal septum, whilst the other, remaining free, was pressed upon by the solid contents of the bowel, and inflicted so much pain, as to cause the patient to refrain altogether from straining at stool; the consequence of which was a large accumulation of hardened feces, which were dislodged by enemata after the foreign body had been removed by the aid of forceps.

**ARSENICAL CONFECTIONERY.**—At an inquest held last week at Ashford, upon two brothers killed by eating the painted ornaments of a twelfth cake, Professor Taylor, who analyzed the stomachs of the deceased children, said that he detected arsenic, which the system had completely absorbed. In his opinion, the yellow colour of the ornaments that contained the poison was produced by orpiment, or sulphuret of arsenic. The quantity that he discovered did not exceed a quarter of a grain. The green colour of these ornaments was imparted by the arsenite of copper, which poisoned in small doses. During the two last years he had met with ten fatal cases from children eating these ornaments.

## INFIRMARY REPORTS.

### REPORT OF THE COUNTY DOWN INFIRMARY, FOR THE YEAR ENDING JANAURY 5, 1853.

**INCOME**—Derived from parliamentary grant, £89 ls. 10d.; fines from petty sessions, maintenance of police and soldiers, miscellaneous sources, and interest from bank, £24 6s. 4d.; donations, £27 8s.; grand jury presentments, £450; life subscriptions, £71, and annual subscriptions, £43 10s.; total, £1098 16s. **EXPENDITURE**—£869 17s. 11d.

Patients under treatment January 6, 1852	...	51
Admitted since, up to January 5, 1853	...	686
Discharged during the year cured	...	499
Relieved	...	110
Incurable	...	39
Left of own accord	...	17
Discharged for misconduct	...	4
Sent to fever hospital	...	2
Committed to jail as dangerous lunatics	...	2
Died	...	21
Remaining under treatment January 6, 1853	...	42
Average number of days each under treatment	...	21½
Average number of beds occupied daily	...	40
Total number of beds for the reception of patients,	...	50

Cost of each patient while under treatment, £1 5s. 0½d.

The above includes the whole cost of medicine and appliances for 2043 extern patients. Many of the intern patients, it may be observed, came from the most distant parts of the county, and some even from Glasgow, Manchester, Liverpool, and Whitehaven, to seek relief at the infirmary of their native county.

Patients recommended for medicine and advice during the year	...	2043
Attendances, and prescriptions compounded, for the same	...	4023
Trusses supplied to the poor	...	52

The committee having presented the statistics of the infirmary, satisfied the governors of the continued usefulness of the institution; and they have only to add their thorough satisfaction of the manner in which affairs have been conducted by the various officers employed therein.

### ON THE EPIDEMIC MENTAL DISEASES OF CHILDREN.

Translated from the German by G. H. COOKE, Esq.

(From Dr. Winslow's *Journal of Psychological Medicine.*)

It is well known that children only learn to see and hear after a considerable time, though the organs of sight and hearing are from the first prepared to receive their appropriate impressions. There can be no question that the mental life of the child at this period is far inferior to the dreaming state of the adult: for though the suspended consciousness of the sleeper is scarcely stirred by the thread of ideas which flits across the mind, and is almost incapable of attention to them, yet these ideas may be perfectly clear in themselves, and even orderly; while in the child, when awake, they are only dim figures, without order and connexion. The faculty of speech is, we know, acquired by imitation of the sounds heard. The first modulated cries of the infant are not speech, but sounds without consciousness and significance; it learns to imitate the sounds presented to it, to show that it has received the impression they give. Gradually it associates ideas with the words, to which it then gives significance. It is not till a later period that there wakes up the higher faculty of recalling past ideas and the power of using words as the organ of thought. It is still long before the child can attain that mental independence which is regarded as the characteristic of man; the most can hardly be said to attain it at all, but continue through life dependent on circumstances. We constantly observe, in the amusements of children, that they are most absorbed in those which mimic the serious occupations of those around them—those of the school, the household, the family, the shop, and the church. Especially in times of popular excitement, we find the general topic repeated with perhaps greater earnestness, and the most engrossing plays of the children are the military attack or the parliamentary debate. In all this we see nothing but what is natural; we are aware that it needs guidance and restraint, but this is easily applied—the need of rest and food, and the quiet discipline of home, separates the most ardent playmates,

and subdues the most vivid enthusiasm. That the faculty should be morbid in its manifestations, it is necessary that the general feeling of society should be unduly, or, at least, unusually excited, and that either the domestic tie be feeble, or the position of children in society misunderstood. How widely spread, and how morbid an excitement may seize the youthful population under favouring influences is remarkably evinced in the children's crusade of the thirteenth century. At this period, the Holy Land had long been restored to the sway of the Saracens. Vexation for the loss, and an earnest desire for the recovery of this dearest possession of Christendom had spread with renewed earnestness among all the nations of the west. But the emissaries of Rome found no sympathy among the men, and not an arm was raised. They would not give their property and lives a useless sacrifice in the repeated effort at ■ achievement in which the skill and bravery of the past century had failed. But the children's minds were kindled with brilliant dreams of the Holy Land, and of miraculous victories over the infidels, and it was impossible that some outburst of feeling could be long delayed. The first impulse was given by Etienne, a shepherd boy of Cloies, near Vendôme, who must have possessed great address and talents. He gave himself out for an ambassador of CHRIST, who, he said, had appeared to him in ■ foreign garb, had received food at his hand, and given him a letter to the king. His sheep were said to have knelt down before him, to worship him, a miracle which perhaps was hardly needed to encircle him with the halo of sanctity. The shepherd-boys of the neighbourhood collected about him, and soon more than 30,000 persons streamed together to accept his revelations, and be transported by his preaching. He wrought miracles in St. Denys, the reports of which circulated with incredible rapidity through France. All rendered him homage, ■ the saint of the day and the messenger of God.

The king Philippe Auguste, alarmed at the excitement of so formidable ■ multitude, forbade the assemblies, with the sanction of the university of Paris. He might as well have forbidden an earthquake. Every day there started up new eight or ten-year old prophets, who preached, worked miracles, collected troops of young enthusiasts, and conducted them to the holy Etienne. To the inquiries put to these young pilgrims (for they were mostly clad in pilgrim's weeds) whither they were going, they replied, as with one voice: "To God." They went in orderly processions, headed with oriflammes; many carried wax candles, crosses, and censers, and they sang hymns without intermission, with most intense devotion, and to new melodies. In these hymns they often repeated the words "Lord, raise up Christendon, and give us again the true cross." It is to be regretted that the witnesses of a movement which thus engulfed the whole of the youthful population, have not recorded either these hymns or the music to which they were sung. Even the few words which have been preserved have not come down to us in the vernacular dialect. It cannot be doubted that thus many of the fairest flowers of national poetry have been lost, however overwrought and morbid the excitement which produced them. Many of the parents partook of the delusion, and furnished their children with arms and armour, or clad them in pilgrim's garb, and gave them a staff and wallet for their long journey. Some, who were kept back by force, wept day and night, and wasted away with fretting, or fell ill with nervous disorders, till they were allowed to go. Others made light of bolts and bars, and found means to elude the utmost vigilance of their attendants, that they might join the representatives of the holy Etienne, and at last behold that great crusade-preacher himself. All distinction of ranks was confounded: the children of counts and barons fled equally with those of burghesses and the lowest peasants. The richer parents, however, sent guides to accompany their children, many of whom it is probable were thus quietly rescued. Within a month from the commencement of the commotion, there was assembled at Vendôme an immense host of boys armed and unarmed, a few of them on horse, and among them not a few girls in male attire. The total number is reckoned at 30,000.

They all acknowledged the beloved Etienne as their captain and guide to the Holy Land, which they purposed to rescue from the Saracens. They put him in a splendid chariot; the noblest of the youths, in splendid equestrian accoutrements, formed his body guard, which indeed he needed, to restrain the ardour of his followers, who blessed themselves if they could but get a thread from his robe, when their devotion and enthusiasm had been inflamed by his preaching. On some of these occasions, a few were crushed to death in the violence of the press. In July, the extraordinary procession

set out for Marseilles. It was hot and dry; but none of the difficulties of the pilgrimage, neither the drought on the hot and arid plains of Provence, nor the scarcity to which the poor must have been exposed, after the first few days of the journey, could quench the ardour of their devotion and zeal. "To Jerusalem!" was their cry, when they were asked of the astonished beholders whither they were going; and none doubted Etienne's promise that the sea should divide before them, and they should go to the Holy Land dry shod. Disappointed of this expectation, on their arrival at Marseilles, they thankfully accepted the offer of two merchants of the city to convey them to Palestine without charge. They were still sufficiently numerous to fill seven large ships. Shortly after they set sail, two of the ships were wrecked in the bay, and not a soul saved. The remaining five were taken to Bugia and Alexandria, and all the children sold to the Saracens. It is satisfactory to know that the two merchants did not escape retributive justice. They were hanged in Sicily for another offence. At the same time a similar excitement sprang up in Germany, and repeated almost to the letter the incidents of the French boy crusade—the number of those drawn into it being probably somewhat larger. They were under two or more leaders, and went in two bodies toward the coast. It is probable that at least the half must have perished by the way, for the passes of the Alps were at that time very difficult, especially for such ill provided travellers; while the greater number of adults and women that attached themselves to these expeditions must have made the moral effects more disastrous. One of the detachments reached Genoa in August; the other entered Italy by way of Lombardy. Their fate was various. A large number met the same fate as the children of Etienne's army, being kidnapped in the Italian sea-port towns, and sold into slavery; some entered into service in Italy; some fell victims to seduction or violence, and abandoned themselves to infamy; some of noble birth established themselves in patrician families in Genoa. A very few only returned home.

Hecker relates, on the testimony of a contemporary chronicler, a monk of Pirna, that twenty-five years later ■ similar movement seized the youthful population of Erfurt. Above a thousand of these assembled on a particular day, unknown to their parents, left the town together, and went dancing and leaping to Armstadt. They were fetched back the next day, but none of them could say who had enticed them, or wherefore they had gone. This appears to have been more connected with bodily indisposition than the boy crusades. Many of the children continued ill long afterwards with chorea and epilepsy. Hecker conjectures (I do not know on what ground) that the proximate cause of this event was the religious solemnities connected with the canonization of a landgrave of Thuringia. From its proximity in time to the former event, he very reasonably supposes an excitable state of the "child world" at this epoch. More than 200 years afterwards, in the year 1458, a time when the St. Vitus' dance was very prevalent, more than a 100 children of Hale, in Suabia, set out, against the will of their parents, on a pilgrimage to Mont St. Michel, in Normandy. As all attempts to restrain them were fruitless, or hazardous, the corporation provided them a guide, and an ass to carry their baggage. They made the journey, offered their devotions to the Archangel Michael, and returned.

All these mental epidemics (if so we may call them) had this in common, that they produced an impulse to bodily activity—an impulse which, especially in childhood, may be regarded as salutary and critical. I do not suppose (in defect of information on the subject) that any permanent effects were produced on those who survived the hardships of the journey. It is recorded that, on the contrary, those who were kept back suffered much with chorea and convulsions, as well as with the anguish of disappointment, and that some died in consequence. There is another class in which we suspect the consequences may have been more lasting; more, we mean, which were connected with hallucinations, and which consisted in supposed commerce with the invisible world. The belief of witchcraft prevailed throughout Europe from the time of the Reformation, or earlier, down to within a century of the present time. As I am now only concerned with so much of its history as relates to its influence on children, I have not here to decide how much was imposture or malignity, but set down all, with a merely fractional deduction, to the score of delusion.

It will be remembered that, in this unhappy superstition, the children were regarded ■ the chief victims, ■ delusion which, as we may anticipate, they almost universally confirmed. Nearly all the children were seized with the com-

plaint. If their mothers were burned ■ witches, they themselves conversed with the devil, whom they saw hovering before them. They cried after their mothers, and all received answers from them. In sleep they felt themselves carried away by women in the form of cats, and when carried before the courts, they mentioned the names of the women who had thus carried them. This evidence, in which multitudes of children were unanimous, sufficed for the condemnation of those women to the stake. The children were carried into the churches, and were studiously kept awake. When overpowered by sleep, their dreams were repeated and they described all the doing of the witches, the appearance of the devil, the food he set before them, the dances they had witnessed, the conversations and songs they had heard. When these witches were burnt, the evil was by no means stayed; the children soon found themselves similarly treated by other women. They all agreed in the affirmation that bolts and locks were of no avail to detain the witches from the observance of their Sabbath, and that they had themselves been cruelly scourged by witches, who were at the very time in prison. This was regarded by the judges as an additional motive to hasten the execution of the sentence, and even a girl of sixteen years was burnt on her confession of having carried three children to the witches' Sabbath. The convulsive disorders occasionally prevalent in schools and nurseries are too familiar to us, historically, to require that I should allude to the case treated by Boerhaave in the orphan asylum at Haarlem, or similar cases recorded in the treatises on hysterical affections. From extensive inquiries which I have made among many of the great educational institutions in Great Britain, I cannot find any modern instances of these affections. In some of the excitements of religious revivals at the close of the last century, the children took much part, and were evidently morbidly affected. I have not been able, unfortunately, to procure the exact information on this subject. It will be remembered, that a few years ago children were much pressed into the advocacy of the cause of total abstinence, much I believe to the moral injury of some, and with fatal results to others. Beyond this, I do not know any modern events at all resembling those narrated at the beginning of this paper.

I do not refer to the supposed or actual increase of insanity at this period and in this country, which I think is not fully proved; nor to those severe affections of other parts of the nervous system, the prevalence of which in this country has compelled our physiologists on the researches which have given fame to this half century; but to what may almost be called the epidemic constitution of the educated classes of this country, and which constitutes the substratum of those diseases, while it modifies the nature and in consequence the treatment of most others. I refer to the nervous asthenia so prevalent in both sexes, but chiefly in the female, during ■ few years, commencing from the establishment of puberty. In the majority of cases it passes away with the full development of the body, and may never during its continuance have amounted to disease—amounting only in its collective symptoms to what we habitually call delicacy of constitution, and which it is quite needless to describe. It is impossible to collect statistics of what does not constitute ■ actual disease. I am compelled to rely on the statements of intelligent women, who almost unanimously testify in reply to my frequent inquiries, that this delicacy which they see in their daughters and granddaughters was almost unknown in their earlier days. This is confirmed by the testimony of the medical profession, that disease in general is more nervous and more asthenic than it was comparatively a short period ago. Probably the increased curability of diseases by nervous influence alone tends to further confirmation of the opinion. It appears to me, that it is impossible to observe the symptoms of this condition, and the manner of its gradual abatement, without feeling that it is ■ result of exhaustion only to be relieved by a protracted, but not passive rest. It is, if I may use such ■ figure, ■ temporary old age, not very dissimilar to the climacteric disease of old age. The present topic is one that chiefly concerns those who in any way have the care of the young—the clergy, preceptors, and parents. I am fully aware of the difficulty of the task at once to educate the child up to the point that shall qualify it to meet the excitement of the world, and to take care that the exercise thus given to the mind shall not restrain or impair the development of the body; and I am far from thinking that the difficulty is not on the whole judiciously met. I fear, however, that there is ■ undue tendency to call the young to aid of our religious institutions. Far be it from me to discourage youthful decision and activity in religious matters, but

to urge the necessity of care, in this more than in any other subject, that the child be not urged to do that which is properly the work of the man. If he does it in his childhood, there is a risk that he will not do it in manhood. Having hinted at what in some, not, I think, very many cases, is an error in the education of youth, I will mention, in conclusion, what seems to me the great desideratum of English society in cities. I mean scope and encouragement to active relaxation. It is with very little hope that they can be supplied that I allude to their needfulness. I fear that modern civilization has not as yet either the means or the wish to allow its younger servants that bodily exercise which might mitigate the strain which it imposes on their minds. The proper mental and bodily relaxants are music and the dance. It is a subject of much congratulation that the former is now recognized as almost one of the necessities of life. It is to be hoped that a better understanding of the value of the latter may ere long correct that mistaken morality which has driven it to late hours and heated drawing-rooms. No amusement is either healthy or moral which cannot be taken within the domestic circle, and at the hour when it is needed.

## MEDICAL PRESS.

SALUS POPULI SUPREMA LEX.

DUBLIN: WEDNESDAY, FEBRUARY 9, 1853.

## MEDICAL REFORM.

It is more with ■ view to the discharge of ■ duty which is annually imposed upon us at this period of the year, than with a hope of achieving much by our advocacy, that we return to the subject of MEDICAL REFORM. So utterly fruitless has every attempt to improve Surgical Education, or to correct the abuses which prevail in its management proved, that any proposal made with that view is treated with derision, and every man who ventures to express an opinion favourable to such an object is considered ■ visionary or ■ deceiver. Is this not so? Have we not at the very moment we write, the unquestionable evidence of daily experience to produce in support of the assertion we make? No man can open his mouth, or handle his pen, in support of any suggestion for the correction of abuses in our educational institutions, or for the removal of defects in our professional organization, with the slightest hope of sympathy or encouragement. The struggling practitioner, or the despairing aspirant to practice, impatiently repudiates the assumption that he has any interest in such matters, or that he is under any obligation to entertain the subject at all; while the successful candidate for popular favour, or the fortunate object of patronage, exultingly disclaims participation in any proceedings which may interfere with the pursuit of his prosperous avocations. In making this observation, we do not, however, mean to say that we feel particularly inclined to blame those much who pursue such a course; it is the natural result to be expected under the circumstances, and we only allude to the fact in support of our position, that reformers have little to expect in the way of assistance in such quarters. At the same time we cannot help saying, that we have our doubts as to the sincerity of these professions of neutrality; for when the shoe pinches, or the building shakes, we find that very unequivocal proofs are given of ■ keen interest in passing events; so much so, indeed, that the past leads us to fear that it is from this direction the most formidable resistance to reform is in future to be experienced. Even now we can perceive that the advocates of present arrangements, and opponents of any change which may affect their positions, reckon on the support of the classes to which we allude; relying on the discontent of the one and the apprehensions of the other. It was the same before. When,

ten years ago, one of the first fruits of our editorial labours displayed itself in the shape of a very unequivocal movement in favour of Medical Reform, the earliest and bitterest opposition was offered by the immediate recipients of the rewards which vicious arrangements confer; but those more remotely interested in the maintenance of existing systems soon became alarmed and joined them, and the masses blindly followed. The result was a postponement of the question *sine die*, and a period of languor as regards it up to the present day. The effort, however, was not without its results. The Colleges of Surgeons of London and Dublin obtained new Charters to enable them to meet the requirements of the times; and a Secretary of State introduced a bill into parliament to give effect to their provisions. Unfortunately, however, a political turmoil, aided by professional dissensions in England, came, and whatever of improvement the fear of change had produced was arrested, and a relapse of the worst character followed. The heads of the profession, as they then called themselves, retired from the contest, content with their victory, and the masses followed them, leaving the field in possession of the original defenders of abuses and malpractices, who, emboldened by success, from that time set no bounds to their proceedings. Elated with victory, they set at defiance all authority. A periodical registration of pupils, with a view to a verification of certificates, was attempted, and failed; sessional examinations of the students were tried only to be abandoned, and even permission to study in libraries was restricted as to become of little general benefit. Powers to grant Diplomas in Midwifery, after proper education and efficient examination, also became nugatory, in consequence of speculations in private diplomas in this department; and Universities, scarcely entitled to grant qualifications to practise Medicine, assumed a right to issue Licences to practise Surgery. All this took place; but this was not all. Discipline thus relaxed at the fountain-head, and charters and statutes openly infringed or evaded by those bound to execute them, naturally led to their repudiation by those bound to obey them, until a state of affairs unparalleled at any previous period has arisen. Mock lecturing, inordinate multiplication of teachers, imperfect attendance of students, and a wholesale trade in certificates, has succeeded; while the grinding or cramming process has been substituted for every species of legitimate instruction. We might glance at other consequences of this "leave-and-licence" system, if proofs of their occurrence could be adduced; but we must rest satisfied with a hint regarding rumours of private bargains between schools and hospitals which require contradiction. We write without reserve, but, we believe, without exaggeration; because we know that formidable maladies demand powerful remedies, and that no ordinary or tame remonstrance against abuses will suffice for the attainment of Medical Reform. We disclaim personal allusions; for the evils of which we complain cannot be attributed to particular individuals; and we still more distinctly disclaim any intention to attach blame to the Councils of the Colleges of Surgeons, because we are aware that both those of Dublin and London are now engaged in the discussion of measures having the correction of abuses and the removal of defects in view. If we felt inclined to attribute the mischief to any, we might perhaps venture to attribute it to the profession at large, or at all events to those members of it who have a voice in the election of Collegiate Councillors. If they perform their duties with firmness and integrity, complaints of this kind might

be less common. But how is it at present? Strange to say, it is upon the votes of Collegiate Electors the advocates of the *status quo* rely to perpetuate the present arrangements. Be the question under discussion by the Councils what it may, no man is to dare to deal with it on its merits: it is not whether a proposal is for the good of the College or the Profession, but whether this or that Councillor will *vote* for or against it; and at the moment we write, an active canvass is carried on in accordance with this principle. It is true that the parties engaged in these discreditable proceedings are not only numerically but otherwise in little estimation, but it is well known that a dozen or twenty unscrupulous men, banded together to vote through thick and thin in any body, must exercise a sinister influence on its deliberations. This state of things it is the duty of those entrusted with the elective franchise to counteract. Unless they strengthen the hands of their executive by cordial support, good laws can neither be enacted nor executed. We have often said what we now repeat, it is the Practitioner that is most deeply interested in the training of the Student; for sooner or later the Student must become a Colleague, and sooner or later will he discover that, if badly trained, he will prove a dangerous one.

#### MEDICAL RELIEF FOR POOR-LAW GUARDIANS.

THE following is valuable evidence of what may take place under the operation of the Dispensary Act. It is, we admit, too gross an outrage to be often repeated with impunity; but it proves that the Dispensary Surgeons are liable to such and similar demands. Our belief is, that there is not a union in Ireland without a *Mister NAUGHTON*, and perhaps more than one, two or three of them; and what is worse, that such may be found very generally on the Dispensary Committees:—

Dr. Dillon said he took the opportunity, which the meeting of the board gave him, of drawing the attention of the guardians to the great necessity of a careful supervision of the parties applying for medical relief; members of the several medical relief committees of the union, they should carefully inspect every case in which relief had been granted, in order that none but the poor who were entitled to it should be relieved. He had in the Brideswell dispensary discovered a case in point, which he would now bring under their notice, and which would show the great necessity of attention upon the part of the committee to their duties which were prescribed by the Poor-law Commissioners. He held a ticket in his hand which had been sent to the medical officer of the Brideswell district for medicine by a person named Peter Naughten, who was himself nothing less than a member of the committee, and, as he understood, a member of that board of guardians. This ticket was filled up by Mr. Naughten, signed by him, and at the bottom of it is written this addenda:—"Please send me a doze of castor Ile I thint. Sauttee wont anser me." This, it would be admitted, was an abuse of the charity, and he felt it his duty to call the attention of the board to it as well as to bring it under the notice of the commissioners.

Mr. Boyde wished to learn if there had been any meeting of the committee since that ticket had been issued?

Dr. O'Connell said, not since the ticket had been sent by Mr. Naughten, who was the guardian of the Dysart electoral division, and he (Dr. O'C.) felt it his duty to send the medicine.—*Westmeath Independent.*

Now, what we want to know is this: Has this man committed an offence for which the poor-law acts provide a punishment; and if so, will the Commissioners exercise the powers given them by these acts, or rather enjoined by them? The case affords an excellent opportunity for the vindication of the law, and for teaching a lesson to other Guardians similarly inclined, as well as to a host of persons who do the same thing in another way.

## CODE OF ETHICS OF THE AMERICAN PHARMACEUTICAL ASSOCIATION.

THE American Pharmaceutical Association, composed of Pharmacutists and Druggists throughout the United States, feeling a strong interest in the success and advancement of their profession in its practical and scientific relations, and also impressed with the belief that no amount of knowledge and skill will protect themselves and the public from the ill effects of an undue competition, and the temptations to gain at the expense of quality, unless they are upheld by high moral obligations in the path of duty, have subscribed the following "Code of Ethics" for the government of their professional conduct:—

1. As the practice of pharmacy can only become uniform by an open and candid intercourse being kept up between apothecaries and druggists among themselves and each other, by the adoption of the National Pharmacopœia as a guide in the preparation of official medicines, by the discontinuance of secret formulæ, and the practices arising from a quackish spirit, and by an encouragement of that *esprit de corps* which will prevent a resort to those disreputable practices arising out of an injurious and wicked competition; therefore, the members of this association agree to uphold the use of the Pharmacopœia in their practice, to cultivate brotherly feeling among the members, and to discountenance quackery and dishonourable competition in their business.

2. As labour should have its just reward, and as the skill, knowledge, and responsibility required in the practice of pharmacy are great, the remuneration of the pharmacist's services should be proportioned to these rather than to the market value of the preparations vended. The rate of charges will necessarily vary with geographical position, municipal location, and other circumstances of a permanent character; but a resort to intentional and unnecessary reduction in the rate of charges among apothecaries, with a view to gaining at the expense of their brethren, is strongly discountenanced by this association as productive of evil results.

3. The first duty of the apothecary, after duly preparing himself for his profession, being to prepare good drugs and preparations (for without these his skill and knowledge are of small avail), he frequently has to rely on the good faith of the druggist for their selection. Those druggists whose knowledge, skill, and integrity enable them to conduct their business faithfully, should be encouraged rather than those who base their claims of patronage on the cheapness of their articles solely. When accidentally or otherwise, a deteriorated or adulterated drug or medicine is sent to the apothecary, he should invariably return it to the druggist, with a statement of its defects. What is too frequently considered as a mere error of trade on the part of the druggist, becomes a highly culpable act when countenanced by the apothecary; hence, when repetitions of such frauds occur, they should be exposed for the benefit of the profession. A careful but firm pursuit of this course would render well-disposed druggists more careful, and deter the fraudulently inclined from a resort to their disreputable practices.

4. As the practice of pharmacy is quite distinct from the practice of medicine, and has been found to flourish in proportion as its practitioners have confined their attention to its requirements; and as the conducting of the business of both professions by the same individual involves pecuniary temptations which are often not compatible with a conscientious discharge of duty, we consider that the members of this association should discountenance all such professional amalgamation; and in conducting business at the counter, should avoid prescribing for diseases when practicable, referring applicants for medical advice to the physician. We hold it as unprofessional and highly reprehensible for apothecaries to allow any percentage or commission to physicians on their prescriptions, as unjust to the public and hurtful to the independence and self-respect of both the parties concerned. We also consider that the practice of some physicians (in places where good apothecaries are numerous) of obtaining medicines at low prices from the latter, and selling them to their patients, is not only unjust and unprofessional, but deserving the censure of all high-minded medical men.

5. The important influence exerted on the practice of pharmacy by the large proportion of physicians who have resigned its duties and emoluments to the apothecary, are reasons why he should seek their favourable opinion and cultivate their friendship by earnest endeavours to furnish their

patients with pure and well prepared medicines. As physicians are liable to commit errors in writing their prescriptions, involving serious consequences to health and reputation if permitted to leave the shop, the apothecary should always when he deems an error has been made, consult the physician before proceeding; yet in the delay which must necessarily occur, it is his duty when possible to accomplish the interview without compromising the reputation of the physician. On the other hand, when apothecaries commit errors involving ill consequences, the physician, knowing the constant liability to error, should feel bound to screen them from undue censure, unless the result of a culpable negligence.

6. As we owe a debt of gratitude to our predecessors for the researches and observations which have so far advanced our scientific art, we hold that every apothecary and druggist is bound to contribute his mite towards the same fund, by noting the new ideas and phenomena which may occur in the course of his business, and publishing them, when of sufficient consequence, for the benefit of the profession.

This is excellent advice, especially that in the last paragraph. We wish sincerely that people at this side of the Atlantic would take a leaf out of our brother Jonathan's book, for assuredly he is a wise man in his generation, notwithstanding his practical adoption of the obsolete adage, that "honesty is the best policy." After all, there is a great saving of time and money in going by the straight road, however agreeable it may be to go by the crooked one. But what will our friends, the "General Practitioners," say to the "pecuniary temptations involved in the combined practice of medicine and pharmacy?" Is it not worthy of observation that such keen people as our American brethren denounce such combinations and consider them suicidal.

## CORRESPONDENCE.

### CASE OF FLAP WOUND OF THE SCALP.

TO THE EDITOR OF THE MEDICAL PRESS.

DEAR SIR,—May I be permitted to make the following remarks in reply to some observations made on "A Case of Flap Wound of the Scalp, in which a considerable portion of the Skull was denuded of the Periosteum," the report of which was forwarded by me, and read at the Surgical Society on the 15th ult.

It has been asserted by Dr. Fleming, that "the complete union of an extensive flap wound of the scalp by the adhesive process, was an extremely rare occurrence in city hospital practice." Now I beg leave to say, that when I acted as resident pupil in charge of the Meath Hospital, I frequently saw scalp wounds treated on this principle; and the result was in every case satisfactory, and the union, as a general rule, invariable; and I recollect that when I was appointed house-surgeon to the City of Dublin Hospital in 1836, one of the very first cases which fell under my notice was that of a most extensive flap wound of the scalp, which occurred in the afternoon, and consequently fell under my immediate care. The patient was a servant who had been engaged in packing furniture, and was struck on the head by the sharp edge of some piece of furniture, which accidentally fell from the upper part of the van. A great part of one side of the scalp was completely stripped off, and hung down towards his shoulder. On ascertaining that the wound did not contain any dirt or extraneous matter, the flap was laid down, and retained in position by one or two sutures and some strips of adhesive plaster. The entire healed in a few days, strictly "by the first intention;" and I well recollect the astonishment of some of the junior pupils who had anticipated a much more tedious and troublesome recovery. The notes of this case are possibly to be found still in the hospital case-book. These were all cases occurring in metropolitan hospital practice.

Again, Dr. Fleming has assumed that the subject of the

case read before the Society, "was a hale country boy, enjoying a country residence," and lays some stress on the importance of this advantage. But in the notes forwarded, it was particularly specified that he was not healthy or robust; and it is further stated that he was brought to hospital presenting symptoms of concussion. It was these circumstances which gave the case peculiar interest, and invested it with more than ordinary importance. The fact was, he was a delicate boy, but indifferently developed for his age, residing in one of the liberties of the city, and but poorly fed; while the fact of his presenting symptoms of concussion bespoke some considerable direct violence, and justified the worst anticipations in such a constitution. On this account it was that inflammation or abscess of the brain were more particularly alluded to as possible consequences.

The well-known vascularity of the diploe of the skull enables us easily to account for the preservation of the external table, even stripped of its periosteum to a considerable extent. It was natural, however, to apprehend that matter might have formed between it and its proper membrane, which was completely isolated, and lay, as the flap was turned back, on some cellular tissue. Such, however, did not take place; and the true explanation, I believe, is that given by Dr. Benson, that "plastic lymph was thrown out between the bone and its detached membrane," which subsequently became organized, and reestablished the natural relations and dependencies of the parts. There is no other means, that I can see, of accounting for the result; for I can say, from a careful daily examination, that union took place here as soon as in any other part of the wound, and that during the healing process there was not more, nor even much, tenderness over this spot as over other parts of the wound. Finally, the only suppuration which took place was at a distance, in the back part of the wound, where the cellular tissue was more loose and abundant.—I am, dear sir, faithfully your obedient servant,

ZACH. JOHNSON.

Kilkenny, February 3, 1853.

#### TO THE EDITOR OF THE MEDICAL PRESS.

SIR,—As I am not a direct subscriber to your valuable PRESS, perhaps I am not at liberty to ask any question of you; still I am an indirect subscriber for some years. If you will please to answer me the following in your next PRESS:—Can any dispensary surgeon who is not able to reach on his duties employ an assistant, or should the guardians appoint a second medical man; or if such surgeon can employ an assistant, can he employ a man having only an apothecary's diploma?—Yours, &c.

February 7, 1853.

We should with pleasure answer this, were we not apprehensive that our reply might at the moment have a personal application. However anxious to afford information, we must keep clear of local differences. We may, however, be mistaken; and if so, we will reply presently, although the inquiry does not appear of so much importance, seeing that such arrangements are not provided for by written laws.

#### CURE OF ANEURISM BY COMPRESSION.

THE paper of Mr. Phillips, on the treatment of aneurism by compression, which was read at the last meeting of the Royal Medical and Chirurgical Society, is suggestive of some very serious reflections. It is well known to our readers that the subject has long occupied the attention of many of the most eminent surgeons in the kingdom. It is equally well known that, at present, opinions in the metropolis are much divided respecting it, although there are few surgeons in extensive practice here who have not to some extent tested its merits. With the view of bringing the matter fairly before the profession in this country, a paper was read last session at the Medico-Chirurgical Society by Dr. Bellingham.

Cases were detailed, and opinions asked for, and the author liating contrast to the discussions at the Academy of Medicine in Paris. The subject was left in the state in which the Society found it. Long ago, it would seem that the surgeons of Dublin had declared unequivocally in favour of compression; and certainly their good opinion had been formed upon what we believe to be sufficient grounds. Strongly impressed with the importance of the subject, and anxious that some decided opinion should be expressed upon it, Mr. Phillips himself took the trouble to come from Dublin to answer any questions, and to furnish any information which he was able to supply. What was the result? Certainly not a discussion worthy of the first medical society in the empire. Its poverty and meagreness, both in facts and arguments, afford a humiliating his paper to the Society. He was not contented with simply adducing many facts and arguments in favour of the improved system of treatment; he made a direct and urgent appeal to the members present, that they should state their experience and opinions upon it. The library was crowded; surgeons from every hospital in London, we believe, were present. Many of them had had experience of the treatment; but the really valuable and important paper failed to elicit a remark from many of the most distinguished fellows present; and this, too, in spite of an earnest and praiseworthy endeavour, upon the part of the President—himself no mean authority upon the subject—to elicit discussion. True it is, that Mr. Fergusson and Mr. Curling, after waiting in vain for older men to respond to the call, spoke well and ably to the point; but we must say that we join in the general dissatisfaction which was expressed, that only these two gentlemen could be prevailed upon to speak. Contrast this apathy upon a really important practical question, with the ardour and enthusiasm which animate the members of the Society when any personal question is at issue? Witness the gladiatorial displays on such subjects which took place during the last session or two in this Society. The contrast is indeed humiliating, and little encouraging to those members of the Society who bring papers before it of a really practical character. It is too late in the day now to assert that the Society is not for discussion. One of the ablest men who ever occupied the chair of the Society sufficiently set that question at rest. Sir Benjamin Brodie not only gave it as his opinion that discussion formed the more important object of the meetings, but he himself set an excellent example, by never failing to give the benefit of his great experience upon the subject of every surgical paper which came before the fellows. The Society cannot return to its former state. It can no more cease to be an oratorical Society, than it can return to its little meetings of six or eight. Why, then, should those whose names and reputation would confer a dignity and value upon the debates remain silent? It would be difficult to answer this question satisfactorily—*Lancet*.

Dublin: Fannin and Co., Grafton-street.

**UNIVERSITY OF ST. ANDREW'S.**

NOTICE is hereby given, that the next Examination for the Degree of DOCTOR OF MEDICINE will commence on Wednesday, the 4th of May. Fellows and Members of the Royal Colleges of Surgeons of England, Edinburgh, and Dublin, of the Faculty of Physicians and Surgeons of Glasgow, and Licentiates of the London Apothecaries' Company, are eligible for examination.

Every Candidate is required to communicate by letter with Dr. Day, the Professor of Medicine, fourteen days before the period of Examination, and to present himself to the Secretary for Registration on or before the 3rd of May.

By order of the Senatus Academicus,

JAMES McBEAN, A.M., Secretary.

St. Andrew's, February 2, 1853.

**TO THE MEDICAL PROFESSION AND THE PUBLIC.**

GEORGE OLDHAM AND CO.,

**APOTHECARIES AND CHEMISTS,**

in availing themselves of the present opportunity to return their grateful acknowledgments to their Friends for the support which they have hitherto received, and which they will regard as a fresh motive for exertion, beg leave to announce that they have taken the

ROYAL MEDICAL HALL, 64, DAME-STREET,

(Late Bewley, Owen, and Co.'s.)

which they will henceforward conduct in connexion with their MEDICAL HALL, 107, GRAFTON-STREET.

In notifying the above change in the management of the Royal Medical Hall, G. O. and Co. can assure the present Friends of that establishment, that the same scrupulous attention and care has been paid to the selection and preparation of their Medicines and other articles, which has gained them such extensive support in their Medical Hall, 107, Grafton-street; and they hope their arrangements to ensure accuracy, neatness, and despatch, combined with moderation of charges, will merit the approbation of those who may entrust them with their commands.

The Royal Shaving Cream, Essence of Ginger, Matico, Tooth Powder, Essence of Rhubarb, Ginger, and Chamomile; and other preparations heretofore made and sold at the Royal Medical Hall, can now be had at either Establishment.

107, GRAFTON-STREET,

AND

64, DAME-STREET, DUBLIN.

**A TREATISE ON CATARACT;**

Including the Structure of the Crystalline Lens, the Nature of its Opacities, and the Operation for its Removal by Absorption, with the Fine Needle through the Cornea.

By ARTHUR JACOB, M.D., F.R.C.S.,

Professor of Anatomy and Physiology in the Royal College of Surgeons, and one of the Surgeons of the City of Dublin Hospital.

Also, lately, by the same Author, 12mo, price 5s.,

**THE INFLAMMATIONS OF THE EYEBALL:**

Being a Treatise on all the Species and Varieties of Iritis.

Dublin: Fannin and Co., 41, Grafton-street, or the Office of the MEDICAL PRESS, 15, Molesworth-street. London: John Churchill, Princes-street, Soho.

**THE MIDLAND RETREAT,**

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY.)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System.

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

**TO SURGEONS, DISPENSING CHEMISTS, ETC.**

SULPHATE OF QUININE, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, capped, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

Wednesday, February 9, 1853.

Dr. HUTTON, President of the College, in the chair.

#### ON THE ADVANTAGES OF NOT OPENING THE SAC IN OPERATIONS FOR STRANGULATED HERNIA.

By WILLIAM HARGRAVE, M.B.,  
Vice-President of the Royal College of Surgeons, Professor of Surgery to the College, Surgeon to the City of Dublin Hospital.

(Case noted by Mr. W. W. Webb.)

MATTHEW D——, a grocer's porter, ætat. 23, was admitted into the City of Dublin Hospital on the 25th of October, 1852, labouring under oblique inguinal hernia of the left side, which had become strangulated.

*Previous history:* Health always good; has led a temperate life; his work has required constant exertion, with lifting of heavy weights. For about a year he has had a small rupture which he cannot trace to any particular exertion, and he was able to return the tumour at pleasure. For about a fortnight before admission he has suffered from pain in the groin, which suddenly increased considerably on Friday, the 22nd, while he was at work. He immediately went to bed, but got up on the following day, and returned to work, but was unable to do much. He vomited on Friday and Saturday. He lay in bed on Sunday, and on Monday he applied for relief at the Meath-street Dispensary, whence he was sent to hospital, where he arrived at two p.m.

On admission, he was in the following condition: Bowels confined, they have been since Thursday; countenance anxious and sunken; tongue foul; pulse very quick and small; very little hiccup; the belly is swollen, very tense, tender, and tympanitic; respiration hurried. On examining the left groin, a very tense but not very large tumour was seen, about the size of a walnut, and presenting the usual appearances of a strangulated oblique inguinal hernia. It was very tender, painful on pressure, and could not be returned in any degree. An ineffectual attempt was made to reduce it by means of the taxis. A consultation was held, and it was decided that an immediate operation was

necessary. Chloroform was administered, but the patient could not readily be brought under its influence; he, however, afterwards became fully affected. While under the action of the chloroform, a second attempt was made to reduce the hernia, but it was unsuccessful.

*Operation.*—Chloroform was again administered, but failed to produce in a well-marked manner its specific effects. During the performance of the operation, which was commenced by dividing the integuments from the vicinity of the internal ring to a little below the external one, which was found to form a firm stricture. On its being freed, an effort was made to return the hernia, which failing, I passed my finger beneath the tendon of the external oblique muscle, and divided it upwards to the internal ring, where I encountered another stricture, formed partly by the transversalis muscle and the ring. It was freely divided, and the attempt again made to reduce the hernia, which not succeeding, I opened the sac, from which flowed a large quantity of deeply tinged sanguineous serum. On introducing my finger into it, a firm stricture was found formed by the neck of the sac, which, on being divided, permitted the hernia, which was intestinal, to be easily returned. The intestine was much congested, flaccid, and of a dark chocolate colour.

The wound was dressed, and the patient conveyed to his bed. Deeming it unnecessary to occupy the time of the Society with the details of the progress of the case, which still possess some points of interest, I may state my sole object in bringing it forward, is to direct attention to the revival of Petit's operation by Mr. Luke of the North London Hospital—namely, *not to open the sac*, and which has proved so successful in his practice. The objections made to this operation in Petit's day (now near a century) were: 1st, the difficulty of the operation; 2nd, the fluids shut up in the sac may be returned into the abdomen and produce mischief; 3rd, intestine or omentum may be in a state of gangrene, or approaching to it, to which may be added, 4th, strictures of various kinds and other obstacles within the sac; 5th, adhesions.

These objections can be met as follows: Difficulty

of an operation should not deter the surgeon from it; the fluids effused are often returned by the taxis, and no sinister event follows it. If the contents of the sac are in a state of gangrene, oedema of the superimposed parts will indicate its existence, and the sac must be opened. Stricture within the sac and adhesions are more frequent in old than in recent hernia; still they may exist in recent cases of this disease, and require the sac to be opened. This operation was supported by Dr. Munro, Sir A. Cooper in some cases of small hernia advocated it; and practised it in large ones; the late Mr. Aston Key also was a supporter of it.

The advantages presented by this operation may be enumerated as follows:—It renders the operation less dangerous, by exciting a less degree of inflammation than when the sac is opened; there is no wound of the peritoneum, no exposure of the intestine to the air, which always acts as a stimulant to it, the operation is less protracted, the handling of the protruded parts prevented, which, however delicately managed, must add some additional mischief to the operation, and it can be considered as an adjunct to the taxis.

When we consider the mortality of the operations for hernia, as shown by the following statistics from Mr. Gay's work on "Femoral Hernia": Of 80 reported cases in "Guy's Hospital Reports" for October, 1838, 34 were unsuccessful; Royal Infirmary Edinburgh, from 1839-43, of 9 operations 4 died; Howship's "Appearance of Surgical Disease," 1840, 19 operations, 11 died; Anman in *Edinburgh Medical and Surgical Journal*, 1845, in 545 in the practice of the best European and continental surgeons, 260 died; Parisian "Report," of 1845, average ratio of mortality, 4 in 7; in Wartzburg, 3 in 7; in Mr. South's cases in St. Thomas's Hospital, in 16 cases, 6 unsuccessful; "Guy's Hospital Reports" from September, 1841, to December, 1842, 19 cases, 9 recoveries, 10 deaths; Mr. Luke's cases (82), sac opened in 25, deaths 8, recoveries 17—sac not opened in 57 cases, 7 deaths, 50 recoveries; St. George's Hospital, 1842-3, in 34 cases sac opened in all, deaths 9, recoveries 25. Mr. Luke, being unable to supply from his own case-book the result of cases operated on by opening the sac, has appealed to the authority of others, referring to the statistical details given by Mr. Textor, South, Malgaigne, and collected at the London Hospital; and from British journals generally, which gave a return of mortality of from one-third to more than one-half. (*Lancet*, 1848.)

This result is not very flattering to operative surgery. To what must this sad and discouraging detail be attributed? I shall leave this question at present for future examination, and would but express the hope that Irish surgeons, and those of Dublin in particular, will not follow the example given them by their brethren in England and Scotland some time since; who, either from apathy, indifference, or what is worse, prejudice, refused for a time to examine into and test the treatment of aneurism by compression, and ably revived in this city, I might say, brought back to the profession from things that were, and which at length surmounting every opposition, and forcing its way into adoption and success, and will yet become the rule for the cure of aneurism in certain situations, the ligature being the exception. Let our surgeons come forward, and by every legitimate way ascertain in what manner so great a mortality can be prevented; and record from their experience in what cases it will be prudent not to open the sac, and in what cases the contrary practice will be desirable. For the character of operative surgery—for the sake of our common humanity, we are called upon to re-examine into this most practical question, and if possible to place it upon a more successful foundation.

In my opinion, Mr. Luke deserves well of the profession in calling their attention to this subject, and from the strong feeling which holds possession of almost every surgeon's mind as to the necessity of opening the sac in every case, he has had to meet much prejudice, and perhaps charged with rashness and an uncalled-for innovation, in an operation which was considered finally and immutably

settled by the generality of surgeons, and incapable of further improvement.

The President observed, that Mr. Luke's statements formed a strong argument in favour of the operation; but at the same time, he thought that in the list of fatal cases which he had enumerated, it would have been of very great importance to have added an analysis, showing the cases in which the operation was performed at an early period after the symptoms of strangulation made their appearance. The great want of success in this operation was, he had no doubt, to be attributed to the handling of the tumour and the delay arising from the vain hope of returning the hernia. In his own experience, he had found that when he operated at an early period, a very large proportion of the cases terminated successfully; and he was therefore of opinion that in any list of fatal cases, a very careful analysis should be made, so as to trace the causes to which the fatality was due.

Mr. TURNELL inquired of Dr. Hargrave, how many of the list of eighty-two cases were in Mr. Luke's own practice?

Dr. HARGRAVE—They were all in his own practice. There was another question, connected with strangulated oblique hernia, which, as far as he knew, was not laid down in works on surgery. He remembered having under his care a strong, well-developed young man, who had a strangulated hernia of this description, and in this instance he was merely enabled to get his finger from the external to the internal ring, and then he succeeded in freeing the stricture and in returning the intestine. But from the delay he experienced in the operation, he came to the conclusion, that if he ever again met with a stricture at the internal ring or at the neck of the sac, he would never stop until he got to the internal ring by incising the tendon of the external oblique muscle, and since that time he had had two opportunities of acting on this determination, and the result had been so very satisfactory, that he had no hesitation in recommending other surgeons to follow his example. Another matter to which he wished to call attention was the manner in which surgeons were in the habit of seizing the tense membrane forming the sac of the hernia. In two cases which he had under his own observation, the membrane was so tense that no ordinary forceps could take hold of it; and in these instances he found that by using a common tenaculum he was enabled to grasp the membrane very readily and firmly, so as to come down on the diseased part in a short space of time.

The President said he recollected a case, where an operation was performed for strangulated hernia, and in which the greater part of the intestine was passed up through the inguinal canal. The sac or a small portion of it was left in the ring, and after the patient's death, the inguinal canal was found empty, but a portion of intestine was discovered at the inguinal ring where the obstruction existed.

Mr. BUTCHER remarked, that Mr. Luke had omitted to specify the relative proportions between the time of operating in those cases where the sac was opened and those where it was not. His statement with regard to his long list of cases went for nothing, unless he gave the length of time during which the strangulation had existed. When he was a student he saw a number of operations of this kind performed by Mr. Woodroffe, with unprecedented success, and in every one of these instances, the operation took place at an early period after the symptoms of strangulation set in; but if the patients had been allowed to remain some hours longer without surgical interference, the results, he believed, would have been very different. He was disposed to lay as much stress, as the President had done, on the advantages of operating as early as possible in these cases, and this was the point in which he conceived Mr. Luke's statements to be most defective. Some surgeons in Dublin had been very successful in their operations, but with others, almost every case had been fatal.

Dr. HARGRAVE thought the profession owed a debt of gratitude to Mr. Luke for the manner in which he had brought forward this important question under their notice. What they wanted was accurate statistical information on a subject, the statistics of which were not hitherto

as accurate as they ought to have been, coming from the medical and surgical professions. Mr. Luke's operations should only be met by a fair examination, and with regard to the comparative success of different surgeons, to which Mr. Butcher had alluded, he believed it to be due to luck or chance, more than to anything else.

Mr. BURCESS did not wish to detract from the merit to which Mr. Luke might be justly entitled, but he thought that all statements connected with a question of so much magnitude should be taken with great care and caution, more especially because Mr. Luke had omitted to mention "the time of strangulation." It was because he wished to have the subject sifted thoroughly, with the view of arriving at practical ends, that he had referred to it on that occasion.

Mr. TORNELL thought the wisest course would be (as Dr. Hargrave himself had stated) to endeavor to test the utility of the practice from that day forwards.

Dr. BENSON said it would be an advantage to compare this operation if found to be equally successful with the other, because it appeared to be of a rather less severe description. He thought a surgeon would hesitate less to perform the operation if aware that he might do so without opening the sac. In the case of the ordinary operation, there was a something which might make a man hesitate, and perhaps put it off for a lengthened period; but if the surgeon thought the former operation would be as successful as the latter, he might be tempted to press for its performance at an earlier period than he would if he knew that he should be obliged to open the sac, and expose the patient to what he knew to be a very formidable operation, involving, as it did, the cutting into a serous membrane.

Mr. BUTCHER—But it yet remains to be proved that it is a safe operation. For my part, I do not think that the difficulty of any operation should deter a surgeon from discharging what he feels to be his duty.

Dr. BENSON—No, certainly not; the difficulty of an operation might not deter a surgeon, but its danger might cause him to hesitate in the way I suggested.

Dr. HARGRAVE—There is one safety to the patient in not opening the sac. You perform the operation, and the sac not being opened, even the surgeon himself is prevented from handling the intestine. When a sac is opened in an operation, the intestine is almost invariably irritated by the manipulation of the bystanders; whereas, when the sac is not opened, the patient is saved from this hurtful manipulation, and even that I consider to be a great gain.

Mr. BUTCHER—I would say that a practitioner is highly reprehensible if he allows every person who may be standing by to put his finger into the wound, and handle the intestine.

#### ACADEMY OF MEDICINE OF PARIS.

M. J. PERSONNE read a paper on the "Presence of Phosphorus in Cod-liver Oil," of which the following is a summary:—1. That all the varieties of cod-liver oil do not contain phosphorus. 2. That this metalloïd is found in some as an alkaline earthy phosphate. 3. That the presence of this phosphate is due to a faulty method of preparing these oils, and shows its inferior quality.

#### BIOLOGICAL SOCIETY OF PARIS.

ON THE EFFECT OF SECTION OF THE CEPHALIC PORTION OF THE SYMPATHETIC NERVE.

By M. C. BERNARD.

Since the time of Pourfour Du Petit, who, in 1727, found that section of the cephalic portion of the sympathetic nerve caused contraction of the pupil of the corresponding eye, a great number of physiologists have repeated the experiment. In addition, it has been found that destruction of the superior and inferior cervical ganglions also, on the same side, causes a contraction of the pupil.

In 1845, M. Biffi, by galvanizing the upper end of the sympathetic nerve, when divided in the neck, saw the

pupil dilating. Lately, M.M. Budge and Valler have added a new and interesting fact. They have found that the part of the spinal cord which they call *sympathical*, can act on the pupil by the intervention of the sympathetic nerve.

In all these experiments one principal phenomenon has been kept in view—viz., the effect on the pupil, either its contraction or dilatation, which is explained as being an isolated paralysis, either of the radiating or the circular fibres of the iris, admitting, as Rust has pointed out, that the common motor oculi supplies the radiating, and the sympathetic the circular.

But the effects of section of the cephalic portion of the sympathetic, are not by any means restricted to the pupil. For some years I have been in the habit of showing in my lectures, that this section causes, besides contraction of the pupil, other varied effects; being, 1st, a contraction of the palpebral opening, which consequently causes deformation of the orbit, becoming elliptical and narrower; 2nd, a retraction of the eyeball towards the orbit, this retraction causing the third eyelid to become more prominent, it then covering the eye; 3rd, a contraction, more or less marked, of the nostrils and mouth on the side of section; 4th, an increased activity of the circulation in all the side of the face corresponding to the side of section, and consequently also an increased temperature in the parts. All these phenomena follow section of the cephalic portion of the sympathetic or destruction of the superior cervical ganglion, for they appear immediately after the performance of one or other of these operations. Galvanism produces directly the opposite effects. If the upper part of the divided sympathetic be galvanized, all the phenomena which ought to appear are checked, the pupil enlarges, also the palpebral outlet, the eye becomes prominent, and the circulation not so excited; so that the conjunctiva, nostrils, and ears, which previously were congested, become pale. On stopping the galvanic current, the effects again are manifest. This experiment can be repeated at pleasure, always with the same results, the only point to be borne in mind being, that the animals should be strong, such as horses, dogs, &c.

I have now pursued for a long time these researches on the sympathetic nerve; by and by I hope to publish the results. I only here wish to establish that it was wrong to limit the action of the great sympathetic exclusively to the pupil, its influence is much more extended. Besides, the theory by which it would be explained, that the effects produced on the pupil by paralysis of one of the two orders of muscular fibres on the iris, is only applicable to the changes in the pupil, but not to the other phenomena I have pointed out. In fact, the dilatation which is caused by galvanism of the upper end of the trunk of the nerve is involuntary, as the following experiment will illustrate. On the conjunctiva of a dog (whose sympathetic had been cut), a drop of ammonia was placed; the pain caused the animal to keep the eye constantly and firmly closed. Now, by applying galvanism to the upper end of the sympathetic, notwithstanding the pain felt, the dog could not keep the eye closed; the lids opened, and at the same time the congestion diminished, and almost disappeared.—*Gazette Medicale de Paris*.

#### EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Dr. GAIRDNER read a communication

ON THE CAUSES OF DILATATION OF THE HEART.

The object of the paper was to review the different circumstances under which dilatation, and the concomitant lesion of hypertrophy of the heart arise, and especially to determine, by the analysis of a considerable number of recorded observations, the relation of dilatation of the heart to diseases of the lung. The author observed, that obstruction of the circulation on the one hand, and debility or disorganization of the heart's fibre on the other, were the causes to which most cases of cardiac hypertrophy and dilatation were referred by pathological writers, the residual cases being usually considered as inexplicable on mechanical principles. Among the causes of obstruction in the course

of the circulation, leading to secondary disease of the heart, chronic pulmonary diseases, and especially emphysema, had been long recognized. Dr. Gairdner stated, that his own experience fully corroborated the assertions of authors as to the connexion of emphysema of the lungs with simple hypertrophy and dilatation of the heart; but he adduced numerous considerations tending to prove that obstruction in the pulmonic capillaries was not, as commonly supposed, the sole, or even the principal, cause of this connexion. From the examination of a variety of details, Dr. G. concluded, that emphysema of the lung, and simple dilatation or hypertrophy of the heart, very frequently coexisted, and stood in the mutual relation, not so much of cause and effect, as of joint results of a common cause; and that dilatation of the heart arose in connexion with pulmonary disease, under the same circumstances as the dilatation of the air-cells in emphysema—viz., when the capacity of the thorax was out of proportion with the volume of the lungs, these organs having suffered partial atrophy from some chronic disorganizing disease. Under these conditions (as Dr. G. had formerly attempted to demonstrate), emphysema arose by the effect of inspiration upon a lung not prepared to dilate equably, and therefore dilating irregularly, and, in some parts, excessively. Under precisely similar circumstances, the heart yielded to the dilating force of the external parietes, became habitually gorged and distended with blood, and finally became the subject of organic permanent dilatation, with or without corresponding hypertrophy. Dr. G. remarked that this theory of the connexion of cardiac with pulmonary disease was not only consistent with the facts already known, but would tend to explain numerous cases of hypertrophy of the heart, hitherto inexplicable, in which disorders of the lung of more recent origin have masked the original atrophic lesions. Such cases could only be properly understood by means of careful and correct clinical study.

Dr. BENNETT said that a case had recently occurred to him, bearing on the theory suggested by Dr. Gairdner. A young man had died in the infirmary after a protracted illness, and having had all the signs of a healing tubercular excavation in the left lung. On examination, this lung was reduced to little more than the size of a man's fist, and contained numerous small cavities, lined by perfectly firm and smooth membrane. The opposite lung was healthy, with the exception of a few traces of healed tubercle in the upper lobe. If atrophy of the lung were, as Dr. G. supposed, a cause of hypertrophy and dilatation of the heart, the latter affections ought, as it appeared to him (Dr. B.), to have been present to a marked extent in this case. The heart was, however, normal or nearly so, and he therefore appealed to Dr. Gairdner to reconcile the case with his theory, he (Dr. G.) having been present at the dissection.

Dr. WOOD thought it necessary to enter a caveat against the views of Dr. Gairdner, although from the mode in which he had treated the subject, and the number of details involved in the argument, he (Dr. W.) was not prepared to state all his specific objections. He thought that the older mechanical theories, and particularly the obstruction theory of cardiac disease, had been undervalued by Dr. Gairdner; and that the effect on the heart of the obstruction to the current of blood, could not be set aside, considering the illustration which it derived from valvular disease. He considered, too, that loss of tone from inflammation and other disease of the heart, was a very unquestionable cause of dilatation. The class of cases referred to by Dr. Bennett was a large and important one; and he thought that the theory promulgated by Dr. G. failed altogether as applied to phthisical cases.

Mr. GLOVER said a few words in objection to the inspiration theory of emphysema.

Dr. GAIRDNER said, in reference to Dr. Bennett's case, he thought the absence of cardiac disease admitted of a very clear explanation. The man was reduced to the last stage of emaciation and exhaustion long before death, and although the remains of extensive lung disease existed, there was practically no serious impediment to respiration, and no necessity for preternaturally strong inspirations. The

evidence of this was not only the absence of heart disease, but the absence of dyspnoea during life, and of emphysema of the remaining lung after death. The discharge from a large number of tubercular abscesses in the kidneys, had in fact operated as a drain upon the system, reducing the amount of blood to a conformity with the diminished breathing capacity. Accordingly, the body was emaciated and pallid, the chest tank and narrow on both sides, the whole of the organs smaller than usual, except perhaps the heart which was not at all remarkable. Hypertrophy and dilatation of the heart could not reasonably be looked for as a result of atrophied lung in a case like this; but he (Dr. G.) was perfectly willing to test the theory he had advanced by phthisical cases, and indeed had referred to them in his paper as illustrating it. He admitted that, in ordinary cases of phthisis there was no tendency to cardiac dilatation; but in ordinary phthisis, besides the existence of a constitutional condition unfavourable to over-distension of the heart, the local circumstances were altogether the opposite of those under which emphysema and dilatation of the heart occurred. Atrophy of the lung only occurred in very chronic and partially healing cases of tubercle; and accordingly wherever the cure of an extensive tubercular affection had advanced to a considerable extent without the counteracting circumstances in Dr. Bennett's case, Dr. G. had found that dilatation and hypertrophy of the heart almost invariably occurred to a greater or less extent. This proposition was entirely borne out by an analysis of his cases; and so far from tubercular cases being, as supposed by Dr. Wood, at variance with the law he had endeavoured to maintain, they had always been regarded by him (Dr. G.) as one of its principal illustrations. In regard to Dr. Wood's other objections to his paper, Dr. Gairdner would only say, that he had no thought of either overthrowing or of undervaluing the older theories for the sake of setting up his own. He had in fact strongly urged the evidence of both the theories favoured by Dr. Wood, but claimed a place in pathology for the new law, on the ground chiefly of facts hitherto unexplained, or which he at least thought he had shown by ample evidence not to be satisfactorily explained. With these remarks, he left the subject to the mature consideration and renewed observations of the members of the Society.—*Edin. Monthly J.*

## ON THE TREATMENT OF ANEURISM BY COMPRESSION.

By W. REEVES, Esq., M.R.C.S., L.A.C., Carlisle.

From what I have seen of the treatment of aneurism by compression, I cannot but feel assured that such treatment must become the rule of practice,—if it be not already the rule,—especially where the disease occurs in the extremities. The present case, which I send for your perusal, was cured—that is, the disease ceased to be active aneurism after the application of my compressor for the short period of four hours. The instrument I use admits of easy application. When once applied it does not shift its place, it is under the control of the patient himself, and affords means of alternate compression at the groin and lower down without change of instrument. The one instrument can be used for a double purpose; it possesses the quality of *multum in parvo*, a quality so much to be admired wherever to be met with.

W. C.—, a bookbinder by trade, and delicate appearance, enjoyed good health till within the last two years or less. He thinks his habits have not been very bad, "as he only got drunk occasionally like other working people." About May, 1851, while on tramp, his leg near the hough, used to feel painful and numb, and the foot swelled very much. Besides bathing the parts occasionally, when they troubled him more than usual, he paid no attention to the leg. When at rest the pain was not severe, but on any exertion the pain and swelling got worse. Within the last three months, the swelling near the hough obliged him to notice it, as it became considerable, and caused his knee to be very stiff and painful. He had a club-doctor to attend him, who thought it was an aneurism. The patient said

it throbbed and caused so much pain that he could not move about. I saw him on the 1st of April, 1852. Over the tumour the thigh measured sixteen inches and a half; round the sound leg only thirteen inches. The tumour was situated on the inner part of the thigh, just where the artery emerges from the canal of the triceps adductor femoris. It was a large pulsating tumour, considerably diffused, with a distinct bruit.

April 3rd. He is in a very debilitated state, obliged to keep his bed; pulsation of tumour weak, as his circulation is so low, the pulse almost like a thread, yet the stethoscope when placed on the tumour, is distinctly raised at each systole of the heart; tongue furred; no appetite; bowels sluggish. Ordered an aperient and mineral tonic. 5th. Much improved; appetite restored. Ordered nutritious diet. Aneurismal tumour as before. 6th. Compressor applied, and the compression to be alternated according to the feelings of the patient, and by the patient himself. 7th. Kept up an alternate compression for four hours yesterday, and then he removed the compressor so that he might sleep. 8th. Tumour as large as before, but firmer, and no pulsation can be discovered. 9th. No pulsation in the tumour; it is firmer, and more like a large ball; circumference over the tumour, sixteen inches; there is still some pain in the region of the tumour. 12th. No pain; no pulsation; circumference of leg over the tumour less; health improving. 20th. Circumference over the tumour fourteen inches and a half.

May 1st. Can walk without any assistance; tumour scarcely to be felt; circumference over the tumour, less than fourteen inches. He is still a delicate man, though much improved in health. He eats and drinks well, and, as far as the aneurism is concerned, is cured.

I think I read somewhere of a surgeon of celebrity who had condemned the treatment of aneurism by compression, as during the cure by this means a man might visit his friends in America and come back, and not find the patient any better. Such could not be said in the above case. I believe the cause of failure in treatment by compression rests with the instruments hitherto used, and not in the principle of treatment. Such a case as the above speaks for itself. With so delicate and broken-down a subject, an operation, such as deligation of the femoral, must have been hazardous, whereas the simple plan adopted could not be found fault with; its safety could not be disputed, and its success speaks for itself. — *Lancet*.

## ON THE EMPLOYMENT OF OPIUM IN MENTAL DISEASE, AND SOME ALLIED CONDITIONS.

By DR. FRIEDZ ENGELKEW of Oberneuland.

It will be interesting to our readers, to learn the views of our German brethren upon a practical point, which has particularly engaged attention in England. The author introduces his remarks by a few general observations upon the empirical misuse of medicines; and in the next place gives an historical sketch of his subject. The use of opium for mental maladies, among the ancients, Dr. Engelkeu observes, is very doubtful, since we have no written record thereof, and their theories of this class of diseases would be opposed thereby. The first distinct mention of its employment in mental diseases, he informs us, is to be found at the beginning of the eighteenth century, by Dr. Culleu. By Tralles and Wepfer it was given in increasing doses until sleep was produced. The views of Reil, the author remarks, coincide with those which guide the administration of opium in insanity by the best practitioners of the present day, as seen by the following quotation from that writer's treatise on fever. "In asthenic mania with erethism, not proceeding from any material (organic?) cause, opium administered in full doses from one to four grains, is of most essential service; it diminishes excitement, quiets the undue action of the brain, and causes sleep. Further, it is of great utility in cerebral disturbance from cold, accompanied with pain and spasms."

The writers, whose names we next meet with, are those of Fribourg, Pargeter, Chiarugi, and Friedrich; the

latter ranges the authorities into two classes, those opposed to and those in favour of the use of opium in insanity; among the former he enumerates Prichard, Haslam, Hasper, Goxi, Neville; in the latter, Chiarugi, Reil, Burrows, who have not, according to the author, sufficiently indicated the contraindications of its employment. Friedrich's indications for its use are excitement in a depressed state of the cerebral vitality, and the necessity for the production of a soothed state of mind. The influence of Brown's views Dr. Engelkeu remarks, was to hinder the use of opium in the cases now spoken of, and despite the commendations of Sydenham, its use was prohibited, and the treatment of mental disease was, by so much, prejudiced during part of the present century. Opium, Dr. Engelkeu observes, was formerly regarded as the common representative of all narcotics, but later researches have shown that its narcotic properties are unlike others of the class, while in value it surpasses all others. The mode of action of opium, advocated by the author, is that of those physiologists who consider it to have a twofold action, one local on the nerves of the stomach, the other remotely, on the nervous centres, by absorption into the blood.

In illustration of the effects of opium, the author quotes Reineke's description of the Persian and other oriental opium eaters, and observes thereon, that we may thence learn that opium may be administered in large doses, and for a longer continuance, than is generally admitted. In support of this opinion, Dr. Engelkeu cites several of his own cases, in which from one to three grains had been given with benefit once or twice a day, for periods of three or four years, and in one instance, with two short intervals, for a period of twenty years. We may observe, however, upon the supposed beneficial result in these instances, that time must be regarded as an important element in the cure. Dr. Engelkeu has often administered this remedy for three months, and longer, in different forms of mental disease, without having perceived any ill effects to have resulted; on the contrary, the appetite has improved, the entire frame has been benefited besides the marked and decisive amelioration of the mental malady. It has seldom been found requisite to give so large a dose as four grains. Medium doses have usually been combined with other means; regardless of the primary excitement, the use of the drug has been persevered in, limited to once or twice in the twenty-four hours.

The general influence of opium, the author divides into positive and negative, determined by the amount of the dose; thus, he describes small (e.g., half grain) doses as producing augmentation of the rapidity of the circulation, and of the quantity of the secretions; if the dose be raised to a grain, or a grain and a half, the actions of the brain are increased, with diminished susceptibility to external impressions. Thoughts are developed more rapidly and with greater clearness, the association of ideas is more varied, and imagination more active. A larger dose, e.g., from three to ten grains or more produces the well-known phenomena of stupor, &c. The author further observes, that taken altogether, the primary and secondary effects of opium are exerted upon the nervous system, producing, in general, a diminution of excitability, and an increase in the capability of action in the mental endowments.

Dr. Engelkeu enumerates the following as the chief points to be considered in the employment of opium:—The bodily constitution, the nature of the disease, the contraindications for its employment, the history of the disease.

The changes which time has introduced into our manners, customs, habits, &c. have had their influence in producing a greater development of certain feelings and passions, with their corresponding morbid conditions, and by their frequent repetition, induce a preponderance of the nervous constitution. Opium, the author states, is more suitable for those forms of hypochondriasis which most nearly approach to melancholia, as the former can, in many cases, be more closely traced to disorder of the visceral ganglia than of the brain itself, to which the morbid state applies more strictly in melancholia. In neither form, however, does the author look for great benefit from its

use. In general insanity, the utility of this medicine is observed when there is a degree of excitement; its continued use is then frequently of much service. In mania its employment is not required in the early stages, which are marked by more or less inflammatory or subinflammatory action. This state having been in some measure subdued, the author administers opium in doses of one or two grains, gradually increased to four or six grains, combined with calomel and digitalis; warm baths and corresponding regimen being enforced at the same time. In periperal mania the author recognizes as a disease of nervous excitement, with debility occurring in a peculiar inflammatory state, and a form of mania in which the best effects are obtained from opium. In idiocy and dementia, the author finds opium of no service.

Dr. Engelkew recognizes an asthenic and a sthenic form of delirium tremens, the former in his experience being more frequently met with in nine out of eleven cases. He administers opium in doses of from two to four grains with or without digitalis.

Chorea is a form of nervous disease, in which the author also states that he has witnessed the most decided benefit from opium. He gives it in increasing doses, of from one quarter of a grain to one grain, with children, of from 10 to 12, and continues its use for from two to eight weeks.

The contra-indications for the use of opium in mental disease mentioned by the author, are much the same as in other cases—e.g., 1. In insanity depending upon inflammation, with or without synochial fever. Besides inflammation of the brain, of which delirium is a symptom, there are many other distinct forms of disease, which in the acute stages, are attended by delirium, and for which an antiphlogistic, rather than a sedative, treatment is adapted. 2. In congestive conditions in the arterial (sanguine?) temperament, opium is injurious; whereas on the contrary, in the nervous and venous (lymphatic?) temperament, opium will, in the majority of cases, remove the congestion, especially when the exciting cause is to be sought in violent mental emotion.

With disease of the mind occurring in the asthenic state, the greatest caution is required in the use of opium.

With regard to the repetition of the doses of opium, Dr. Engelkew points out, that this must be determined by the constitution of the patient, and the effects of the previous administration.

The author also observes upon the error of regarding all narcotics as equally useful in mental diseases; and repeats his remark that they are not to be regarded as they were formerly, specifics for insanity.—*Psychological Jour.*

#### AMERICAN LARD.

By F. GRACE CALVERT, Esq., Of St. Louis.

DURING the numerous analyses I made some three years since of various articles of food employed in public establishments, I analysed several samples of American lard, and therefore may add to the fact already mentioned by Mr. George Whipple in your last number, that I found them to contain, in addition to starch, from 10 to 12 per cent. of water, and from 2 to 3 per cent. of alum, and about 1 per cent. of quicklime. A few months ago, I was able to ascertain that the operation is conducted in the following manner: The fatty matters, such as they arrive from America, are melted with a little water in false-bottomed copper pans, through which circulates a current of steam. The dirt and other heterogeneous matters fall to the bottom of the pans, and the clear grease is allowed to run into a wooden vessel when it is stirred in contact with cold water; it is then put under revolving wheels, with a thick paste made of potato starch, mixed with a little potash, alum, and quicklime, which appears to facilitate the taking up of the water and starch by the fatty matter. The cause of the American lard appearing so white, is, no doubt, the great division of the fatty matter through the interposition of the starch, water, and alumina. The quantity of alum should be such that a small excess should remain to prevent the starch from becoming mildewed, and I believe that the manufacturer also adds it for the purpose of communicating to the lard the property of facilitating the raising and increasing the whiteness of the confectioners' paste, in which it is employed largely.—*Phar. Jour.*

#### EFFECTS OF CLIMATE ON MAN'S GENERAL WELFARE.

By T. G. HARRIS, M.D.,  
Physician to the Suffolk General Hospital.

At the present hour, when millions of human beings are leaving their homes in Europe, or contemplating doing so, for countries which may or may not possess a climate similar to that which gave them birth, it cannot fail to be perceived that many interesting inquiries are thereby laid open to science, on which none but the physiologist can enter with advantage.

If the race of man, then, in all its varieties, affords a general expression of the existing climates of the world, in reference to the circumstances which contribute to healthy organization; if one climate maintains, while another modifies more or less the characteristics of human beings, as is undoubtedly the case, it cannot be out of season to make this investigation: With what result to his own physical conformation and moral character, and more especially to that of his descendants does man, born in a congenial climate, emigrate at random into different zones?

Having examined this subject in its many bearings, both by collating the written observations of travellers made cursorily without any immediate scientific object, and by questioning intelligent persons from our colonies, and other newly-formed states, I premise with confidence that it is one which is most important and curious. To take a common example: What a diversity of effects must obviously arise from one member of a family taking up his permanent abode in a portion of the American, and another in a part of the Australasian continent! Both regions afford climates which are called delightful and healthy; but their separate influence on the organization of the European is already perceptible. Indeed, it has been forcibly argued that man cannot travel out of his own zone without entailing extinction on his race. Be this as it may, an inquiry into the subject of isogenetic\* or congenial zones is of sufficient moment, under the existing conditions, and inevitable redistribution of nations, to give basis to a branch of science; nor will it be passed over without due consideration in this series of papers.

The classical ethnographer is of opinion that the human race is essentially migratory; that while it has enjoyed the character of being so from its origin, it is in obedience to the same instinct that it persists in pursuing its migrations into lands still unsubdued or unpeopled. But if it were true originally that the human race, being of common stock, fulfilled one of its great ends in spreading itself over continents, does it follow that the physical conformation of man is calculated to endure these changes of climate indefinitely? The race of man, physiologically considered, has its limits, like animal beings generally, many species of which have disappeared, some within our own time. Granting, then, that after one or more migrations, a particular race has become acclimated, as the Saxon, the Dane, and the Norman in this country; is it to be supposed that further migration, beyond our isogenetic zone, is in accordance with natural laws, especially at this not early period of human history, when disease to so large an extent is hereditary, and early death so general, as to mark an epoch in man's limited career? In answer to these inquiries, it may be assumed, that the type of man's physiological condition is expansive to a great degree, and that change of character in it is not incompatible with its integrity; but that beyond certain limits, such change as is effected by diversity of climate does hasten the fulfilment of the natural law of its extinction. With these preliminary remarks, the subjects intended for discussion may be approached in detail.

Climate, it will be found, is intimately associated with

\* I venture to introduce this term in order to mark the distinction between zones of equal geniality of climate, and those of like temperature, or isothermal zones, both of which differ from each other, and from geographical zones, as much as the magnetic differs from the common equator.

the history of countries. The Olympic games, the Greek drama, in common with the arts both of architecture and sculpture, are in some degree due to the influence of a cloudless sky. Rome owed her exterior splendours, Italy her palaces and unrivalled frescoes, to the same southern climate; while the vivacious Frank, rejoicing in an atmosphere scarcely less pure, delights in the imitation of Athenian taste, and Roman example, with their avenues, statues, and fountains. But the Englishman, enjoying equal, if not greater advantages, all of which are due to the climate of his native country, appeals, neither to sun nor sky; he is content to expatiate on the luxuriant verdure of his fields and hedgerows—on the perfection of his stock—on the breed of his cattle—on the manly character of his countrymen; and for the rest, he exercises his privilege of grumbling, however unjustly, at the ever-varying weather and leaden sky, through which these unexampled benefits are maintained.

What meaning, then, is to be attached to the expression, *good climate*, in the widest acceptation of the phrase? Though the sun of Greece may have inspired the dream of an *Acropolis*, and its realization, and somewhat later, but in the same spirit, may have marked out the boundaries of an eternal city on the plains of Italy,—of what avail is it, if human welfare prove not commensurate in duration with the glories of Nature? But so it is; the greatness of the South has been due to other causes than climate: it has arisen from a combination of human elements, the admixture of races having mainly contributed to the great result, the enduring monuments of which, climate alone was unable to sustain. Yet that some climates are better suited than others to the development of man—to the formation of his genius—to the growth of his physical powers—to the production of his supplies—is scarcely to be disputed. What country or region, then, beyond all others, has proved the most congenial to man; and in what does its geniality consist?

Excellence of climate is that quality which secures to any country its aptitude for the maintenance of intellect, strength, and health in the highest perfection, and for the rearing and growth of the supplies best adapted to the support of man. Some may, at first sight, pronounce this definition to be too strictly economical—too exclusive of the pleasures derivable from sunshine and a perpetual spring. But who can dispute the supreme blessing of health? And when this is once admitted, it cannot but be allowed that food, one of its chief sources, must take a prominent place also among human benefits. Nevertheless, it is highly probable that the custom of undervaluing—indeed abusing this climate, boasts a high antiquity. King Charles the First, with true discrimination, was among those who saw the subject in its true light; he observed, that in no other country was it possible to take exercise in the open air for so many days during the year as in England; and yet it has been reserved for the nineteenth century—that epoch of our scientific agriculture, of our success in sciences, in mechanical arts, in all that has its source in the intellect and energy of man,—to discover in how great a degree all this is due to climate.

Looking to exercise then as one grand source of health, let it be considered how many fine days, or portions of fine days, occur in all parts of England, however diversified, during the year. To the advantage our temperate climate thus affords, are attributable the vigour and symmetry of the men, and the corresponding beauty and freshness of our women. What other country boasts its pedestrians, who have accomplished the feat of walking over a thousand miles in a thousand hours? Where else are we to look for a race of prize-fighters like that which, through moral, not physical influences, is now disappearing? To descend in the scale, to what but to the climate of this country is the perfection of the horse attributable; and not of the horse only, but every other kind of animal?

As a grazing and agricultural country, England can scarcely be surpassed; but it is unnecessary to do more than allude to the produce of her soil, whether vegetable or animal. If the superior excellence of our stock is attri-

butable in the first instance to breed, no other influence than the climate could have perpetuated it; for the same stock, imported into less favourable regions, is known to deteriorate rapidly.

This utilitarian view may appear novel to those who have been in the habit of associating the spontaneous productions of the earth, and a perennial spring, with all that is desirable in climate—who, unaccustomed to the details of science, fall readily into the luxurious dream of the poet, in crediting the idea that the man of temperate zones can with impunity settle down within intertropical countries. But the true tests of a climate are seen in the quality of its productions; the constitution and temperament of the people living under it; the age to which they attain; and other circumstances of a like character, to which reference will be hereafter made.

This country owes its productiveness to the somewhat equable fall of rain which occurs throughout the seasons; to the moisture and warmth preserved to the land by a clouded atmosphere, which, by preventing a radiation of heat from the surface, tends materially to neutralise the effects which would else accrue from a high latitude. But these circumstances alone, while they may preserve it from becoming ice-bound during the winter, like other countries of the same, and of still more southern latitudes, are not sufficient in themselves to create the truly temperate climate we inhabit; other causes, of a most admirable and unique description, are to be looked to, not only in characterizing our zone, but in extending its geographical boundary over a great part of Europe.

A lake of warm water, having a maximum temperature of 86 deg. F. in the Strait of Florida, stretches across the Atlantic, from Cape Hatteras to the Azores; its greatest breadth being 120 miles, and its entire extent equal to that of the Mediterranean Sea. The origin of this tepid lake, whose waters are directed ultimately to our coast, and the western shores of Europe, is the Gulf of Mexico—an enormous cauldron, measuring one thousand miles in length, and seven hundred in breadth; having above it a tropical sun, which maintains a very high temperature in its waters. From this great sea, both the name and source of the Gulf Stream are derived. After passing between Cuba and Florida, and taking the direction of the American coast, it turns eastward, preserving a mean velocity, from the commencement of its course to the Azores, of thirty-eight miles a day; having a temperature of about 9 deg. Fahr. above that of the surrounding ocean in the Strait of Florida, which decreases so gradually in its passage to the east, as to have lost only 5 deg. Fahr. Opposite the south bank of Newfoundland, a distance of 1300 miles, it still retains a heat of 8 or 10 deg. above that of the adjacent seas, communicating its temperature to the superincumbent atmosphere. The warmth diffused over the Atlantic Ocean by this means would be sufficient—such is the calculation—to raise the entire column of air covering France and the British Isles, on a winter day, from freezing point to summer heat—a fact which accounts for the comparative absence of ice in the North seas, and affords the true explanation of the mildness of our climate, and that of adjacent countries.

But, while its influence, by means of the atmosphere, thus affects a large extent of climate, the Gulf Stream itself washes our western shores. The waters of the Atlantic are still warm as they wash the coasts of Connaught, while their effect is perceptible along the shores of Norway, and to the very borders of the Arctic Ocean.

And lastly, among the tributaries of our temperate climate, is the south-west current of air which is the prevalent wind of the northern hemisphere. Its gusts occupy the track of the Gulf Stream. They waft the warm moist air, arising from the contact and evaporation of its waters, over the coasts of Western Europe; they are felt in the same warm fitful gusts, from Cape Finisterre to the North Cape, as in the Atlantic, penetrating into the Baltic, and reaching to the Russian plains. It is the influence of this current which gives to the western coasts of these islands, from Cornwall to the Hebrides, almost the same isothermal line.—*Association Med. Jour.*

## MILITARY SURGICAL SKETCHES.

By W. E. HORNER, M.D.

Professor of Anatomy in the University of Pennsylvania,  
Senior Surgeon at the St. Joseph's Hospital, &c. &c.

THE concentration of numerous forces at Buffalo, New York, early in the year 1814, the arrival of many officers of high grade, the accumulation of large amounts of military stores, the daily drills and parades, lasting from eight to ten hours, the presence of Major General Brown, in command, with the recently appointed brigadiers, Generals Scott and Ripley, of the regular army, and the chivalrous General Peter B. Porter, of the New York Militia, all led to the conviction that a great enterprise was at hand, and the young medical aspirants of this division of the United States forces, and all of us who felt desirous of some degree of experience in surgical matters, for our better instruction, were likely to obtain it before long.

In the year 1813, I had seen but little service; my commission as hospital-surgeon's mate having come too late for any of the important field operations. The American force at New York consisted of about seventeen hundred men, and the British of about eighteen hundred. The former lost three hundred and twenty in killed and wounded, the latter about four hundred. Dr. James Mann, hospital-surgeon, being attached to the expedition, says that the American column halted at a distance of four hundred yards from the enemy's battery to reconnoitre, and that at this moment an explosion occurred, whereby sixty were killed and one hundred and eighty wounded, by the fall of stones which formed the magazine.

The attack on Fort George commenced on the 25th of May, and the assault on the 27th. The Americans had about four thousand troops, of which twenty-seven were killed and eighty-seven wounded. The British loss was estimated at one hundred and two killed and one hundred and seventy-five wounded. Dr. Mann, who was on the spot immediately after the action, says that he found four hundred men either killed or wounded, made up from both armies as they lay intermixed. Many capital operations were performed, both on the Americans and English.

On my arrival at Fort George, in August 1813, the army was tranquil, and there was no special duty for myself. At that time it had been determined that the forces should leave this position, and make a descent upon Montreal. The general hospital was then at Lewistown, under Dr. Mann. About this period more than one-third of the soldiers of the army were on the sick report; half of the medical staff attached to regiments were disabled. Of seven surgeons' mates belonging to the hospital, one died, three had leave of absence, and the other three were for a short period sick. At one time, with a sick list of some six or seven hundred men, only three surgeons were present for duty. The diseases were typhus and intermittent fevers, diarrhoea, and dysentery.

From the preceding battles, there remained many who, from the nature of their wounds, were incapable of further military duty. A detachment of seventy-three such soldiers was committed to my professional charge.

The encampments of the army at Buffalo were broken up July 1, 1814. Orders were issued for hospital preparations, a number of tents were left behind for future sick service, and for the sick of the regiments then on hand. The present Eagle Hotel and Railroad Depot of Buffalo, occupy the part of the city upon which the hospital was opened. On the night of the 2nd of July, the American army crossed the Niagara, and early the next morning Fort Erie was invested. In this affair, only two soldiers were wounded, one in the knee by a grapeshot, and another in the head by a buckshot. The first one must have had his knee in a flexed position at the time of injury, judging from the course of the ball. It entered on the end of the right tibia, opposite the head. It did not penetrate or injure the bone, but, dancing on, quelled upwards, came out in the inside of the anser internus, just above the knee. From the nature of the wound, and the pain the patient experienced, an unfavourable result was looked

for. The wound was dressed with a pledget of lint and a bandage, on the field, and the day afterwards brought to the general hospital. I removed the first dressing, washed the wound well with soap and water, and applied a pledget of lint spread with simple cerate, and confined it with a bandage loosely applied. The use of astringent spirits was forbidden; ordered thin soup and boiled rice, and to keep the limb undeviatingly in a straight position. On the fourth day after the injury, the pain of the limb increased, and a swelling of the joint was perceptible; the part was so extremely tender, that the patient could scarcely bear the falling of water on it from a sponge. A saturnine poultice was then applied, he was bled to the amount of a pint, and, in order to counteract the irritation of the wound which had kept him sleepless since its reception, an opiate was given. On the morning of the fifth day the pain had somewhat abated, the swelling was stationary, and a small quantity of pus was perceptible on the surface of the wound. The poultice was removed, and the opiate at night. This plan of treatment assuaged the violent pain, and the sore got into a healthy condition on the tenth day. The suppuration became very copious and healthy, and the tension of the knee removed; everything was then dispensed with, except the daily washing of the sore, and a dressing of cerate. The suppuration gradually diminished, the cicatrix contracted, the knee became flexible, and on the fortieth day after the reception of the injury, he returned to his military duties.

The other patient, who was wounded in the head, was a boy of 15, much esteemed in his company for his gallantry. He was brought to the hospital, the day after the injury, in a comatose state attended with delirium; however, when spoken to, his attention could be directed to the person who addressed him. The wound was extremely small, in consequence of being inflicted by a buckshot, was situated on the right temple, and had been closed up by the tumefaction of its edges, so that only a small bloody scab was visible; the temple was much swollen, and he complained of great pain in the right ear and back of the head. The wound being closed, prevented the probing of it. A poultice of bread and water (it being impossible to obtain milk) was applied by a bandage, but the patient from his restless and painful situation, did not allow this to remain more than an hour or two; it was frequently applied, and as often displaced, so that it was given up the next day, and the wound dressed with cerate. On the third day the appearance of the wound was not much altered, it had discharged a little blood and serum; the patient still restless, and moaning through excess of agony; pulse frequent and feeble; an anodyne at night, and a little soup was occasionally given. Fourth and fifth day, condition much the same as the preceding, only it was more difficult to obtain his attention, the delirium and comatose state having increased. Death put an end to his sufferings on the fifth day. On examining the head, it was found that the buckshot had passed through the temporal muscle and entered the cranium through the anterior angle of the right os parietal, just before the squamous suture, penetrated through the dura mater into the substance of the brain, and passed through the cortical part of it, not far from the right lateral ventricle, and lodged above the tentorium on the same side.

From the first day of July we had been busily employed in erecting hospital tents, procuring bunks and straw, and making every arrangement for the reception of a large number of wounded. On the 5th of July the battle of Chippewa was fought; many of the enemy's wounded fell into our hands, which added to our own, gave the surgeons of the hospital department as much business as they could well attend to. Many operations were performed on the field of battle, and all the wounded dressed there. The battle was fought on the banks of the Niagara river, and the wounded were brought up in boats to the general hospital at Buffalo. They were conveyed from the boats to the hospital—a distance of about four hundred yards—on blankets, the sides of which were nailed to poles; this formed an easy and convenient litter, by which four men

could safely convey one wounded without subjecting him to jolts, &c. Besides this advantage of the litter, when the wounded soldier was to be placed on it, it was spread smoothly on the ground and he slipped gently on; a litter thus constructed can be easily pulled from under the patient without pain, and is, in that respect, much better than the brancard or the handbarrow. The number placed immediately under my charge amounted to from sixty to seventy.

On the 25th of July, the battle of Bridgewater was fought, and was one of the most destructive field fights on record, for the numbers engaged. It crowded our hospitals so completely, that the attention of the surgeons was required unremittingly from early in the morning till night, besides the constant sick-calls at night. At one time I had the sole attendance and dressing of one hundred and seventy-three sick and wounded. My fingers became so sore from incessant dabbling in water and in pus, that I could seize nothing without pain, and was constantly liable to let articles fall, from the sudden twinges of agony in touching them. Our pressure of hospital business continued till the 4th of August, when an attack at Black Rock by a large force of the enemy, with the view of capturing the munitions at Buffalo and the troops in the hospital, occasioned a sudden and general dispersion. Our requisitions for hospital rations for some days before this affair, had been at eleven hundred.

The precise number of the wounded patients at this time, I have no memorandum of, but it included a very large amount; the wounded officers were generally quartered in the town. The danger of capture was so imminent, that while the action was in progress many of the hospital patients who were capable of shifting for themselves dispersed into the country, and others were removed to Williamsville, a small town of two or three hundred inhabitants, eleven miles in the interior. At this place a general hospital was opened, and I was placed in charge of the Buffalo one, as a receiving hospital for the army now hemmed in at Fort Erie. The hospital at Williamsville had for its chief medical officers Drs. Bull, Thomas, and Lovell. The latter was afterwards surgeon-general of the army, and had distinguished himself by his skill and zeal in the campaign of 1813, as well as that now going on. The hospital at Buffalo was directed to retain the most severe cases of wounds, and to send all others forward to the interior one, and to pursue this course for the remainder of the campaign. My care for the time was thus reduced to eighty or ninety, whose condition forbade removal. A physician in private practice in Buffalo, Dr. Coltrin, was allowed me as an assistant; he had been the partner in practice of Dr. Cyrenus Chapin, the oldest physician of the place. Dr. Chapin had been equally distinguished in his profession and in a military career. He was colonel of a regiment, and as such accomplished several remarkable feats of bravery, by his resistance to frontier attacks, his hostile incursions into Canada, and a singular recapture of himself on Lake Ontario in an open boat, by rising, with some other American prisoners, upon the guard, and bringing boat and all into the American territory.

On the 15th of August, a general assault was made on the American works; and while a column contended for a bastion of Fort Erie, a magazine near it exploded, and threw the enemy into the air. The wounded by this explosion were truly most pitiable spectacles. Some blackened over the whole face, and their heads swollen to two sizes; eyes burnt out; limbs mangled; clothes torn from scarified backs, &c. &c. There was scarcely a description of wound which was not exemplified amongst them. The military man sees in these events the steps of his glory; but the surgeon has only the impression of the woes of war. He only hears the groans of the wounded, and sees the horrid mutilation of their bodies, their want of comfortable accommodation and provisions, and the imperfect attendance from press of business. Since the 2nd of July, our hospital had been recruited by two pitched battles, one general assault upon our position at Fort Erie, by the defence of Black Rock, and by skirmishing, bombarding,

and cannonading, from day to day, with scarcely the interval of an hour.

From the preceding narrative, it may be inferred that every description of wound was to be met with—from musket ball, grapeshot, cannon ball, fragments of shell, and all missiles used in warfare. There were but few instances on either side of bayonet wounds, the troops seldom closing. One day, in making my hospital rounds, a patient just arrived presented an amputated forearm, and in doing so could scarcely restrain a laugh; the titter was constantly on his face. "What's the matter? this does not strike me as a subject for laughter." "Excuse me, doctor; I lost my arm in so funny a way that I laugh whenever I think of it. Our sergeant wanted shaving, and got me to attend to it; we went out in front of his tent, I lathered him, took him by the nose, and was about applying the razor, when a cannon ball came, and that was the last I saw of his head and my hand."

The crowd of wounded brought in by the field of Bridgewater, reduced, unavoidably, attentions to individuals; the utmost possible was done, but it did not come up to the point. Under these circumstances, many soldiers were treated in the outskirts of the hospital by their wives, or females having an attachment to them. With such assiduities, recoveries took place which would scarcely have followed in the then ordinary hospital practice. A boy shot in the forehead, with the ball penetrating to the back of the neck, along the base of the face, whom I had seen on his first arrival and dressed, and given up for a fatal case, pleasantly surprised me some weeks after in a state of convalescence; and a soldier badly shot through the lungs, was in the same way. So much for assiduous nursing, congenial food, cleanliness, and good poultices.—*Amer. Med. Examiner.*

#### DIVISION OF THE TENDO-ACHILLIS IN FRACTURE.

(Under the care of Mr. SHAW in Middlesex Hospital.)

THE division of the tendo-Achillis, as a means of facilitating the reduction of fracture of the leg, in cases where such reduction presents difficulties, seems now to be pretty generally used in our hospitals. This practice, which originated in Germany, and has been adopted in several countries besides England, has the great advantage of allowing of reduction without the powerful traction (and accompanying pain) which must sometimes be used in cases of complete riding or widely-displaced fragments, when the gastrocnemius muscle draws the lower fragment upwards with a great degree of force.

Mr. Shaw has now in Clayton ward a male patient, aged 40, who was admitted January 19, 1853, with a simple fracture across both malleoli, with complete twisting of the foot outwards and towards the front of the leg. Reduction was found extremely difficult, and Mr. Shaw thought it advisable to divide the tendo-Achillis, to render the parts more yielding and manageable. This measure had the desired effect, and the leg was easily reduced; the limb was then placed into the usual apparatus (side-splints and foot-piece), and the patient is now doing extremely well.

We noticed in the same ward a severe case of compound fracture of the leg, in which the same procedure was resorted to with great benefit. The man was admitted October 26, 1852, and is aged 61. He was run over by a cab, and suffered a compound fracture towards the lower third of the leg. The fragments were so widely separated, and the action of the gastrocnemii and solei muscles so powerful, that Mr. Shaw was obliged to divide the tendo-Achillis, besides removing a small portion of bone. Reduction became then comparatively easy. Suppuration has been profuse, and the diligent exhibition of stimulants became necessary; but by dint of care, cleanliness, &c., the patient has done well, and the wound was almost healed three months after admission.

Mr. Hilton had lately recourse, at Guy's Hospital, to the division of the tendo-Achillis in a case of compound fracture

of the leg of a very severe kind. Reduction was found extremely difficult before tenotomy was performed, the separation of the fragments was considerable and the traction of the muscles insupportable. After the division of the tendons, the limb was secured in a comfortable position, and by the use of opium and stimulants, the patient is likely to recover without the loss of his leg.

Mr. Hilton has had two other cases of the same description, in which tenotomy proved very beneficial. One was that of a woman aged 67 who was admitted with compound dislocation of the ankle joint. Mr. Hilton proposed amputation, but the patient would not consent; he was therefore obliged, in order to bring the patient into a tolerable position, to divide the tendo-Achillis, the peroneal tendons, and the tibial tendons. By the continued use of stimulants, &c., the patient recovered, and has just left the hospital, with an ankylosed and hardly useful joint.

The third case refers to a woman who suffered simple fracture of the lower third of the tibia and fibula. The foot became so elevated by the action of the peroneal muscles, and the lower fragment was so strongly pulled upwards, that Mr. Hilton divided the tendons of the peronei and the tendo-Achillis. Reduction was then effected with comparatively little trouble, and this patient has also done well.—*Lancet*.

#### FLUID EXTRACT OF RHUBARB AND SENNA.

By WILLIAM PROCTER, JUN.

NOTWITHSTANDING that two preparations of rhubarb and senna are already known, it is believed that the new one, now proposed, possesses sufficient claims to gain for it the favourable opinion of physicians and patients in many cases where a cathartic is needed, simply as such, or in connexion with other medicines. It is well known that senna has little, if any, tonic influence on the alimentary surfaces; that an over-dose has a depleting effect, often inconvenient, and that griping is a frequent attendant on its exhibition. On the other hand, it is equally understood, that rhubarb is remarkable for being a sort of therapeutical paradox, in so far as it possesses both a purgative and an astringent property, the latter coming into play after the former has manifested itself, and thus repairing, as it were, its effects. It is also well known, that this astringent or tonic action is so strongly marked, that it is necessary in most cases to combine it with some other cathartic to overcome or modify this peculiarity when a simple cathartic is needed. By the union of these two drugs in the concentrated form presented by a fluid extract, and in a due proportion, a resulting cathartic action is obtained which is safe, unattended by unpleasant symptoms, and not followed by constipation when the dose has been properly graduated. It has been ascertained that the associations of alkalies and alkaline salts with rhubarb and senna, has a tendency to prevent their unpleasant griping effects, and in the case of senna to increase its activity. The introduction of the bicarbonate of potassa is with this view, and the aromatics from their carminative properties also aid.

The following is the formula:—

Take of senna, in coarse powder	twelve ounces (troy)
Rhubarb, in coarse powder	four ounces
Bicarbonate of potassa	half an ounce
Sugar	eight ounces
Tincture of ginger	a fluid ounce
Oil of cloves	eight minims
Oil of aniseed	sixteen minims
Water and alcohol of each a sufficient quantity.	

Mix the senna and rhubarb (by grinding them together in a convenient way), pour upon them two pints of diluted alcohol (U. S. P.), allow them to macerate twenty-four hours, and introduce the mixture into a percolator furnished below with a stop-cock or cork to regulate the flow. A mixture of one part of alcohol and three of water should now be poured on above, so as to keep a constant but slow displacement of the absorbed menstruum, until one gallon of tincture has passed. Evaporate this in a water-bath to eleven fluid ounces, dissolve in it the sugar and bicarbonate, and after straining, add the tincture of ginger, holding the oils in solution and mix. When done the whole should measure a pint.

Remarks.—If the percolation has been properly conducted, the ingredients will have been sufficiently exhausted when six pints of fluid have passed. As by far the larger portion of

soluble matter passes in the first two pints, it is well to set these aside and evaporate them separately to six fluid ounces, subsequently adding to the other liquid when it has been reduced to five fluid ounces. As the cathartic principles of senna and rhubarb are very susceptible to injury from heat, especially in contact with the air, the propriety of using the best available means for conducting the evaporation need not be urged. When the evaporation is conducted in open vessels, some advantage is gained by adding the sugar to the tincture and continuing the process until it measures fifteen fluid ounces. The sugar protects the extractive matter from oxidation, and more completely suspends or dissolves the resinous part of the rhubarb contained in the tincture. The bicarbonate should not be added to the extract while it is above 40 deg. F. and should be reduced to powder previously.

It may be objected to this formula that we already have fluid extracts of rhubarb and of senna of the same ratio of strength, and that when physicians need such an association they can mix them. In answer it may be stated that the cases where a simple cathartic is needed, are so numerous that this preparation will be found useful to the physician, and a good medicine for travellers and others who resort to this kind of purgative habitually.—*Amer. Jour. of Pharmacy*.

#### LIQUID GLUE.

By M. S. DUMOULIN.

ALL chemists are aware, that when a solution of glue (gelatine) is heated and cooled several times in contact with the air, it loses the property of forming a jelly. M. Gmelin observed, that a solution of isinglass, enclosed in a sealed glass tube and kept in a state of ebullition on the water-bath for several days, presented the same phenomenon, that is to say, the glue remained fluid, and did not form a jelly. The change thus produced is one of the problems most difficult of solution in organic chemistry. It may be supposed, however, that in the alteration which the glue undergoes, the oxygen of the air or of the water plays a principal part; what leads me to think this is the effect produced upon glue by a small quantity of nitric acid. It is well known, that by treating gelatine with an excess of this acid, it is converted by heat into malic and oxalic acids, fatty matter, tannin, &c. But it is not thus when this glue is treated with its weight of water and with a small quantity of nitric acid; by this means glue is obtained which preserves nearly all its primitive qualities, but which has no longer the power of forming a jelly. Upon this process, which I communicated, is founded the Parisian manufacture of the glue which is sold in France under the title of "colle liquide et inalterable." This glue being very convenient for cabinet-makers, joiners, pasteboard-workers, toy-makers, and others, as it is applied cold, I think it my duty, in order to increase its manufacture, to publish the process. It consists in taking one kilogram of glue, and dissolving it in one litre of water in a glazed pot over a gentle fire, or, what is better, in the water-bath, stirring it from time to time. When all the glue is melted, 200 grms. of nitric acid (spec. grav. 1.32) are to be poured in, in small quantities at a time. This addition produces an effervescence, owing to the disengagement of hyponitrous acid. When all the acid is added, the vessel is to be taken from the fire, and left to cool. I have kept the glue, thus prepared, in an open vessel during more than two years, without its undergoing any change. It is very convenient in chemical operations. I use it with advantage in my laboratory for the preservation of various gases, by covering strips of linen with it.—*Comptes Rendus and Chemical Gazette*.

THE MEDICAL PROFESSION IN PARIS.—The Medical Directory of Paris, published by *L'Union Médicale*, gives the following numbers to our Parisian brethren:—Doctors of medicine and of surgery, 1837; officiers de santé (an inferior grade), 179; pharmaciens, 423; midwives, 277. From the 1st of January, 1851, to the 31st of December, 1852, there died in Paris 39 doctors of medicine; in the two previous years 64 had died. In the year just elapsed, 88 new practitioners set up in the capital. This year's list contains 15 medical men less than the last. The Directory also gives the numbers in the districts surrounding Paris, and from these statements it would appear that there is a great disproportion between doctors and patients. There are, in fact, less than 500 inhabitants for one medical man; and when it is considered how many of these apply to public institutions, very little is left for individual practitioners. *L'Union Médicale* warns young men from settling in Paris, as the exuberance of professional men is enormous.

## REVIEWS AND NOTICES OF BOOKS.

## A PRACTICAL TREATISE ON INFLAMMATION OF THE UTERUS, ITS CERVIX, AND APPENDAGES, AND ON ITS CONNECTION WITH UTERINE DISEASE. By JAMES D. BENNET, M.D., Member of the Royal College of Physicians, late Physician-Accoucheur to the Westminster General Dispensary, &amp;c. &amp;c. Third Edition.

The favourable opinion which was expressed of Dr. Bennet's work, when noticing the second edition, seems to have been fully borne out, a new one having been called for within a comparatively short space of time. In preparing this third edition for publication, I have (the author states) carefully revised it, and made various additions, which will I trust, render it more complete. I shall have also slightly altered the arrangement of the chapters, with a view to improve the general plan. The principal additions are in the sections upon acute and chronic ovaritis, amenorrhoea, dysmenorrhoea, menorrhagia, and displacements of the uterus. A new incident has also been added, which contributes much to the utility of the work.

Dr. Bennet's views respecting uterine pathology have been so often and so ably advocated by him, that they are familiar to most of the profession, and they have been adopted by a large and influential section of it. "Under such circumstances, I may be allowed (he observes) to pass unnoticed the 'opposition' which I have met with. Believing thoroughly in the correctness of the facts and doctrines which I have advanced, I shall henceforth leave them in the hands of the profession, under the conviction that eventually they must and will be adopted and acted upon by the entire medical community."

In previous notices of Dr. Bennet's work we gave an outline of its contents; here, therefore, we shall confine ourselves to the new matter contained in this edition, and principally to the section upon "morbid menstrual states."

Dysmenorrhoea, according to Dr. Bennet, may exist—1st, "permanently as a constitutional condition, or accidentally and temporarily in connexion with general morbid states." 2nd, it may be the result of the presence of uterine or ovarian disease, or of a contracted state of the cervical canal. "Constitutional dysmenorrhoea is often observed in females whose uterus appears naturally predisposed to congestion, and with whom menstruation is very abundant, and is preceded and followed by a white leucorrhœal discharge. It is met with also when this is not the case." "Accidental dysmenorrhoea may occur in a female who usually menstruates without pain, as the result of over-excitement or fatigue, from exposure to cold, or as the result of some temporary disturbance in the general health."

"Inflammatory dysmenorrhoea. Non-constitutional dysmenorrhoea, according to my experience, is much more frequently the result of inflammatory disease of the uterine organs, and principally of the cervix, than, as is generally supposed, of functional derangement, or of nervous susceptibility. When menstruation, naturally easy, becomes permanently painful, or when naturally but slightly painful, it becomes extremely so, we are warranted in looking for local disease. Such a change does not take place without a cause, and that cause is, generally speaking, inflammation of the cervix or body of the uterus; dysmenorrhoea being one of the most prominent and most ordinary symptoms of that disease."

We may connect with inflammatory dysmenorrhoea that form which has been described under the head of pseudo-membranous, and which is characterized by the expulsion of shreds and casts of plastic lymph from the cavity of the uterus. I believe that the formation of these membranes coincides almost invariably with the present or past existence of uterine inflammation. In other words, I have found, in the great majority of cases of this description, that have come under my observation, that there has been at first inflammatory disease, although the removal of this disease has not always freed the patient from the liability to the formation of the pseudo-membranous casts. M. Pouchet states that in all females, even in virgins, a delicate decidua mem-

brane or cast is formed in the cavity of the uterus at every menstruation, and is thrown out about the tenth day. If so, the deciduous pseudo-membranes of dysmenorrhoea may be considered as merely an exaggeration of a natural condition, but occurring generally speaking only under the influence of inflammatory disease. The expulsion of these pseudo-membranous shreds is always preceded by an aggravation of the uterine suffering, and not unfrequently by terminations similar to labour pains, which are evidently occasioned by the efforts of the uterus to get rid of the casts formed in its cavity.

Physical dysmenorrhoea. Dysmenorrhoea may also depend, as demonstrated by Dr. Mackintosh of Edinburgh, on a physical imperfection of the uterine neck, on contraction of the os internum, or of the canal which constitutes the cavity of the cervix. This contraction may be either congenital or the result of inflammation. The peculiar character of the dysmenorrhoea when caused by congenital contraction, is the absence of any uterine symptom during the interval of menstruation, and a severe agonizing pain for a few hours before the flow of blood appears, either then disappearing or lasting throughout the period, these pains commencing with menstruation in early youth; if they are occasioned by inflammation, there are the same symptoms at the time of menstruation, but there is not the same immunity from uterine symptoms in the interval of the catamenia.

The cause of the pain experienced under these circumstances is evident. The cavity of the non-pregnant healthy uterus, not containing more than about ten or eleven drops of fluid, as soon as the catamenial secretion commences from the lining membrane of the uterine cavity, unless the blood find a free exit through the os internum and the cavity of the cervix, it distends the uterus and gives rise to great pain."

The following forms of menorrhagia are described by Dr. Bennet.—1. "Accidental menorrhagia." 2, inflammatory menorrhagia. 3, menorrhagia from ovaritis; 4, menorrhagia at the dawn and close of menstruation; 5, menorrhagia during pregnancy; 6, menorrhagia after parturition." In the section upon treatment, Dr. Bennet proposes a novel plan of treating certain cases of menorrhagia where "the hæmorrhage persists after the entire removal of the local disease, owing to enlargement of the uterus, to the presence of a small unrecognized polypus or uterine tumour in the cavity of the uterus and its neck, or from the mere hæmorrhagic habit." This consists in plugging the os uteri itself, instead of the vagina. It occurred to me (the author observes) that the usual plan of filling up and distending the vagina by pieces of sponge, or a handkerchief, was a very clumsy, painful, and inefficient mode of opposing mechanical resistance to the exit of blood from the uterus, when its orifice could be so easily brought into sight.

"Acting on this idea, I have, in several instances, brought the cervix uteri into view, and passed inside the os two or three small pieces of cotton, tied to a piece of thread, which I wedged in firmly, covering the whole cervix with two or three larger pieces, left in close contact with it on the withdrawal of the instrument." In most of the cases in which I have resorted to this plan, I have easily arrested the hæmorrhage. Indeed, the modification of the ordinary practice appears to me so simple and so consonant with common sense, that I cannot but think it will be often adopted in severe cases. In the ordinary operation of plugging the vagina, that canal has to be distended by a large mass of sponge or linen, soaked with clotted blood, which often interferes with the functions of the bladder and rectum, is invariably a source of great discomfort to the patient, and is not always efficient; whereas, by the plan I describe, the end proposed is much more effectually encompassed, with scarcely any annoyance to the patient beyond that which the use of the speculum occasions.

Owing to the natural contractility of the cervical canal, and the pressure of the fluids from behind, if the cotton is not well pushed in, it is soon forced out. The plug may be left without renewal twenty-four or even thirty-six hours; but in the latter case it is generally expelled spontaneously. A small piece of sponge may be used, and is more likely to remain *in situ*, owing to its expansion; but as it must necessarily be very small, it is more likely to be permeated by the blood. If sponge is used, great care should be taken to extract the piece passed into the os, to which a small piece of

thread should always be tied, as the os uteri might not be able to expel it alone, owing to its great expansion."

It is scarcely necessary to multiply quotations from Dr. Bennet's treatise; its value is already established with the profession, and the improvements in this new edition render it now the most complete work upon the subject.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, FEBRUARY 23, 1833.

### FREEDOM OF THE PRESS.

It is odd enough that, at this hour of the day, so many readers of our journal should so little understand the nature of our position as regards them and others whom we cannot call readers. Perhaps, however, they understand it better than they care to confess, and only affect a simplicity which does not really belong to them. That subscribers should entertain some definite notions of a *quid pro quo* nature we can well understand; but that persons benefiting by our risks and exertions, without contributing to our resources, should suppose we are in any wise indebted to their patronage is amusing: yet such a strange misconception seems to prevail in certain quarters; a kind of misty idea that some occult influence is wielded by them which we cannot withstand. At such folk we laugh. The opinions of men who can form an opinion we respect, but noisy sounds of *vox et preterea nihil* we value as we value applause from the same source. So let those inflated by exaggerated estimates of their personal importance save themselves the trouble, for we heed not either their warnings or their predictions. Then of those who suppose that we are to be intimidated or diverted from our course by threats of consequences in a different arena, we have the same to say. If collusion with the corrupt be the price we are to pay for the "sweet voices" of those who dispense honours, we are not going to bid for the article on sale. We have been repeatedly accused of unhandsome discharge of our editorial functions, and even indulgence in personalities, when we have been compelled to notice practices which we considered culpable; but how much more open are we to the reproach of having exercised undue forbearance in cases of flagrant delinquency. The unworthy object of popular patronage who openly avows a licentious disregard of all conventional rules of professional obligation, charges us with designs on private character when we denounce his malpractices; and at the same time, those justly indignant because of his proceedings insinuate that we are accomplices if we spare him. We have experienced much vituperation on account of our reproofs of notorious charlatans, as we have blame for our toleration of infamous advertisers. In fact, as we have said, the duties of an Editor are not understood by medical men generally; neither are the limits assigned to his notice of passing events, and the public conduct of persons in office, properly appreciated. It seems to be assumed by many members of our profession that no matter how gross an abuse may be, or how corrupt a practice, no remonstrance is to be offered in print if it has a tendency to implicate individuals; and yet abuses and corrupt practices can scarcely occur without some one to promote them. Important trusts undertaken with solemn promises to discharge them, may be neglected, and stringent oaths may be forgotten or misinterpreted; but if any one hints dissent he becomes "personal," or he assails private character: and perhaps he does, for people cannot

comprehend how a man can be a knave in public and an honest man at home. Be all this as it may, for ourselves we repudiate obedience to any law which would bind us to a tacit acquiescence in the policy or propriety of proceedings which we cannot approve. We do not claim to be the censors of our profession, neither do we pretend to arrogate to ourselves any exclusive title to confidence in our integrity; all we want is to assert our right to enjoy the birthright of us all, Freedom of the Press.

### SURGICAL MEMBERS OF PARLIAMENT.

SOME of our readers will recollect that when, some half score of years ago, the Medical Association of Ireland, with the lamented RICHARD CARMICHAEL at its head, advocated the policy of demanding the right to be represented in Parliament, the conductors of the London medical press lent no aid to its endeavours. A light, however, seems to have broken in on some of them, as appears from the following:—

We are informed that, at the instance of two of the most eminent members of the council, a committee of the council of the College of Surgeons was appointed to consider the propriety of memorializing the government on the subject of conferring parliamentary representatives on the members and fellows of the College of Surgeons. The matter was discussed at many sittings; a memorial was prepared; once the question was carried in the affirmative, but on the proposal to confirm the minute of the previous meeting, the motion was negatived. Thus, for the present, the enlightened members of the council have been defeated; and it appears hopeless to expect that the council will proceed to reconsider their decision. As far as in them lies, the council of the College of Surgeons have had the question of professional parliamentary representation before them, and by them it has been coldly repudiated as an evil. If the representative privilege had been in their hands, and could have been conferred upon the profession, this enlightened body would have refused the boon. We have under our pen the names of the men who, blinded by prejudice and selfishness, defeated the object of the committee. The members and fellows ought to know who have balked them in this matter; but we forbear to publish the names of the men who have committed this grave fault, in the hope that hereafter they may lend themselves to better councils. The motives for the decision we condemn were as miserable as the decision itself. The council of the College of Surgeons were afraid to have their fellows and members entrusted with the power of returning one or more of their own class to represent them in parliament; lest their choice should fall upon improper persons. This was the only argument which could be adduced, and we regret to say it had the sanction of a majority when the question came to the vote. At a thousand points, our profession suffers from the want of such a power and status as parliamentary representation would confer; and the council of the College of Surgeons, instead of seizing the opportunity of pressing for such an advantage, cowers down, from an insane or childish fear lest the surgeons in general practice should return one of their own class instead of a so-called "pure." Such a want of confidence is at once most unjust and ignoble from men who are what they are by the suffrages of the men they suspect and would injure. But happily the question is not entirely in the hands of the council. The members and fellows throughout the country may move in this matter if they please; they may memorialize the government and petition parliament for that which the council have treacherously declined; and if they do so energetically and extensively, we have no fear of their success. With a new reform bill "looming in the distance," medical men may, if they choose, demand to have a specific voice in the legislature. We have laymen presiding over the registration of births and deaths; we have laymen presiding over the Board of Health; we have laymen administering the medical departments of the poor-law; we have laymen presiding over all that relates to lunacy; we have the spectacle of lawyers in plenty in the House of Commons, and of lawyers and divines in goodly proportion in the House of Peers; yet the ruling body of some twelve thousand surgeons deliberately pass a vote of unfitness upon the great bulk of our profession when the question of their having one, or at most two,

representatives in parliament comes before them. We fervently trust this pestilent mischief may be neutralized by the attitude of the profession. Deserted in this matter by their leaders, we hope the members and fellows, who form the bulk of the College of Surgeons, will presently take means to let the council and the government know that they scorn the pusillanimity of the one, and that they claim from the other a boon so which, in this age of intelligence, they are entitled, and which cannot be refused them, if the principle of the representation of educated classes, as well as of mere earth, or bricks and mortar, is to be recognized and grafted into the constitution of this great and free country.—*Lancet*.

## DUBLIN MEDICAL PRESS UPON EXAMINATIONS REAL, NOT VERBAL.

THE DUBLIN MEDICAL PRESS has reprinted our leading article of the 21st January, entitled, "Examinations Real, not Verbal," and although "not concurring in all the opinions offered," our contemporary fully admits that "the period has arrived for a free inquiry into the merits and defects of the present system of examination." The MEDICAL PRESS, however, does us injustice in supposing that we intended to assert that the London University deserves the honour of the "discovery" that *real* should be added to *verbal* examinations; for all we said was, that she has begun prominently to adopt the improvement, and that for this the profession owe her their thanks. We were aware that the Apothecaries' Society—a body constantly but ignorantly and unjustly spoken of by the DUBLIN MEDICAL PRESS—has for years adopted *real* examinations in *materia medica*, in addition to verbal ones, and has not been content with the candidates telling them whence colicium or cubebæ came, and the natural and Linnæan order of the plants, but has likewise required them to know the drugs when they saw them. And we were aware that the microscope has been introduced upon the examination table of the University of Edinburgh, so that there will be less danger of the embryo doctors being unable, when looking down upon it in the instrument, to indicate "the white matter of Schwann," although very accurate as to its exact linear measurement. All that we insisted on was, that this principle should be fully carried out, and that, in addition to the present verbal examinations, the student should be examined in the objects themselves. We trust, for his own sake, that our contemporary of Dublin does not imagine us to be so one-sided and absurd, as to think that anatomy or chemistry, or any other science, can be learned systematically without books, that is, without the assistance of all those who have preceded us, and who have enabled us to master with ease what they discovered with painful toil. All we assert is—and we are certain that every candid man who knows anything of the matter will agree with us—that by the present system a student may pass an examination in anatomy, in chemistry, *materia medica*, and the practice of physic and surgery, with very little knowledge of the sciences themselves, and with merely an acquaintance with the words which represent them; and that the prevailing system of examination fosters this mistaken direction of the pupil's industry. We rejoice to learn from our contemporary that the Colleges of Surgeons of Dublin and of London are at this moment engaged in considering this subject; and we trust that the result of their deliberations will be the needed reformation. We are not of the number of those who love great and sudden changes. We have a strong conservative bias; and we fully sympathise with those who have been actually engaged as examiners for years, who have adopted many improvements themselves, and who daily see where other changes might be effected were it not for circumstances which they cannot singly control. But, on the other hand, like every one who watches the progress of our Anglo-Saxon institutions, we know that all of them require public supervision and public discussion. However annoying it may be to the actual workers to be overlooked and scrutinized, yet suggestions *ab extra* are useful, and often quicken into vigorous life much that might have remained dormant without such a stimulus. Our institutions demand *progress* as well as *stability*: two principles which must work together in our medical corporations, if they are to live and grow, to rise and not to fall. We would ~~remind~~ then, that what we conceive to be imperatively wanted is *an addition to the prevailing system*. Let the present plan of systematic examination in words be still carried out, but let there be likewise an examination of the practical knowledge of the candidates in the things themselves. Many of the present staff of examiners, who are highly capable from long experience and ripe acquirements

of testing the general requisitions of young men, may neither be willing, nor able to act as demonstrators of anatomy, or manipulating chemists. But surely there can be no insuperable difficulty in appointing for this purpose examiners who are engaged in the daily practice of anatomy, of chemistry, *materia medica* and botany; and who therefore being up to the actual state of their sciences, would examine the candidates on the dead body, and with tests, retests, drugs, and plants previously to their verbal trial. On the other hand, it is possible that none might be more fit than the present examiners to investigate, at the bedside of the patients, the actual acquaintance of the pupil with manipulations, diagnosis, and treatment.—*Association Medical Journal*.

When have we "ignorantly and unjustly spoken of the London Apothecaries' Company?" We have taunted the Practitioners of England with their want of self-respect in accepting "medical honours" from a joint-stock drug company. That's all.

## MEDICAL LIFE IN LONDON.

THE HUNTERIAN ORATION.

London, February 14, 1853.

THE quiet of the Hunterian Museum this week has been disturbed by the removal of preparations and the din of hammers preparatory to the Hunterian Oration of Mr. Bransby Cooper. The theatre, by some want of arrangement as to some old houses next door, has been rebuilt for no earthly purpose, the same as before. New timber, the gold mace, injected testicles, and the Guy's men in the gallery, "thick as leaves in Valombrosa," affording a pleasing variety to the Hunterian of last year. Mr. Bransby Cooper appeared quite up to the mark. We were, however, grimly disappointed with the whole affair, not hearing any one of the excellent old jokes that erst kept us all alive at Guy's. Lord John Russell was expected every moment, it is true, and every body was on his good behaviour. The Oration, from beginning to end, was of the most elementary and simple character, the excellent lecturer commencing by deprecating a mere laudatory eulogium on Hunter, but which one could not help feeling he himself fell into insensibly as he went along. The Hunterian Oration, he well said, should take a simple practical shape, and, *erectis auribus*, every one waited for what was to follow. Warming with the dignity of his subject (written by the way in a large round hand), Mr. Cooper spoke of Hunter as the great "Prophet," as Professor Owen loves to call him the great "Saint," of Surgery—a prophet, might we say, with no honour in his own country till dead.

The first thing studied by Hunter (continued the lecturer) was the identity of phenomena engaged in the process of renewing broken shell, broken bone, and grafting in plants; in other words, organic *lesion*. Percival Pott, too, about this time, suggested many improvements that more or less influenced Hunter, "repudiating" the actual cautery and other violent measures, and simplifying surgery.

Here the lecturer reviewed old Hunterian Orations, and applying himself to the younger (Guy's) portion of the auditory, held up Hunter again as a striking instance of what industry and energy might achieve. After much consideration of the subject, Mr. Cooper had arrived at the conclusion, that it was as a "Naturalist" John Hunter would be ever known; his museum bearing ample testimony, as we, in common with every body else, must concede, to the untiring energy of his mind; but of all this order and system in his mode of study, we must look on it as moonshine. Without much education, but indomitable industry, the great subject of the Oration had performed miracles.

Mr. Cooper next spoke in eloquent terms of the difficulties encountered by Hunter. We half-feared, however, from his manner, that the lecturer was here going to make out Hunter a gold medal man or wrangler at Oxford. If Lord John Russell had arrived, we should have trembled for the result. Hunter's "slender means," we were told, however, after much discussion on the subject, "prevented him gaining any but the most ordinary branches of education." Mr. Cooper was free to confess, however (and it seemed to gain the assent of the whole Examining Board, winking through the haze of the lecture-rooms), that a college education was little or no use; that from the books of the classics, as he sententiously expressed it, the mind comes with "less freshness" to the great Book of Nature—a doctrine, we believe, that could be propounded nowhere but in the London College of Surgeons.

Hunter, said Mr. Cooper, wished his museum to be a "picture of the entire created universe." The man, the oak, and the mountain, are all mere modifications one of the other, and John Hunter wished to bring all creation into his collection. Here one might have wished, too, the lecturer had drawn it mild, but on he went, forgetting the perturbations of the solar system and volcanoes not shown in the museum. "Plants," with much gravity, it was stated, were not the same as animals, nor animals, perhaps, identical with minerals (one thought insensibly of "gods and little fishes;" no smile seemed, however, to light up the darksome shadows of the audience, or the snow storm out of doors). Plants, however, stand between animals and the mineral kingdom, it was mentioned, with some other rather A B C facts we hardly recollect.

The lecturer next spoke of carbonic acid gas, the decomposition of which, he stated, to be the most complex and troublesome of the processes in the laboratory, but every moment effected by the agency of life and living tissues; the beautiful relation of water plants to fishes, and both to the keeping of water from growing putrid, was here forgotten. One of the most beautiful of the results of Hunter's observation (natural history at the time of Hunter), was what the lecturer called a "barren waste," neither the classification of Linnæus, nor any of the phenomena under the microscope, being understood. Hunter studied, however, the animal and vegetable fluids; blood and sap in plants, he considered the same in their nature and uses; and modern physiology, said Mr. Cooper, had further shown the truth of Hunter's views, as the albumen and fibrin of the vegetable and animal kingdom were identical. Hunter's dogma of healing by the "first intention" grew out of his belief, that the blood was endowed with life, and extravasated between the lips of a wound, it partook of the life of the parts. Several preparations from the museum were here exhibited bearing on this point, especially the well-known and wonderful preparation of Hunter's of a human tooth, implanted and growing in the head and comb of a cock; and again, the spur of a cock, transplanted into its comb, not only living, but apparently growing in its new situation. These preparations are "household words" in physiology.

The next subject brought under consideration was motion in plants and animals. All kinds of so-called motion in plants, the lecturer contended, were owing to elasticity, true vital motion beginning in animals. Here one could not help thinking of the curious circulation, under the microscope, in the vessels of plants, impregnation of pollen, &c., not due to elasticity. Motion in muscles was very fully and in an elementary way next explained; the lec-

turer rather *naively* stating that Hunter was not probably aware of striped and unstriped muscles as seen in the microscope. He was quite aware of the characters of elastic tissue which he studied in the *ligamentum nuchæ* of long-necked animals. Want of time prevented the lecturer giving us all the characters of "elastic tissue;" but he satisfied himself with stating Mr. Quckett's discovery of striped marks in all such parts.

Nature, Hunter said, used elastic tissue to economise vital force, and in this way it was most useful. The lecturer next recapitulated about elasticity in plants, and skimming along in rather "ducks-and-drakes" fashion, lighted on Digestion, the shadows of evening still thickening, all buried in the penumbra of four wax candles. The "stomach," the lecturer stated, *suo periculo*, was the great distinctive mark between an animal and a plant—an alderman, for instance, and a banyan tree.

The elementary facts in the process of digestion were next entered into, much to the discomfort apparently of Dr. Paris, Dr. Addison, Professor Owen, and others. Animals, it was said, moreover, seize their food as contradistinguished from plants, the "apparatus of prehension" being very varied, the "ways and means" of eating singularly adapted to each tribe of animals. The carnivora, Mr. Cooper was inclined to think, could not manage with herbivorous molars, or herbivorous molars could not serve the hyena or tiger. We next expected the old fact of man being omnivorous, especially as the Board of Examiners were to dine at the Freemason's Tavern; but in place of this interesting statement, and something about Calipee and Calipash, an extract followed from Hunter on whalebone. As also connected with the function of digestion, the lecturer next spoke of "trituration" in the stomachs of some animals, mullet and other fishes, the gizzards of birds, and by some conjunction disjunctive, of the milk of the pigeon.

The lecturer's emphasis on some of poor Hunter's indifferent English was here a little too much for the gravity of the audience, and a beamy smile ran round the theatre. The general function of glands next came in review, their chief use, it was stated, being to change the ingesta and minister to the maturation of chyle and separation of chyme; the singular function of the liver, spoken of by Bernard, and like Hamlet in the rural play, the kidneys were here left out. The absorbents were next considered, which were not known, it was hinted, till the time of Hunter. The lecturer also deprecated the mistaken notion of the ancients, who thought, absurdly enough, that veins and lymphatics were nearly the same. (*Qu*: Were the ancients quite so much out as Mr. Cooper would have them?) Hunter, he went on to show, first demonstrated the nature of absorbent glands; this the lecturer fully showed, and having exhausted his subject, turned to the "ways and means" of getting children; or, as Mr. Cooper stated, it was sometimes called procreation.

The periodic enlargement of the testis in some animals was explained, but the ovular theory of menstruation and conception left out; and the excellent and accomplished lecturer wound up the more immediately professional part of the subject by a sort of insect-requiem on the short-lived character of some ephemeral insects, born but to die, but all procreative organs; in which, in fact, they were not unaptly studied.

Some few words in form of *éloge* were spoken, according to immemorial custom, relative to the several more prominent men who had died through the year—remarks, in the propriety and good taste of which every one seemed

agreed. Hats and umbrellas were now in requisition; but like the postscript of a lady's letter, the great purpose of the Hunterian Oration remained yet untold—namely, to bespeak government support for the college and museum: the latter having been so faithfully "taken in" and guarded since Hunter's death, and the college all that human wisdom could make it.

The "bane and antidote," however, had somehow got into the theatre, for distributed to every member was a pamphlet, in which we read these words:—"The London College of Surgeons grants no legal right, it constitutes the lowest professional qualification in the kingdom, sends forth more unqualified practitioners, inflicts more public injury, and encourages idleness among students, to a greater degree than any of the medical corporations of the kingdom." Its practitioners, before 1815, with the college twenty guineas' worth of diploma paper, it hints, must have been babies in the nurses' arms; and it serves as the cheap shop for rejected candidates from Ireland, who here find "immediate admission." The very eminence of the Examining Board is the "great obstacle to medical reform." So far the pamphlet addressed to the Home Secretary. Now the concluding words of Mr. Bransby Cooper:—"The government, recognizing with a liberal and discriminating spirit, the essential usefulness of the *corporate medical and surgical bodies*, had munificently granted a large sum of money towards the completion of the building, and enabled the college to increase the capabilities of the institution, so that its resources (of cheap diplomas?) might be progressively developed; to a degree, the influence of which (to many a man's cost) will be felt by every branch of the medical profession." So ended the Oration, and the evening was wound up with a jollification worthy of the ancient and money-making corporation. The *Times* newspaper speaks of colleges in Ireland, and the difficulties to be contended with, of ignorance, as very marked in all your faculties; but with an opposition shop like the College of Surgeons, London, underselling the College in Dublin—till there is an equalizing of curricula, and a surgeon at both sides of the Channel, like a carpenter or sawyer, being something definite, and everywhere the same, it is but an insult to the memory of Hunter to speak of the dignity, unanimity, or respectability of the profession.

FRAUDULENT TRAFFIC IN DIPLOMAS.

AN article appeared in the *Lancet* of January 8th, headed "Unqualified Practitioners and alleged Forged Diplomas." I regret that I was not at once aware of it, and trust you will allow me, even at this distant date, to make a remark or two on a communication in which my name so conspicuously figures. Your readers would naturally infer that the article had reference to an altogether unqualified practitioner. I beg, therefore, to state that, I qualified as L.S.A. in 1826, and that I had been engaged in general practice twenty-four years (the last seventeen in the same town), when ill-health compelled me to relinquish it. As to the documents I then obtained (and for which I paid £51), no doubt was entertained of their genuineness, either by myself or my friends. The astounding information contained in the letters, now so widely circulated, first awoke my suspicions, and led me to fear I had been the dupe of a set of accomplished impostors. My personal friends are already acquainted with the facts of the case. I shall not be expected to detail them here, especially as your own pages show that I do not stand alone, but that spurious diplomas have, within the last few years, been issued to a considerable extent by persons professing to be officially connected with the University. I learn from other sources that such diplomas have been palmed upon highly respectable practitioners holding other qualifications. To some, the annoyance arising from individual exposure might be ex-

treme; to myself, having altogether retired from practice, the matter is of less importance, and I care not how soon the title created by such documents be severed from my address. Mr. James Trull of Bath in *Lancet*. [The straightforward manner in which Mr. Trull has answered the charge is creditable to him; at the same time we think it but just to the profession that the names and addresses of the parties who imposed upon our correspondent should be given. It is indeed time that the traffic in these sham titles should be abolished.—Ed. L.]

JAMES MARTIN, M.D.

TREATMENT OF HYDROCELE BY GALVANO-PUNCTURE.—S. Vivanelli relates (in *Gazetta Medica Italiana Toscana*) three cases of hydrocele cured by, from seven to eleven applications of galvano-puncture, for five or six minutes at a time, the needles being introduced into the extremities of the tumour. There was an interval of one or two days between the application of the needles.

### ASSOCIATION OF MEDICAL OFFICERS OF DISPENSARIES AND FEVER HOSPITALS.

We request that those Members who are of opinion that a General Meeting of the Association should be held in Dublin, will direct the Secretary, Dr. Waters, Parsonstown, to attach their names to the Requisition convening such Meeting, and state the time when they think it ought to take place.

The subjects proposed for discussion are—

- 1st. The working of the Medical Charities Act.
- 2nd. The insufficiency of the present salaries.
- 3rd. The transfer of Medical Salaries, either wholly or in part, from Poor's-rate to the Consolidated Fund.
- 4th. The establishment of District Hospitals.
- 5th. Such other matters as may be connected with the advancement of the interests of the profession.

WM. KINGLEY, M.D., Chairman.

J. MORRISON, M.D., Treasurer.

J. WATERS, M.D., Hon. Secretary.

### AN EXAMINATION OF THE MEDICAL FACTS IN THE CASE OF THE QUEEN *versus* W. B. KIRWAN, &c.

By T. G. GEOGHEGAN, M.D.,

Fellow and Professor, Royal College of Surgeons, Surgeon to the City of Dublin Hospital, &c.

(Reprinted from the DUBLIN MEDICAL PRESS, with Additions by the Author.)

Dublin: Fannin and Co., 41, Grafton-street.

London: John Churchill, Princes-street, Soho.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, and 64, Dame-street, Dublin (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

G. O. and Co. ARE ALSO SOLE AGENTS FOR THE SALE OF H. NEWSON'S PATENT WIRE TRUSS, WHICH IS NOW RECOMMENDED BY THE FIRST MEDICAL AUTHORITIES.

### THE COMPOUNDING DEPARTMENTS AT

#### G. O. AND CO.'S MEDICAL HALLS

are separated from the Retail, to prevent interruption and irregularity, and obtain the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.  
G. O. and Co. continue to be supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

### TO SURGEONS, DISPENSING CHEMISTS, ETC.

SULPHATE OF QUININE, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, capsuled, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,  
Chemical Works, Trinity-street, Southwark, London.

### UNIVERSITY AND KING'S COLLEGE, ABERDEEN.

THE Examination of Candidates for the Degree of M.D., will be commenced on Tuesday, the 12th of April, and will be continued daily till finished; immediately after which the Graduation will take place. Those intending to become Candidates are requested to forward the necessary documents, on or before Friday, the 25th of March, to the Professor of Medicine.

#### REGULATIONS.

Practitioners who possess a Licence or Diploma from any of the Royal Colleges of Physicians or Surgeons, or from the Apothecaries' Company, and who have been engaged for at least five years in the practice of Medicine, will be admitted to examination on producing their Licence or Diploma, along with satisfactory evidence of good moral character, and of having studied the Classics at a University or at an Academy of acknowledged reputation.

Practitioners who commenced their Medical Studies before October, 1840, and who have not been in practice for five years, will be admitted to examination on producing, along with their Diploma, evidence of attendance at the Classics, of moral character, and of having been engaged in the Study of Medicine for four years, during which they must have attended, in a recognized School of Medicine, the following courses of Lectures:—

#### SIX MONTHS' COURSES.

Anatomy	...	...	Two courses.
Chemistry	...	...	One course.
Materia Medica	...	...	One course.
Surgery	...	...	One course.
Institutes of Medicine and Physiology,	...	...	One course.
Practice of Medicine	...	...	One course.
Midwifery	...	...	One course.

#### THREE MONTHS' COURSES.

Dissections	...	...	Two courses.
Practical Chemistry	...	...	One course.
Medical Jurisprudence	...	...	One course.
Clinical Surgery	...	...	One course.
Botany	...	...	One course.
Clinical Medicine	...	...	Two courses.

In addition to the above, Candidates must have attended for two years the Wards of a Hospital containing one hundred beds, and during three months a Shop or Dispensary for the compounding of Medicines.

ANDREW FYFE, M.D.,

Professor of Medicine.

Aberdeen, February 18, 1853.

### ASSOCIATION MEDICAL JOURNAL.

Edited for the

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION,

By JOHN ROSE CORMACK, M.D.

FRIDAY, February 18. *Principal Contents*—1. College of Physicians of Edinburgh and the Diploma Stamp-Tax. 2. Court Martial on Mr. Umphelby. 3. Medical Society of London and the Science of Physiology. 4. Verdict of Man-slaughter against Mr. Hicks. 5. Report of Reading Pathological Society, by T. S. Little, Esq. 6. On Distichiasis, by White Cooper, Esq. 7. Identity of Erysipelas and Puerperal Fever, by R. Elsdale, Esq. 8. Hemiplegia from Exposure to Solar Heat, by W. H. Ashley, M.D. 9. #### ON DISLOCATION OF THE METATARSUS.

By JOLLIFFE TUFNELL, F.R.C.S., M.R.I.A.

MR. PRESIDENT,—The case which I purpose detailing to the Society this evening is one which, from its rarity, will, I trust, prove interesting to the members. It is that of luxation of three of the metatarsal bones of the foot downwards and backwards, the result of external violence. I believe that the case is almost, if not wholly, without parallel, at least I am not aware of any similar one being on record; and in proof of this assertion, I may quote from the last edition of Sir Astley Cooper's work on "Dislocations," by Bransby Cooper, in which he says:—"The metatarsal bones I have never known luxated; their union with each other and their irregular connexion with the tarsus prevent it."

For the opportunity of witnessing the case which I am about to describe, I am indebted to my friend Dr. Dolmage of the 7th Dragoon Guards, in whose regiment the accident occurred, and in the following manner:—T. D., æt. 26, a middle-sized, well-made man, was returning off duty to Portobello Barracks, Nov. 30, 1851. He was walking his horse near the side of the canal, when suddenly, the road being very slippery from frost, the animal came down upon his off side, falling with his whole weight upon the patient's right leg and foot, crushing it against the ground. The horse rose upon his legs, the patient remaining in the saddle, but from the agony he was suffering, having no power over the animal, who reined back into the canal, his hind legs dropping in off the bank. In the struggle which ensued, the patient became disengaged from the saddle, and was left floundering in the water, the horse making his own way up, and the patient being dragged out. From the spot where this occurrence took place to the hospital to which he was conveyed, is but a short distance, and he was seen by Dr. Dolmage in a very few minutes, and before any considerable degree of swelling

had taken place. The foot was curved inwards and bent, a large bony projection rising on the tarsus with a sharp edge anteriorly, overhanging the metatarsal bone of the second toe. In the sole of the foot, deep under the plantar muscles, a hard bony projection also could be felt.

Reduction was attempted by placing the patient on his back, fixing the pelvis, and flexing the leg upon the thigh. Extension by pullies attached to the phalanges of the great and adjoining toes was then made and persevered in for a considerable time, during which every possible movement likely to favour restoration of the parts by flexion of the metatarsus upon the tarsus was resorted to, and leverage also made directly upon the dislocated extremity of the metatarsal bone of the great toe, where projecting in the sole by means of a ruler applied to it, and drawn upwards and forwards, whilst the clasped hands of a strong assistant placed upon the instep, held that part downwards and backwards. As great force as it was considered justifiable to employ, was expended in the effort at reduction, but not the slightest alteration in the position of the bones was effected. Considerable effusion and ecchymosis followed, the latter extending up almost to the knee. Leeches, fomentations, &c. &c., were prescribed, and the ordinary treatment for violent contusions had recourse to. Under this treatment swelling subsided, and on the 14th of February (ten weeks from the accident), the foot presented the appearances represented in the cast,\* which was taken this day, and during which time the patient had been confined entirely to bed by suppurating bubo in the opposite groin.

All swelling and thickening were now gone, the outline of the tendons and every portion of the extremity being most accurately defined. In its general aspect, the foot somewhat resembled a case of pes equinus, being considerably shortened and arched upon its inner border, the distal extremity of the metatarsal bone and first phalanx of the great toe being adducted, the last phalanx at the same time pointing somewhat outwards. The instep bore a

\* This cast is in the Museum of the Royal College of Surgeons, Ireland.

natural appearance from the malleoli to the extremity of the internal cuneiform bone, which projected in a sharp point anteriorly, raising the integument which was stretched over it, white and glistening, like a tightly bent knuckle; and from the outer border of the cuneiform bone ran an evident ridge, marking the division between the tarsus and metatarsus, and defining the line for Hey's amputation of the foot.

In consequence of the bubo in the groin, the patient had made no effort to walk; but upon the few occasions on which he had tried to use the limb supported by crutches, he had found a total inability to move otherwise than on the heel, in consequence of pain of a burning lancing character being produced in the sole of the foot whenever he attempted to throw any weight upon the toes, and place the plantar structures on the stretch.

I saw this man subsequently in June, when I obtained a second cast of the foot. It had now become more inverted, and the projection in the sole was less evident, having been rounded and partly removed by absorption. He walked freely with a stick, bearing his weight on the outer border of the foot, as in a case of talipes varus, but he could not move or make any effort when the foot was placed flat upon the ground, from the same burning sensation already alluded to, and which he described as resembling the feeling that might be imagined to result from attempting to walk in a very tight boot, with a marble under the sole of the foot.

Dr. FLEMING thought the case related by Mr. Tufnell one of exceedingly great interest, and the cast by which it was accompanied admirably illustrated the deformity produced by the dislocation described in his valuable paper. It was, he believed (and his friend Mr. Adams who sat next him entertained the same opinion), a case altogether novel as regarded the nature of the injury, and nothing of a precisely similar kind would, as far as he knew, be met with amongst the cases of dislocation on record. It brought to his recollection a case which he witnessed in the person of a medical gentleman, who met with a dislocation of the internal cuneiform bone. The accident, he believed, occurred on horseback. The horse took fright and ran away; the rider was thrown off, and his foot being caught in the stirrup, the internal cuneiform bone was dislocated, producing a very remarkable kind of deformity. It resembled in appearance the "flat foot," as it was termed, met with in strumous females. Every effort was made to reduce the dislocation, but without success. However, the gentleman was able to make tolerable use of the limb, although he suffered now and then from those neuralgic pains which accompany injuries like that in Mr. Tufnell's case.

The PRESIDENT remarked, that in a case mentioned by Dupuytren, where there was dislocation of the fourth and fifth metatarsal bones, the latter were restored to their natural relationship by means of extension.

Mr. TUFNELL said that the extension in his case was made by pulleys, and kept up for nearly an hour without the slightest effect. In some cases also which had been in the Richmond Hospital, described by Dr. R. W. Smith, the dislocation was not reduced. In those instances the displacement was upwards and backwards.

The PRESIDENT observed, that the difficulty of reducing these bones of the foot must necessarily be very great. In a case which occurred some years ago in the City of Dublin Hospital, where the phalanges of the great toe were dislocated, they completely failed in reducing the dislocation.

Mr. ADAMS said that Dr. Fleming had truly represented his opinion, that the case adduced by Mr. Tufnell was unique, and that, as far as he knew, that nothing precisely similar had been recorded. The three examples of displacement of the metatarsus reported by Dupuytren, and the two additional ones described by Dr. R. W. Smith, were all dislocations of the metatarsus upwards on the dorsum of the tarsus, which we know to be the reverse of what had occurred in Mr. Tufnell's case just related. In this last case, the instep seemed preternaturally high and the sole hollowed; whereas in the five other examples of dislocation of the metatarsus upwards, the instep seemed

low, and the sole of the foot, as Dr. Smith had shown, remarkably convex. There is one more point of difference which perhaps ought here to be adverted to—namely, that Mr. Tufnell's case seemed to be a simple dislocation downwards of the metatarsus; whereas in Dupuytren's and Smith's cases, the internal cuneiform bone retaining its connexion with the bases of the metatarsal bone of the great toe, was dislocated upwards in company with the metatarsus. As to the surgical treatment of these injuries: if we permit ourselves to draw any inference from the few cases before us, we may conclude, from the result of Dupuytren's first case, that dislocation of the metatarsus upwards may be easily reduced, if the accident be seen early and properly treated; but that if the case be neglected for three weeks, as was the case in the second example of this accident met with by Dupuytren, that then the reduction of the dislocation will be found difficult or impracticable. As to the means which were used or omitted in Dr. R. W. Smith's cases, I believe nothing is accurately known. The value of these two facts consist in the accurate post-mortem examination which was instituted. As to the surgical treatment in the case of dislocation of the metatarsus downwards, we know of but one (Mr. Tufnell's case), and although the most energetic efforts were made to replace the bones a few moments after the accident had occurred, still these means failed; however, it is reasonable to hope that the patient will in time (as occurred in Dupuytren's case) regain fair use of his foot in progression. There is one practical point we should attend to, should we reduce the dislocation of the metatarsus, whether the displacement be upwards towards the dorsum of the foot, or downwards (as in Mr. Tufnell's case)—namely, that there is great mobility of the bones of the foot to be expected after the reduction of the dislocation. Dupuytren found that in the case of the patient in whom he was happy enough to reduce the dislocation, that the foot was found immediately afterwards very moveable in the metatarsal line of junction of the bones. He therefore found it necessary to enjoin absolute repose and to apply bandages, but ultimately recovery was complete.

Mr. TUFNELL.—In the course of six months after the injury, he gradually brought himself to walk on the outer border of the foot, and in June, 1852, when I last saw him, he could walk pretty well with the aid of a stick.

#### ACADEMY OF SCIENCES OF PARIS.

REDUCTION OF OLD LUXATION OF LOWER JAW, REDUCED BY M. STROMEYER'S APPARATUS.

By M. BOUSSON,

Professor of Clinical Surgery to the Faculty of Medicine, Montpellier.

EXAMPLES of reduction of old luxations of the lower jaw are still by no means common; so also are cases in which Stromeier's apparatus have been used. Adding a new and certain mode to those which science already possesses, will encourage practitioners not prematurely to renounce their attempts to reduce old luxations of the lower jaw. A new and progressive view of the mechanism of old luxations has been taken, and the assumed difficulty in reducing these luxations depends more upon the imperfection of the instruments used, than upon the obstinacy of the luxations themselves. Now-a-days, the application of the anæsthetic agent permits us to go further than we otherwise would, and multiplies our chances of success, by allowing us to act on the luxated bone in the suitable direction, and with proper instruments.

Case.—Françoise Arnaud from St. Lamert (Gard), entered the Hospital of St. Elai, in Montpellier, on the 16th of February, 1852. She is aged 31, has always enjoyed good health, and is of lymphatic temperament. When interrogated as to her previous life, she mentioned a circumstance which appeared to have made but slight impression on her, but which proved that she was disposed to luxations of the lower jaw. She stated that about five years before, after an intense and prolonged fit of yawning, she was seized with sudden immobility of the lower jaw, accompanied by great distension of the mouth.

Ignorant of what ailed her, she endeavoured of herself to restore parts to their natural position; she pressed her chin firmly against her breast, and suddenly applying both hands with all her strength, succeeded in causing the appearances mentioned to disappear. This first luxation, for which the patient had not consulted a surgeon, was not followed by any disagreeable consequence.

On the 20th of December, Frangoise Arnaud, when endeavouring to take an unusually large bite of a pear, which she was eating, found her jaws widely distended, and as firmly fixed and immoveable as they had been on the former occasion; but this time these symptoms were accompanied by severe pain in the temporo-maxillary articulation, extending towards the temple and orbit. The patient, who lived in a village in the department of Vaucluse, sent for the nearest medical man. As speaking was accompanied by the greatest suffering and difficulty, she neglected to inform this practitioner concerning her former accident. On this account, perhaps, mistaking the nature of the case, and believing it to be a nervous affection, he made no attempt at reduction; he confined himself to directing the application of ten leeches behind each ear and to the fossa parotidea; a warm poultice to be afterwards applied. Of course, no alleviation of the symptoms followed this treatment, which was blindly persevered in. About three weeks after the accident, the patient, disappointed at finding herself still in the same state, consulted another medical man, who unfortunately entered into the views of his confrere, and thought fit to continue the application of leeches, which had been discontinued for some time. Perhaps the inflammatory symptoms, or the severe pain, accompanied by swelling of the surrounding parts, suggested the idea of this antiphlogistic treatment, which was actively persevered in; but the patient's own assertions are not favourable to this supposition. The nature of the lesion was completely misunderstood, not the least attempt having been made at reduction.

On the 18th of February, Frangoise Arnaud decided on going to Avignon for the purpose of seeking relief from the misery which she endured. The surgeon consulted, at once perceived the case was one of complete luxation of the inferior maxilla, and immediately attempted the reduction of the bone. The manœuvres attempted not being sufficient to disengage the condyles, the patient was bled, and belladonna friction directed over the region of the masseters, for the purpose of overcoming muscular resistance. The patient returned to her village, when these frictions were continued for some days. The reduction was again attempted, and, for the purpose of acting more strongly on the jaw, the handle of a knife was introduced into the mouth between the dental arches, to serve as a lever to depress the bone. The loss of three molar teeth of the upper jaw, and one of the lower, on the right side, followed these attempts; at the same time, not the least advance was made towards the reduction.

Frangoise Arnaud again returned to Avignon, to seek the assistance of M. Pamard. My confrere and friend attempted the reduction with his usual ability, but his efforts were unavailing, for he found it impossible to dislocate the maxilla from its new position. M. Pamard, who had not at his disposal M. Stromeyer's apparatus, thinking that the patient would find every applicable resource at Montpellier, sent her to me. She presented the most evident symptoms of luxation of both condyles of the jaw. The mouth was open; in front, the jaws were two-thirds of an inch apart; this distance diminished towards the molar teeth, which were almost in contact; the lower projected also two-thirds of an inch beyond the upper. The teeth did not correspond, the lips could not be approximated, and very considerable difficulty attended any attempt at articulation. The patient could take none but liquid food. In front of the ear, on a level with the condyles of the inferior maxilla, there was a depression; the temporal muscles were tense, and formed a well-marked projection; the coronoid processes could be felt distinctly projecting forwards, by introducing the fingers into the mouth. The general state of the patient was favourable;

everything considered, she had suffered but little. She felt slight pain on a level with the luxated articulating surface, and in the surrounding textures. No doubt could exist of the nature of the lesion, so on the day of the patient's admission into hospital, I attempted the reduction. My attempts were made in the usual manner, and in the way most likely to disengage the coronoid processes from their relations to the malar bones. For the better carrying out of my intentions, the patient was seated on a low stool; this was done that the more efficient pressure might be kept up on both sides of the jaw. The only effects of these attempts were tiring myself and distressing the patient. Therefore I resolved, on the following day, to apply Stromeyer's apparatus, as I considered it the only means by which the organized adhesions of the condyles and the muscular resistance could be overcome. This instrument, made of steel, is composed of two blades, terminating at their anterior or buccal extremities by a plate, to which is given the parabolical curve of the dental arches; they should be well padded with chamois leather. These blades articulated in their middle without crossing. This articulation presents a *point d'appui*, by which the surgeon acts (as with a lever of the first order) upon the opposite extremities of the blades, which blades are kept separated by a spring. Pressure, by approximating the anterior extremities of the instrument, necessarily separates the posterior ones, and by that means allows us to make use of this simple mechanism so as to act on the dental arches, between which the blades, when closed, are carried. By this contrivance, the depression of the lower jaw is effected.

To act more gradually and forcibly, pressure can be used by means of a screw and nut; the end of the screw fits into a depression on the lower blade, and is retained there by a screw, the other end goes through a hole in the upper blade, and the nut, screwed down from above, presses on it, and so closes them. The instrument should be introduced into the mouth closed. When it is properly adjusted, the nut is screwed down as far as it is desirable to separate the parabolic plates; and after the reduction, as it would be painful to withdraw the instrument open, the screw which acted on the lower extremity of the pin, should be loosened; the spring then acts, and quickly brings the posterior extremities of the instrument to their original distance of separation, and of course closes the instrument at the other end, so that its removal from the mouth is easy.

I borrowed the instrument described above from the Museum of the Faculty, and on the 18th of February, at the morning visit, I applied it to the patient. I immediately entertained a high opinion of its efficacy, for I could separate the molar teeth, which I was unable to do with my thumbs; but this action was accompanied with very great pain, and by violent contraction of the temporal and masseter muscles. I then believed it prudent to suspend the operation until the patient was under the influence of chloroform, when I could easily overcome the muscular resistance, and when the patient should be spared needless suffering. The operation was deferred till the end of the visit.

*Operation.*—Frangoise Arnaud was brought into the operating theatre; I placed her in the horizontal position, and put her under the influence of chloroform. At the end of three minutes, insensibility and muscular relaxation were apparent. I then introduced Stromeyer's apparatus into her mouth, and having forced the anterior blades, approximated, between the molar teeth, I separated them by pressure. The inferior maxilla sunk, and yielded little by little; when I considered this separation sufficient, I entrusted the instrument to an assistant, and having made pressure backwards and downwards for a little time, both on the body and on the blades of the instrument, the bone sunk into its normal position. Immediately the instrument was removed from the mouth, and it was at once perceptible by the correspondence and approximation of the dental arches, that the reduction was then regular and complete; the mouth was shut, and the lips met naturally. This result was obtained without the

least pain, and unknown to the patient, who awoke delirious and astonished at finding herself thus instantaneously cured.

The dressing consisted of a bandage, and compresses dipped in cold water, applied to the temporo-maxillary region. For a day or two, there was slight pain in the part, but neither inflammation nor swelling supervened. The patient was put on liquid diet, and recommended not to open her mouth widely. On the third day, the pain was completely gone; the motions of the jaw were perfectly free, and regular nourishment was permitted. The patient remained in hospital for a few days, that there might be no doubt as to the permanency of her cure.

On the 26th, the patient possessed complete power over the jaw, and could masticate solid food. She then left the hospital.

I shall add a few observations on this authentic case. Books on surgery contain but three or four cases of reduction of old luxations of the lower jaw. The greater number of surgeons direct that if the luxation has existed more than one month, no attempt should be made at reduction. In a case of the same kind, when M. Stromeyer, for the first time used his parabolic plates, the accident was not of a month's standing. In this second case which I furnish, more than twice the specified time had elapsed between the time of the accident and the reduction; still this instrument proved as efficacious and prompt as in the first case. These results of our observation, facilitated by the intervention of chloroform, tend to increase the extent of surgical mechanism applicable to old luxations, especially the one which now occupies us. By these considerations, I conceive the following conclusions are justifiable:—That reduction of luxations of the lower jaw, are not only practicable but easy two months after the occurrence of the accident; that the most approved mode of operating is with the lever and parabolic plates; that the application of anæsthetic agents increases our chance of success in the operation. S. J.

#### PRESENCE OF SUGAR IN THE URINE OF EPILEPTICS.

By MM. MICHEA and ALVARO REGNOSO.

THE urine of epileptics after an attack, contains sugar, as we have distinctly proved by a number of experiments, except that all the usual tests will not suffice for its detection. Caustic potash, which usually shows it in diabetic urine, does not produce any reaction in that of epileptics. The saccharometer is also useless, as it is not sufficiently delicate or convenient. The best and most decisive proofs are fermentation and the action of Barswell's fluid. So that the latter may furnish certain and undoubted results, certain precautions must be taken. The urine must first be treated with acetate of lead concentrated, and then the fluid being added, the whole is boiled. Without these indispensable precautions, so as to deprive the urine of its organic matter, the presence of sugar cannot be sufficiently proved, even where it produces reactions capable of making the existence of sugar be suspected, when there is not a particle in the urine.

#### ON THE EMPLOYMENT OF GUTTA PERCHA IN LUXATIONS OF THE CLAVICLE AND FRACTURES OF THE PATELLA.

By M. LESUEUR.

M. LESUEUR having had under treatment a case of luxation of the sternal end of the clavicle forwards, endeavoured to keep it in its place by means of a Desault's bandage applied over a thick cushion, but the displacement quickly recurred. The idea occurred to him to make use of an application of gutta percha of considerable thickness, which moulding itself on the superior part of the chest and shoulders, would, when solidified, afford a most efficient apparatus to keep the parts *in situ*. This expedient succeeded admirably. The softened gutta percha applied to the skin, adhered to it at once. This adhesive property proved of further service. Having moulded his plate of gutta percha on the parts mentioned, M. Lesueur reapplied the Desault's bandage; the turns of the bandage adhering to

the gutta percha, acquired a remarkable degree of firmness, which completed the consolidation of the apparatus, so that during the period of its application not a single turn of the bandage became disturbed. The patient for the first day was kept as immovable as possible, so as to make sure of the consolidation of the mould in the same form as it had been applied in. On the twentieth day, the apparatus was removed; the head of the clavicle had reassumed its normal position, which it afterwards preserved. M. Lesueur also made use of gutta percha in the treatment of transverse fractures of the patella. Two plates of this substance, of a crescentic shape, are applied, one to the superior edge of the superior fragment, and the other to the inferior border of the inferior fragment. He then brought them together by means of straps, directed obliquely across, and attached to the edges of a wooden box-splint adapted to the limb. The advantages of this simple addition to Boyer's apparatus, were followed by the most favourable results in the hands of M. Lesueur in two cases of fractured patella.—*Gaz. Méd. de Paris*.

#### ON PROPHYLACTIC AND CURATIVE SYPHILIZATION.

By VICTOR DE MERIC, M.R.C.S.

OUR age is fertile in inventions and discoveries, which have caused alterations of vast magnitude, and undoubted improvements in the social state of man. The human mind, in its indefatigable activity, has been at work in all the provinces of science and art, and practical applications have followed very closely upon ingenious theories and well-ascertained principles. The science and art of medicine has not escaped the mighty influence of this mental restlessness, and innovations of various kinds have been made for the last half-century. Among these, some, which I need not detail here, have been universally hailed and adopted; and others, into the consideration of which it is not my purpose to enter, have been accepted by a small fraction only of medical men, and rejected by the rest. Now, I consider that new doctrines in medicine should never be set aside without due and dispassionate examination: let them after the scrutiny of close analysis and logical discussion, if they have stood the trial, be adopted; and if found wanting, energetically rejected and condemned. Without enumerating the follies of the day, I would state that the dispassionate examination which I have just mentioned has been ably made, as regards homœopathy, by Dr. Routh; and it is a scrutiny of the same kind, respecting prophylactic and curative syphilization, which I shall now attempt.

The subject is one of a startling kind, and has very probably attracted the attention of many members of the medical profession. Indeed syphilization has been so warmly discussed, and men of such eminence have taken part in the debates, that every practitioner is more or less aware of the insane attempt which has been made to introduce into the legitimate practice of medicine a new mode of preventing and treating syphilis. The supporters of this method propose no less than to saturate every human being with the syphilitic virus, either to cure existing symptoms of the same disease, or to render individuals proof against contagion before any syphilitic manifestations have occurred.

I may perhaps be allowed to state that I take much interest in the question, as I was present last summer at some of the discussions which took place before the Academy of Medicine of Paris, and because I had several conversations with M. Ricord (whose hospital I had gone to revisit) on this unfortunate *isopathy*, as he called it. I need hardly say that this eminent surgeon repudiates with all his might the pseudo-doctrine of syphilization, and no less could have been expected from his excellent judgment and vast experience.

The principal facts bearing upon this question are generally known; but the actual nature of the theory and practice of syphilization, the circumstances which gave rise to the wild scheme, the extent to which it has been

applied, and the arguments brought forward by the supporters of the method and its opponents, are perhaps not very clear to every one. I may therefore serve a good purpose by presenting in a connected form, the features which I have just enumerated, and my own views regarding the new system.

Contagious diseases are conveniently divided into those in which the morbid poison can be isolated and accidentally or artificially implanted upon human beings, and those in which the virulent and contagious principle is known only by its effects, the latter being in general regular, ever alike, and not under our control or guidance. Among the first class, I would mention small-pox, hydrophobia, the deadly effects of the bites of certain snakes, glanders, and syphilis; among the second, I need hardly mention typhus, scarlatina, rubeola, &c. Now, in the former of these two classes, there is but one disease against which an almost certain preservative has been discovered—small-pox has ceased to destroy a large proportion of the infantile and sometimes adult population; and, thanks to the immortal Jenner, the scourge is kept in abeyance. It should, however, not be overlooked that inoculation *preceded* vaccination. No preservatives are known regarding the rest of the diseases of the first class: hydrophobia, the effects of venomous bites (as illustrated by the late accident), glanders and syphilis, remain as fearful and destructive as ever.

But the fact of the inoculation of the small-pox virus having really and truly been ascertained to act as a preservative of the malady, has naturally led to the inquiry whether a similar proceeding might not be equally advantageous in some of the contagious diseases just alluded to; and prophylactic means, especially as to syphilis, were anxiously sought for. By a little false reasoning, it has lately been inferred, that by inoculating the syphilitic virus in sufficient quantity, a man, already affected, might be cured and shielded from further attacks; and others who had never had the disease be brought so far as to be able to expose themselves to infection without being contaminated. I shall presently inquire which are the real tenets of the originator of this plan, and the facts which he brings forward to support his views; but before doing this, it will be useful to throw a retrospective glance at the attempts which have been made in the same direction; we shall thus be enabled to judge more distinctly of M. Auzias Turenne's merits.

In a book published at Paris in 1815, by Luna Calderon, entitled "Practical Demonstration of Syphilitic Prophylaxis," a great number of experiments are given, which were made in 1812 before a committee at the Venereal Hospital of Paris, tending to prove that the author possessed unfailling means of preserving himself from contamination. These experiments were carried on in a perfectly authentic manner, they were constantly successful, and M. Ricord quotes several of them in his work on "Inoculation." It is unfortunate that Calderon kept his secret to himself; M. Ricord, however, thinks that it probably consisted in the use of some caustic saponaceous substance.

It has, indeed, been found that purulent matter from a chancre, mixed with an alkali or a slightly concentrated acid, and then inoculated, produced no effect; but Calderon allowed pure virulent matter to be inoculated upon his prepuce and various parts of the glans, and always left the hospital before applying any of his preservative, whatever it might be. No means but a complete destruction with the caustic are in our days known for obtaining such results, and the register of the hospital where the experiments were made, shows that no mark of cauterization was ever observed.

Another prophylactic agent was lately proposed, also in Paris, by M. Langlebert, and the discoverer has published the favourable results which he has obtained upon himself after the artificial inoculation of the syphilitic virus. The following is the formula:—Alcohol, ten drachms and a half; striped soft soap, prepared with potash, the same quantity. Dissolve the soap in the alcohol; strain, and add five drachms of the essential oil of lemons.

M. Langlebert mentioned the following experiment:—

He took purulent matter from an indurated chancre, and made an inoculation on the *left* thigh of one of his pupils, who had volunteered his services. On the *right* thigh scarifications were made with a lancet charged with the same matter. Nothing was applied to the *left* thigh, but on the *right* side the preservative was used after five or six minutes. A regular pustule sprung up in due time on the *left* side where nothing had been applied, but on the *right* where the preservative had been tested, a mere thin and dry crust appeared. Further experiments have been made upon two other pupils (who had requested the favour), as well as upon M. Langlebert himself, and success is said to have been complete. M. Ricord has not yet reported to the Academy of Medicine of Paris upon this new prophylactic of syphilis.

I shall not enter into the consideration of the other prophylactic means which have from time to time been proposed; suffice it to say, that up to M. Auzias's time inoculation as a *preservative* had not been thought of, but as a *curative* agent it had been used by Percy. This surgeon employed inoculation principally with the view of modifying a very obstinate case of syphilis, the patient having been pronounced incurable. His attention was first attracted by the following occurrences:—A drummer in the French army had been treated for a considerable period for a deep chancre at the corona glandis, a bubo in the right groin, pains in the limbs, and a general icterus. At last tired out by the uselessness of the treatment, he exposed himself to infection, which gave rise to a great number of verrucae on the corona, a new chancre on the prepuce, and the enlargement of the old one. The bubo and pains in the limbs became likewise worse, and the icterus remained as before. The patient was admitted in this state into the military hospital of Besançon, and was perfectly cured of the old and new symptoms by twenty mercurial frictions.

The second case, which gave Percy the idea of inoculating the virus, runs thus:—"In 1777, a gentleman holding office in the Treasury, underwent the usual treatment for a chancre on the velum palati, two on the penis, and a great many mucous tubercles on the verge of the anus. The mercurial frictions caused the two chancres on the penis to cicatrize, but the one on the velum persisted, and the mucous tubercles, which had been cut and cauterized, had soon afterwards reappeared. Aphonia and singing in the ears were at this time superadded to the former symptoms. The patient now placed himself in the hands of another surgeon, but a treatment of six months left him as bad or worse than before. He now fell into loose habits, and became infected afresh; all the chancres took on renewed ulceration; a third one, as well as a bubo in the groin, appeared besides, and deep sores on the whole of the velum became apparent. Percy now undertook this patient; sixteen mercurial frictions were made, and all the symptoms vanished without any salivation being induced."

Let us now examine the case in which Percy, remembering the two preceding ones, actually used inoculation of the syphilitic virus as a therapeutic agent.

The patient was an artilleryman, who had been affected with syphilis for a considerable period. When he came under the care of Percy, he had used a great many remedies, and had still upon him a chancre which had destroyed the left tonsil, another occupying two-thirds of the corona glandis, an eczematous eruption on the perinæum, scrotum, and left thigh, purple papule on the forehead, and a general cachectic, leaden hue of the skin. Percy, after having used bichloride of mercury to no purpose, inoculated virulent matter upon this patient's arms; he made three punctures on the right and three on the left side. On the sixth day, pustules, surrounded by an inflammatory areola, began to appear. On the seventh, the arms swelled up, some axillary glands became enlarged, and the symptomatic fever ran high. On the eighth, the pustules had coalesced, broken, and formed one suppurating sore. The throat had in the meanwhile become painful, and the chancres had not increased. On the fourteenth day, the artificial ulcer of the right arm was cicatrized, but that of the

left had become larger, and the pain which had been felt in the chancre and eczematous eruption had disappeared. On the eighteenth day, the patient came round to the same state in which he was before the inoculation, except that the chancres of the tonsil and the corona were larger, and that a deep ulcer was still observable on the left arm. Percy's father now conducted the case, and with sixteen mercurial frictions, the first of which was begun six weeks after the inoculation, a perfect cure was obtained.

Now what can be inferred from these facts? Simply that old symptoms have, in a few isolated cases, given way, along with more recent ones (the latter being accidentally or artificially superadded), under the influence of the renewed use of the same therapeutic agents which had before failed. But this circumstance does not prove that the fresh symptoms had any direct action on the disease or assisted in the cure. It would therefore be wrong, upon such slight grounds as these, to advise a new infection, the effect of which may, as far as we know, be excessively prejudicial instead of conferring any benefit.

It has, nevertheless, been coolly proposed to inoculate virulent matter again and again, in order to cure both primary and secondary symptoms, and moreover to shield individuals who have never had syphilis from the effects of a casual infection. But when we inquire more closely into the wild theories which have of late been broached, we find that there are four different systems of inoculation, or isopathy, now before the profession. The first—the author of which is M. Diday of Lyons, advocates a kind of vaccination; the second, which belongs to M. Laval, a young practitioner of Paris, restricts itself to the cure of *secondary* symptoms by inoculation; the third, proposed by M. Auzias Turenne, is the so-called prophylactic and curative syphilization; and the fourth, brought forward by M. Sperino of Turin, has much similarity with the third, differing principally in the manner of making the inoculations. It should likewise be mentioned that M. Thiry of Brussels has tried inoculations of the matter of chancre to cure *cancer*. This attempt has not been constructed into a regular system; it does not, therefore, come under the four heads just mentioned. This practice will presently be alluded to. I shall now rapidly pass these methods of treatment in review.

The first system, that of M. Diday of Lyons, is very far from calling for the complete repudiation which syphilization, properly so termed, fully deserves. M. Diday was a pupil of M. Ricord, and has upheld his master's doctrines with great talent at the Venereal Hospital of Lyons, of which he has been surgeon. Like all those practitioners who frequently come in contact with syphilitic patients, he was struck and grieved at the rapid manner in which the disease spreads, and bethought himself, since the most highly recommended prophylactics are of little avail, whether syphilis might not have its cow-pox as well as variola. It was not, however, among the inferior animals that he sought for his preservative, but he fancied that the syphilitic virus, very much weakened, as it is supposed to exist in the blood of patients affected with *tertiary* syphilis, might, by being inoculated upon individuals labouring under chancre, preserve them from secondary symptoms.

It will be at once perceived that this is not a complete imitation of vaccination; for the tertiary blood is intended to preserve from secondary syphilis those persons who are already affected with primary symptoms. M. Diday, however, cherishes the idea of finding a vaccine virus, which may as effectually preserve healthy individuals from syphilis, though exposed to infection, as cow-pox matter preserves from variolous attacks.

This curative vaccination, as it is called, has been the subject of experiments at the Venereal Hospital of Lyons. Sixteen patients, having recent chancres, were subjected to this vaccination, and inoculated, by means of a lancet, with blood taken from a patient suffering from tertiary syphilis. The punctures healed very rapidly, and there was, contrary to what takes place in real vaccination, no local manifestation. No mercury was given, and these patients were watched, after the healing of the chancres,

for six months or more. One of the patients had had an indurated chancre, and was of course attacked with secondary symptoms; a second proved untrue in his statements; and because the fourteen others did not suffer from secondary syphilis after from six months to a year had elapsed, M. Diday jumps at the conclusion that the tertiary blood has acted as a preservative, regardless of the very first tenets of his master, M. Ricord, who says, that simple unindurated chancres require no mercury, because they are never followed by secondary symptoms. So enthusiastic, however, was M. Diday, that he was proposing to take the utmost care of a few patients labouring under tertiary syphilis, and preserve them as storehouses of syphilitic vaccine matter, if the latter could not be kept like the real cow-pox virus.

I am not prepared to throw ridicule on M. Diday's experiments; his intentions are evidently good; he is anxious that syphilis should have its preservative as well as variola; but one circumstance should ever be borne in mind—viz., that small-pox may reign *epidemically* or be *accidentally* caught, but that matters are quite different as far as syphilis is concerned. M. Diday has proceeded very cautiously, and for fear of doing harm, took blood and not pus, and made use of tertiary affections rather than venture with secondary symptoms. His is a harmless error, and forms a very advantageous contrast with the wholesale inoculations of virulent matter to which I shall presently allude.

After M. Diday, we find M. Laval, not exactly in a chronological order, but being second as far as regards prudence and caution in the experiments. This young surgeon took curative syphilization as the subject of his thesis, after having, like a true enthusiast, made experiments upon himself. His view is to substitute inoculations of virulent pus for the use of mercury in the cure of *secondary* syphilis. His ideas were made public after the prophylactic and curative syphilization of M. Auzias Turenne had been proposed and carried into practice, but I mention M. Laval now, because he confines himself to the treatment of *secondary* syphilis.

Experiments were carried on at the military hospital of Val de Grâce, under the patronage of one of the surgeons of the institution, M. Marchal (de Calvi), who took up the subject very warmly. The number of patients was sixteen; seven had syphilitic psoriasis and roseola; four were affected with specific ecthyma and psoriasis; and five had mucous tubercles; almost every one of them had marked induration left in the part where the chancre had first appeared, and all presented tumefied posterior cervical glands. Only two inoculations of virulent syphilitic matter were made, and in a short time the above symptoms disappeared; the induration of the chancres vanished in twenty days, and the secondary symptoms in about ten. The inoculated chancres took, however, *fifty days* to cicatrize.

Now, these experiments (which were stopped by the military medical authorities) prove literally nothing; for it is well known that cutaneous manifestations and the induration left after chancres will gradually go off under the most simple treatment; but this result has very little to do with the eradication of the syphilitic diathesis, which is in general sought to be effected by the use of mercury. M. Ricord showed me repeatedly in his wards, last summer, that dry lint and simple diet drinks were sufficient to remove secondary symptoms of a mild variety, and he used to point out the patients to me with a view of proving the complete insufficiency of the above-mentioned experiments.

One case, however, has been held up as capable of supporting M. Laval's doctrines—viz., that of an infantry officer, who had a spreading secondary ulcer of the tongue. After one inoculation of matter taken from a chancre, the ulcer, which had before been very obstinate, began to improve. Several inoculations were afterwards made; the ulcer went on healing, but the patient was obliged some months afterwards to apply to M. Ricord for *well-marked tertiary symptoms*; so that the case upon which the greatest reliance was placed crumbles into nothing. M. Laval considered himself completely syphilized, and proof against any inoculation, and this circumstance was very much cried

up; but it happened that the purulent matter, which was used to try his powers of resistance, also failed upon other patients. When, however, purulent matter taken from a chancre at the period of development was employed, he was found to be but a weak inoculable mortal after all.

So much for M. Laval and his inoculations proposed for the cure of secondary symptoms! I now come to M. Auzias Turenne, the syphilizer *par excellence*. It appears that as long back as 1844, M. Auzias had made numerous and persevering experiments on animals, in order to find out whether Hunter, Ricord, Cullérier, and others, were not mistaken when they affirmed that the lower animals were unsusceptible of taking syphilis. M. Auzias was afforded great facilities by the managers of the Zoological Gardens in Paris; he carried on his experiments with much care, and did really at last succeed in inoculating chancres upon some monkeys. I cannot enter here into the details of these experiments; suffice it to say, that the ulcerations induced upon the monkeys (behind the ear a locality inaccessible to the animal's tongue) were so *bona fide* of a specific kind, that the pus secreted by them being inoculated upon a German physician, M. Robert de Welz, produced both primary and slightly marked secondary manifestations. Now, it is plain that M. Auzias has really and truly succeeded in giving chancres to monkeys, but I am much inclined to side with M. Ricord in considering this as a mere transplantation; for it should be noticed that the syphilitic disease is more comprehensive than the mere production of a chancre; it is a constitutional affection, and it still remains doubtful whether the lower animals are obnoxious to the malady, as *no secondary symptoms* have ever been observed among them.

Now, during these inoculations upon animals, which proved that it is extremely difficult to communicate the disease to the poor creatures, M. Auzias *thought* that the more numerous the ulcerations were becoming the feebler the later ones developed themselves; and this descending scale seemed to him so marked, that he at last fancied that the animals had become proof against any further infection, and he then looked upon them as being *syphilized*. The fact being thus construed into a kind of saturation, M. Auzias bethought himself that perhaps the same saturation might be effected in man; and in the experiments which he now begun upon human beings, he relied both upon the kind of immunity observed upon animals, and another fact which had been observed and made public by M. de Castelnau, the editor of the *Gazette des Hôpitaux*. This was no less than a species of saturation, or immunity, which the latter surgeon had observed among the prostitutes under treatment at the establishment of St. Lazare, where all diseased women of that description are obliged to repair. M. de Castelnau had noticed that such of these unfortunate women who had frequently suffered from syphilis, had at last become refractory to infection, and were even sought after on that account.

Now, upon these facts, which are, to say the least of them, anything but established, and vaguely and unsatisfactorily described, M. Auzias boldly begun to inoculate purulent matter from chancres upon healthy and diseased subjects, with results which I shall presently describe. Before doing so, however, I must be allowed to refute an assertion which has been made by some of M. Auzias's supporters. They say that Hunter and Ricord made inoculations on a large scale, and that the new doctrine is merely an offset of Hunter's school. Nothing, however, can be more erroneous, for every one knows that inoculations were made both by the English and French surgeons upon persons already affected with syphilis, and with the purulent matter secreted by their own sores. Patients could, in this way, not be any worse off from the experiments which were instituted; and comparing the odious method of implanting syphilis upon perfectly healthy or slightly-affected individuals with the scientific and prudent inoculations of Hunter and Ricord is perfectly unjustifiable.

Now, it would appear that in this instance, as in all circumstances when anything of a strange, new, mysterious, and startling kind is proposed, the human race has been

true to tradition, and numerous victims are being voluntarily made at the shrine of syphilization. So extensively multiplied have inoculations become, both on healthy and diseased subjects, that M. Auzias asserts having tried his method upon more than 300 patients, seventeen of whom are, according to his statement, completely syphilized, and unsusceptible of taking either gonorrhœa or chancre. These are, however, mere assertions, and no cases or facts have been brought before the profession, except such as are of so melancholy and mischievous a description as to attach the greatest blame on the operators.

M. Auzias was nevertheless so emboldened by his pseudo-success, that he applied to the Chief Commissioner of Police for permission to carry on his experiments at the hospital for prostitutes. The head of the police asked the Academy of Medicine to appoint a committee to report upon the doctrine of syphilization, and to advise him how to act: this report has not yet been published. The Academy has, however, largely discussed the matter, in consequence of a report of M. Bégin, which was rendered necessary by M. Ricord presenting before the Academy a patient *supposed* to be syphilized.—*Lancet*.

### IODIDE OF SODIUM.

DR. DAVERI, Chief Physician of the Hospital of Saint Orsola in Bologna, has employed the iodide of sodium instead of the corresponding salt of potassium. The iodide of sodium employed by Dr. Daveri, was prepared by placing three ounces of filings of iron in two and a half pounds of distilled water, and gradually adding, with constant agitation, a pound of iodine; as soon as the mixture had acquired a greenish colour, it was filtered and quickly treated with a solution of carbonate of soda, until all the iron was thrown down. The carbonate of iron thus formed was separated by filtration, the filtered fluid evaporated to dryness, and the residuum again dissolved, filtered, and evaporated, until a pellicle had formed. By this method, fourteen ounces of iodide of sodium were procured in the form of white rhomboidal prisms, deliquescent, and having a saltish taste, less disagreeable than that of iodide of potassium.

The iodide made from iodine and caustic soda is disagreeable to the taste, gives rise to a burning sensation in the fauces, to weight and uneasiness in the stomach, and to gastro-enteric pains.

The dose administered at the commencement of the treatment, was always a scruple of the iodide dissolved in three ounces of distilled water, and given in three equal portions in the course of twenty-four hours. The salt was likewise employed, in the form of ointment, in the proportion of half a drachm or a drachm to the ounce of lard. In the administration of the iodide of sodium, the same rules and precautions are to be observed as apply to the use of the potassium salt. The author divides the 116 cases, on the observation and treatment of which his paper is based, into the three following classes:—1. Cases of constitutional syphilis, in which so-called secondary and tertiary phenomena co-existed. 2. Cases of so-called tertiary lues, in which the use of mercury preceded the treatment by iodide of sodium. 3. Cases of so-called tertiary lues, in which iodide of sodium alone was employed.

Of the first class, twelve cases, in which the symptoms were pains in the bones or periostitis, united with some manifestly constitutional affection of the skin, generally of a papular or pustular form, were treated with iodide of sodium. In eight of these cases the use of the salt alone effected a cure; in the remaining four, it was necessary to have recourse to mercurial frictions, to remove the cutaneous affection which remained after the tertiary symptom had yielded to the iodide. The minimum quantity which succeeded in curing the disease was three drachms, the maximum three ounces; the quantity which was usually required ranged from two to three ounces. The shortest time in which the symptoms were removed was nine days; the longest three months; the average was about a month.

The cases of the second class, or those of so-called ter-

tiary lues, in which the use of mercury preceded the treatment by iodide of sodium, were seventeen. In some of these, six or seven ounces of stronger mercurial ointment had been rubbed in; the average quantity was from four to five ounces. The minimum quantity of iodide of sodium administered was three drachms; the maximum four and a half ounces; the average, from one to two ounces. Those patients who had derived no benefit from a protracted course of mercurial treatment, were cured after the administration of a small quantity of iodide of sodium; while this remedy had to be given to the extent of four and a half ounces, in cases in which only a limited number of mercurial frictions had been used. The patients who resisted the long-continued employment of the ointment, laboured under osteocopic pains, which subsequently gave way to a small quantity of the iodide; while those who practised, without benefit, a moderate number of mercurial frictions, suffered either from syphilitic rheumatism, or from a mixture of syphilis and scrofula. This fact of the iodide being required in the inverse ratio of the amount of mercury previously employed, arises, the author thinks, from this,—that in the first case the use of mercury had, in a great measure, overcome the syphilitic element, which was then entirely removed by the administration of the iodide; while in the second the elimination of the constitutional venereal principle, commenced by the mercury, was for the most part, reserved for the iodide of sodium.

The cases belonging to the third class, comprising those of so-called tertiary lues, in which the iodide of sodium was the only medicine administered, were eighty-five in number; of these, thirty-seven were cases of ostalgia, in the treatment of which vapour baths and iodide of sodium were employed: the minimum quantity of the latter given was from one to seven drachms; the maximum from eight to twelve ounces; the average from two to four ounces. Of rheumatism, the cases were seventeen, likewise treated with vapour baths and the iodide; the minimum dose of the latter being from two to four drachms; the maximum, nine ounces; the average two to four ounces. Of arthralgia, nine cases were similarly treated; the minimum quantity employed having been seven drachms; the maximum two ounces. Of the other varieties of tertiary disease, the numbers were too limited to require special mention, or to justify the deduction of conclusions from them.

Derangement of the stomach, iodic eructations, ptyalism, and affections of the throat, were seldom met with from the time the iodide of sodium was substituted for the potassium salt; consequently, the remedy could be more steadily persevered with and its dose more rapidly increased: circumstances directly promoting the cure of the diseases for which it was administered. In the few cases in which ptyalism occurred, it totally ceased on suspending the medicine for two or three days. In but a single case, did it appear to be obstinate; and in this instance the mouth was, on examination, found to be pale, free from swelling, and very slightly painful. As the patient lay in a ward with many syphilitic patients under mercurial treatment, it was thought the salivation might be owing to mercurial vapour present in the atmosphere—a suspicion which was verified by the result; for on removing the patient to another apartment, free from mercurial contamination, the salivation entirely ceased in two days.

The time required for the cure of nineteen patients treated with the iodide of sodium, was about twenty-eight or twenty-nine days; while with the potassium salt, likewise exhibited in nineteen cases, the average time was, from thirty-four to thirty-five days. Many cases, which had either not got entirely well, or were proceeding but slowly, under the use of the iodide of potassium, were rapidly cured by the substitution of the corresponding salt of sodium.

Several of the cases, however, treated with iodide of sodium, relapsed, and the disease again yielded sometimes to a repetition of the remedy; sometimes to the use of mercurial frictions. But this circumstance cannot be urged against the iodide of sodium alone, for the same is equally

true of every other anti-venereal remedy,—one of the leading features of lues being its tendency to present periods of lull and of relapse, whatever be the therapeutic means employed. The author concludes his paper with the following *resumé* :—

1. Soda being a very common ingredient in our organism, the iodide of its base appears best suited to the human system.
2. The taste of the iodide of sodium is much less disagreeable than that of the iodide of potassium.
3. It is less likely to occasion iodism.
4. It is better borne than the potassium salt, and in consequence of this, its dose can be almost daily increased; and it thus becomes a more efficient remedy.
5. It has sometimes succeeded where the iodide of potassium had failed.
6. We may commence by giving daily, in three equal doses, a scruple of the salt dissolved in three ounces of distilled water, increasing the strength of the solution, every two or three days, by six grains. Some patients have, in this way, been able to take more than two drachms a day, without suffering the slightest inconvenience.
7. The iodide of sodium is admirably adapted to cases in which the corresponding salt of potassium is indicated.
8. The iodide of sodium is the best substitute for mercury.—*Chemist and Association Jr.*

#### ON THE SYMPTOMATIC VALUE OF CEREBRAL SYMPTOMS IN INFANTILE FEVER.

By Dr. MEREI.

THE practitioner is frequently harassed by anxious doubts as to the character of headache and other cerebral symptoms in infantile fever; and as a correct diagnosis is of the last importance under these circumstances, we extract the following practical remarks from the valuable course of lectures to which we have previously been indebted:—Headache, a most constant companion of fever, easily appreciated and less alarming in adults, appears more obscure and threatening in children, because they cannot give us symptoms by words, so as to facilitate the distinction from congestion or meningitis. It manifests itself in the child in different degrees, when lifted up in the arms of the mother or nurse, by its difficulty or inability of holding its head upright, by leaning it on the shoulders, along with simultaneous appearance of some perpendicular wrinkles on the forehead between the brows, languor of the eyes, falling of the upper eyelid, and plaintive moaning; considerable degree of heat on the front. The little patient keeps the head rather steadily and quietly in the same posture, without restlessly moving it; and all the above symptoms are equable for some time. Recollect what adults say in this state by words, and thus you will have the whole more clearly before you. Sometimes they complain of acute, at other times of dull pain, on pressure, or giddiness. These differences it would be difficult to trace in a child; we must content ourselves with knowing that there is headache present, and judge of its importance according to the degree and weight of the above symptoms, comparatively with the general state, or some important local affection. In a little child we must be very careful, because painful abdominal affections may cause dropping of the head, moaning, and frontal wrinkles, just as if the head itself were suffering pain.

As to the nature of febrile headache, it is but an old superficiality, which always identifies pain and heat in the head with congestion. We know little of the nervous fluid yet, so plentifully developed in the brain, and of the laws of its circulation. The fact, however, stands firm, that paroxysms of intermittent fever present, as to heat and pain, a severe kind of headache, and still there is little fear of meningitis. Nervous headache in delicate ladies manifests the same severity, with the same exclusion of meningitis. In both cases, generally, leeching does not cause relief. Thus we may be allowed to establish a febrile headache of the nervous kind, perhaps a congestion of the nervous fluid causing pain or spasm. As to congestion of blood in the brain, which of course may also be connected with febrile headache, just as it complicates, occasionally, even hysterical headache—this, in the height of fever, I

do not know how to distinguish exactly; I believe, however, that in the case where congestion is the principal affection, there will be the appearance of a higher degree of heaviness of the head, and of the languor of the eyes and eyelids, more oppressive somnolence, or even soporose sleep, high heat on the forehead, but less of the extremities, and less moaning. And in the case of decided inflammatory action in the envelopes—that is, in the first stage of meningitis, there will be, with a given degree of heaviness and heat, less sleepiness, and, instead of steady posture, even restless rolling and pushing of the head here and there, and a more lively expression of pain, with occasional startings and screamings. The second stage is too clearly characterized to admit mistakes.

As to eclampsy, during the stage of febrile heat, I have been satisfied, by many dissections, that it is less frequently a symptom of the first stage of meningitis than the effect of different febrile and non-febrile, gastric, or other disturbances acting upon the nervous system, consequently there is a more natural combination between eclampsy and headache of a nervous or spasmodic kind, than between eclampsy and meningitis. Gastric disorder, during fever, I believe, frequently may be the simultaneous effect with headache, and is, perhaps, too generally considered as its source; at any rate, whenever fever, and along with the signs of headache, gastric disorder is well ascertained by its local and functional symptoms, we may be almost sure of the non-inflammatory nature of that headache. Tense epigastrium, for example, and furred tongue, are frequently connected with nervous, but never, I believe, with inflammatory headache. Moreover, consider the following comparative analysis:—A paroxysm of fever, with headache, in order to make us apprehend acute primary congestion, or meningitis, must be rather intense. Now, if this be the case, the temperature of the skin in fever will be high, and so all over the body, the highest on the epigastrium; and the pulse of a little child, between 150 and 170, or more. And all these conditions unitedly, will be the more expressed in high gastric fever, in which also the highest degrees of sympathetic headache do occur; whilst in the case of active congestion or meningitis, generally, and proportionally to other symptoms, there is less heat and dryness. Hands and feet frequently even cool, in comparison with the forehead, and in many cases the pulse less frequent.

Vomiting of bilious liquid may be the effect of simple fever or febrile headache, as well as of meningitis, and in both cases the epigastrium is soft, consequently this symptom has in itself not much diagnostic value.

Acute hydrocephalus (anatomically different from genuine meningitis), in the great majority, does not set in so suddenly, and under that sudden appearance of high fever, as we have described it above; a careful observer will, therefore, be less exposed to confound the first stage of hydrocephalus with the simple febrile head-symptoms, than the first stage of meningitis.

In conclusion, I have been satisfied, too, that simple febrile headache is far more frequent than meningitis or hydrocephalus.

All these different diagnostic points, of course, taken *singulatim*, admit of exceptions, and cannot be trusted by themselves. Considered, however, in relation with each other, and many special circumstances of the case, they are of some value. I nearly forgot, to recommend great care and application in accustoming your hands to distinguish the proportion between the heat on the forehead and on the epigastrium. This, I find, is important. In congestion or meningitis, the heat of the epigastrium is less. In medical practice there are few points of greater difficulty than that in question. Even in adults we labour sometimes under the ambiguity between the nervous and congestive character of headache. Nor can it be denied, that in many instances congestion may join spasmodic pains; or that headache, which at first was but an effect of nervous disorder, proper to fever, may become congestive. The question will be—shall you in a given case of recently developed primary fever, under the mentioned appearance

of the head, resort to energetic leeching, or wait, or adopt some milder means? By the industrious and clever application of your senses and mental powers, an increasing number of patients will increase your discernment, which I only wish to assist by giving you some facilitating directions. There are, however, those intermediate and undecided cases in which we cannot get rid of the ambiguity between simple headache and congestion or meningitis. This has been the case frequently with me, though I have seen thousands of them; and it will be the same with you. In similar emergencies, I can but recommend you the following conduct:—Consider well the constitution of the child. Is it strong? Then, after you have freely moved the bowels, and energetically used cold fomentations without effect, leech it; in the contrary case, wait a little longer before you take blood. And, in spite of the apparent vehemence of head-symptoms, abstain from taking blood if you have before you one of those scrofulous habits with thin legs and a large, flat, angular skull, or a rachitic or a very delicate decidedly nervous child. These are all exceedingly liable to febrile disorder and headache, but not to inflammation, and are injured by loss of blood.

Cold fomentations on the head, abundant cold water and sugar to drink, and perhaps a cooling injection (of thin barley decoction, with sugar and oil), will best answer the indications of that hot stage, with headache, within the first twenty-four hours. Sinapisms are improper at that stage for tender infants; they might increase the fever by irritating their tender skin. If, then, the general febrile symptoms continue longer than twenty-four hours, with unabated heat, pulse, and thirst, and heaviness of the head persists, or increases, together with languor of the eyes, and heavy moaning, restlessness, and painful crying, or occasional outcries, where no remarkable gastric derangement is discoverable by the above-mentioned signs, and after the bowels have been moved, then the indication of leeching acquires more weight and consideration.

Your call in these cases ought to be repeated after a few hours, and again the examination be performed with the same minute care as before. Do not forget to particularly investigate mouth and throat, outside and inside, and offer the child some water and sugar to drink, carefully observing his swallowing movements; and if you see they are not free, as if checked under expression of pain—in one word, if you find the slightest signs of pharyngeal irritation, with a degree of dryness in the mouth, do not hesitate to order an emetic. This is one of the important points of children's practice. In hundreds of similar instances, I have ordered the emetic where I should not have felt pressed to order it to grown up people; the reason is, the greater frequency, rapidity, and danger of laryngeal and pharyngeal inflammations of children.—*Ranking's Abstract.*

#### REVIEWS AND NOTICES OF BOOKS.

A TREATISE ON OPERATIVE OPHTHALMIC SURGERY. By H. HAYNES WALTON, F.R.C.S., Surgeon to the Central London Ophthalmic Hospital, and Assistant-Surgeon to St. Mary's Hospital. 8vo. pp. 628. London. 1852.

It is some time since we had the pleasure of perusing an off-hand, manly book or paper on Eye Surgery; and some time, too, since we met one conspicuous for its honesty. The ophthalmological literature of London especially, has been for some time more remarkable for its diminutive than its large character, more for its caution than its candour. This being so, the book before us proves an agreeable novelty, for it is evidently written by a man having confidence in his resources, and who feels that he can afford to show fair play even to rivals. It is also somewhat novel in its aspect, in consequence of the evidence it contains that the author is a Surgeon; for with reverence be it spoken, our craft seem to pride themselves upon their alienation from that calling. The author does not profess to be the maker of a great book to supersede all other books, but

rather to provide the practitioner with one which will teach him as much as he himself knows, or perhaps as much as he thinks it necessary for him to know. Neither does he profess to give the result of his own experience exclusively, although he gives enough to prove that he has some of that essential qualification. The work, in fact, is a fair intelligible account of the operations required in Eye Surgery, with no small amount of illustrative comment on the diseases which render them necessary and the treatment which contributes to their success. It is divided into twenty-two chapters, treating the subject as follows:—

“History of Ophthalmic Surgery—The use of Chloroform in Ophthalmic Surgery—Ophthalmic Instruments in general—Injuries from Mechanical and Chemical Agents, Burns and Scalds, Echemosis, Blows, Wounds, Chemical Injuries—Foreign Bodies on the Surface of the Eye—Larvæ of Insects under the Lids—Foreign Bodies within the Eyeball—Ossification of the Ocular Tissues—Affections of the Eyelids—Diseases of the Lachrymal Passages—Abscess of Lid—Complete or partial Adhesion of the Eyelids to the Eyeball—Adhesion of the edges of the Eyelids—Encroachment of the Skin on the corner of the Eye—Falling of the Upper Eyelid—Trichiasis—Entropion—Entropion with Trichiasis—Ectropion—Obstruction of the Meibomian Ducts—Conjunctival Calculi—Affections of the Puncta, the Canaliculi, and the Lachrymal Tube—Caries of the Orbit—Nævi Materni—Dilated and Tortuous Veins—Aneurism by Anastomosis—Incision of the Conjunctiva, and of the subjacent Cellular Tissue in Chemosis from Purulent Ophthalmia—Strabismus or Squint—Internal Squint—External Squint—Tumours of the Eyelid—Tumours of the Conjunctiva—Tumours involving the Cornea and the Sclerotica—Tumours of the Orbit—Enlargement of the Lachrymal Gland—Tumours connected with the Lachrymal Gland—Protrusion of the Eyeball—Protrusion from causes within the Orbit—Protrusion from Anæmia—Rheumatic Inflammation of the Ocular Sheath—Abscess and Inflammation within the Orbit—Periostitis of the Orbit, and Disease of the Optic Nerve—Staphyloma of the Sclerotica and of the Cornea—General Enlargement of the Eyeball with Disorganization—Conical Cornea—Removal of Opacities of the Cornea by Operation—Transplantation of the Cornea—Cataract—Varieties of Cataract—Cause of Cataract—Nature of Lenticular Cataract—Hard Cataract—Soft Cataract—Capsular Cataract—Distinctions between Cataract and Amaurosis—Cataract and Glaucoma—Operations for Cataract—Preparation of Patient—Operation for Extraction—Operation for Displacement—Operation for Solution—Operation for Capsular Cataract—Operation for Drilling—Spectacles necessary after loss of Crystalline Lens—Entozoa within the Eyeball, and about the Ocular Appendages—Cysts within the Chambers of the Eyeball—Artificial Eyes—Malignant Affections of the Eye—General Considerations, including Definition of Cancer; Microscopic Character of Cancer; Origin and Physiology of Cancer in connexion with Treatment; Question of liability of the Eye to Cancer—Encephaloid Cancer of the Eyeball—Melanosis—Scirrhus—Cancer of the Orbit—Cancer of the Eyelids—Cancer of the Lachrymal Gland—Question of the propriety of Operating in the several Varieties of Cancer about the Eye—Artificial Pupil—Conditions under which an Operation may be undertaken, and those which contraindicate it—Relative advantages of the several positions in the Iris for a Pupil—Size of the Pupil—Shape of the Pupil—Classification of the principal Morbid States of the Eye requiring a Pupil, with the most appropriate Operations—Concluding General Remarks—Exstirpation of the Eyeball—Removal of the entire Contents of the Orbit—Removal of the Eyeball alone.”

The text is illustrated by 169 engravings on wood by Bagg, which, although uncoloured, present much better representations than the florid pictures usually provided by copper-plate artists. Here is the chapter “On Ophthalmic Instruments in General,” by way of specimen of the author's method:—

“It is easy to comprehend the extent of influence exerted over the success of a surgical operation by the perfection or imperfection of the instrument with which it is performed. It may even happen that the defects of the instrument shall amount to a prohibition of obtaining by means of it, the effects which it is intended to accomplish; and if this be the

case in surgery at large, it is more particularly true in ophthalmic operations. To lessen the defects of an instrument, is tantamount to an improvement in the branch of surgery to which it belongs. Simplicity and due adaptation to the purpose intended, are the qualities which a surgeon who operates on the eye should endeavour to acquire for his implements. The improvement of those in our day, contrast advantageously with the coarseness of form, and inferiority of workmanship, in times past. For these reasons alone, I should deem it proper to dwell somewhat on the subject of instruments; but further, I take this view of the matter, that in treating of any department of operative surgery, a great opportunity of communicating practical instruction is lost, when hints and observations on the instruments concerned are omitted. The plan proposed is, to introduce the several instruments with the subjects requiring their use, and to describe them apart from the operations, as it possesses the advantage of allowing a fuller attention for them than if they were spoken of digressively; while the subsequent details of the operations themselves, being uninterrupted, will then most readily command the attention of the reader. Some few, of general use, will be given at the end of this chapter. As each instrument will be illustrated by an engraving which will convey the most exact ideas of it; little more than those points only which deserve especial attention will be dwelt on in the description, or which the figure less prominently sets forth. The instruments that are introduced are those I am actually in the habit of using, and which appear to me to be the most appropriate to each occasion, and the most convenient for the several purposes which they are intended to fulfil. With ophthalmic instruments, lightness is an element of the highest importance. The lighter they are, the greater is the delicacy with which they can be applied. With light instruments, the resistance to be overcome is better appreciated, as well as the amount of the force required for that purpose. The blades should not be of greater size than the use intended requires; but in a far greater degree the same property is attained by exchanging the ivory handle so generally adopted, notwithstanding the nicer appearance, for one of light wood. In all other respects the minimum of the dimensions compatible with the kind of instrument, should be made the rule. In successive years, as I have required to renew my instruments, I have gradually had their size reduced; and the effect has been to adapt them better to the several operations. Besides remedying the clumsiness and awkwardness which attach to those of greater bulk, in several instances positive evils arising from inordinate size have been avoided.

To all small instruments, such as cataract knives, cataract needles, and the like, I prefer round handles, for when of this form they can be held with more ease and freedom, while stiffness and constraint are overcome, and a more individual independent control is thus given to the fingers. I am also of opinion that the handles of such should be smooth, and not cross-cut. There can be no other reason why the handle of a surgical instrument should be roughened, and thereby rendered unpleasant to the touch, as well as less suitable for delicate use, than that surgeons, having been careless about the subject, have permitted the instrument-maker to indulge his fancy, merely to give an air of finish to his workmanship. I believe it to be true, and if so, it is a fact of much significance, that there is no other manual art in which rough-handled instruments are used. All instruments designed to puncture the cornea, should have such a form, from the gradual increase of thickness from the point, as to act on the principle of a stopper in the aperture that is made; the effect of which is to retain the aqueous humour as long as possible, so that the natural prominence of the cornea is for a time preserved, the danger of prolapse of the iris is obviated, and the subsequent steps of the operation are facilitated. The gradual augmentation of size sufficient for this purpose, while a proper stiffness of point is preserved, need not, in needles, exceed at the largest part from 1-36th to 1-40th of an inch. Sharpness of point, and keenness of edge, are here of paramount importance; and these qualities of a perfect instrument should be carefully sought after, and ascertained by delicate processes. To test the point, the best criterion I know is the little drum made of the cuticle stripped from the softest kid skin, and stretched over a metallic cylinder. A less perfect method is, to stretch the cuticle across the fingers. In either case, if the point be in proper order, the mere weight of the instrument should cause it insensibly to penetrate the tissue. If, on the contrary, the point be dull, it requires to be forced through; if otherwise defective, by being turned; and if broken, in addition to the force re-

quired to make it penetrate, a sharp cracking sound is emitted. In consequence of the natural pores in the cuticle, several punctures should be made to ensure the passage of the point of the instrument through an unbroken space. The edge should be tried on some part of the hand where the cuticle is thinnest; for instance, on the ball of the thumb, and I cannot express myself more concisely than by saying, that with a slight drawing motion it should at once enter, or 'bite,' as instrument-makers say. It is necessary, also, that scissors be inspected. Their efficiency depends not only on the blades being properly sharpened, but, besides, on being lightly made and securely riveted. The simplest, and, at the same time, the surest test is, to close the blades gently, and without any lateral pressure, on a very thin piece of wetted paper. If effectual, they will readily divide it; if not, they will close over it without cutting. I cannot refrain from adding a remark on sponges. It is hardly conceivable that the success of an operation can, in any degree, be dependent on the mere purity of a sponge; yet I have the strongest reason to suspect that in many cases the partial or entire failure of the process of adhesion after incisions, has depended on the transmission of particles of sand from the sponges to the edges of wounds. The impossibility of buying a new sponge that is not loaded with earthy particles, is well known. To remove these, time is requisite; washing, necessary as it is, cannot at once cleanse them. The best method of procuring them free of grit is, to employ the best sponges of the shops for common domestic purposes for several months, taking care that on frequent occasions, when dry, they are beaten for some time.

**Scalpel.**—An instrument of such general use, and so well known, would have been passed over in silence, were it not that the kind here advocated is reduced considerably below the size of scalpels in general. The ordinary ones are decidedly too large for all dissecting operations on a small scale, especially such as those on the eyelids, where precision and neatness are imperatively demanded; and those for the removal of tumours about the eye and its appendages, particularly when encroaching upon, or actually lying within the orbit. The point is placed centrally, and this position, while it allows of a requisite amount of curve, renders it better adapted for minute dissection than when it is in a line with the back of the blade; and in a central point there may be the union of the greatest fineness with the greatest strength. In nearly all operations with the scalpel, it is the point of the blade that is principally available, and to its properties the value of the knife is chiefly due. The breadth of the handle is of some consequence, for if carried beyond a certain extent, it is not readily fingered. I also recommend that the parts to which the points of the fingers are applied, should be rounded. The length may be what fancy suggests, unless, as is the case with myself, the instrument be held in a particular manner, as a common table knife is held, my fingers being placed near the blade, a method which demands shortness of handle. This mode of holding it I adopt for almost all purposes, finding that it combines the greatest freedom of motion with the greatest power, and the lightest touch.

**Forceps.**—The proper length is such as allows them to rest on the hand between the thumb and the finger, when held in the ordinary manner. Any length beyond this is useless, and increases their weight. The blades should be slightly bowed, well hardened, and of a substance, in thickness rather than in breadth, that will not allow them to slip on each other, or bend under any force of pressure that can be required during their use; for, were their extremities to gape, which they surely would if the centres of the blades were weak, they must cease to be effectual. The spring should not be made stronger than sufficient to sustain their weight. Round points are, I think, superior to any other form. The holding, or interior surfaces of the extremities, should be raised, and obliquely cut, for at least a quarter of an inch, the serratures being large, and exactly fitting. This roughness is quite compatible with an accuracy of edge adapted for minute purposes. It is frequently required to use tenaculum forceps in operations about the ocular appendages, for the ordinary ones do not lay hold with sufficient firmness. In order to be effectual, their blades should be stout enough to enable sufficient pressure to be made at the points. When shut without an intervening substance, the teeth necessarily cross. A catch-spring, like that usually added to tenaculum forceps, and originally introduced for Amussat's treatment of bleeding arteries by torsion, is not only useless for dissection, but a decided impediment.

**Lid-retractor.**—Of the many instruments in use for the

purpose of retracting the eyelids, whether to procure an examination of the eye, or to facilitate the performance of operations, I give the preference to that which is designed to be inserted under the lid. The bent portion deserves attention. It should not be longer or more obtuse than sufficient to secure and confine the edge of the lid, otherwise its action might be detrimental; because if the sinus or sulcus of the lid were reached, on its introduction, a resistance would be immediately encountered, which would not only prevent the lid from being properly raised, but be a source of pain; owing to the dragging and violence then requisite to effect any degree of retraction.

**Suture Needles.**—That the stitching of wounds is very often the most painful part of an operation, is a fact early impressed upon the student of surgery. Without doubt, much of the suffering is too frequently to be attributed to the imperfection of the needle. Good surgical needles are rarely to be met with, merely because their manufacture is in general neglected, and they are not rendered hard enough to bear proper sharpening. The point, or cutting part, should be large enough to make a channel through which the shaft can glide with ease, or at least pass without force sufficient to stretch or tear the skin. These requisites seem to be fully united in the well-formed gloves' needle, which has three edges. The stoutness should be proportionate to the thread which is required, by which standard the size of a needle should invariably be regulated. The length is a matter of convenience. Where circumstances admit of choice, I always prefer the straight form, because a straight needle enters more readily and is more easily guided, than a curved one. A different body is desirable for a bent needle. The front or concave part should be quite flat from side to side, and the posterior or convex side, oval across. If both are oval, the edges cannot be made thin enough, consistently with smallness and strength.

**Curved Scissors.**—The slight bend in the blades of these scissors renders them very useful on many occasions, and the ophthalmic case is scarcely perfect without them. The points should be of a certain width, and not too delicate, in order to ensure proper strength. Within the last two years, Messrs. Weiss have registered two kinds of joints for scissors, and other double-bladed instruments of the same class. The one is called the lever-joint, the rivet being placed at the side in an angular projection, by which it is said that greater power is given, and the mode of cutting is rather improved, and a substance is less likely to slip from between the blades. The other is a sort of lock-joint, a screw not being used, and the advantage of which is, that the blades do not become loose, as often happens, but ever keep their degree of tightness, and the instrument can be the more readily used with either hand, and easily unlocked for the purpose of being cleaned."

After the observations we have made, our readers will not wonder at our expressing a hearty approval of Mr. Walton's book. Something of the kind was just now wanted, and we rejoice to see the want so well supplied.

**SERRES-FINES IN SUPERFICIAL RUPTURE OF THE PERINEUM.**—Dr. Crisp recently drew attention to a small instrument, called in France the "serre-fine," which he had seen used in Paris eighteen months since for the purpose of uniting the edges of wounds. He thought that these pincers were scarcely known in this country, and he believed that they would be found most effectual in arresting the bleeding from leech-bites, although he was not aware that they had been recommended for that purpose. He had tried them in one instance with immediate success. His chief object, however, in drawing attention to them, was in relation to the treatment of superficial rupture of the perineum. Dr. Deidier of Montpelier, has published, in the *Revue Thérapeutique du Midi*, January 15, 1852, a case of rupture of the perineum during labour, treated successfully by these means, in which the rent extended through the cutaneo-mucous tissue and constrictor vaginae. Three serres-fines were applied immediately after the laceration; the last was removed after forty-eight hours. The thighs were kept together, and the united surfaces carefully washed. On the sixth day the patient had a hard evacuation without dragging the parts, and on the ninth day the wound was perfectly healed. Dr. Crisp thought that this plan of treatment was so simple, and so easy of application, that it was worthy the attention of the profession.

## MEDICAL PRESS.

"SALUS POPULI SUPREMA LEX."

DUBLIN: WEDNESDAY, MARCH 9, 1853.

It is often with some hesitation that we venture to handle a particular topic in that essential compartment of our journal which is devoted to the theme commonly denominated a "Leader," or "Leading Article;" because we often find that what is of high interest to some is of no interest whatever to others. We often, too, experience this hesitation the more, when we recollect the impatience with which one section of our readers view a discussion which another enjoys, sometimes even so much as to elicit remonstrances not very flattering to our editorial sagacity. When we exercise our critical abilities in the analysis of a difficult question of college law, a practical friend in the provinces will be as much disappointed as our metropolitan friend will be when we display our sympathies by a denunciation of some provision in a Medical Charities Act. "What," says our worthy country client, relying on us for his weekly meal of medico-literary provender, "what have we to do with college law or educational imperfections?" And "what," says our consequential patron in town, "have we to do with Poor-law Guardians and Dispensary Doctors?" Nay, others may start up and say, "what have we to do with either of you, gentlemen, or your personal objects; we are engrossed by higher aspirations; we think of scientific pursuits only, and have no relish for your medical politics?" Under such circumstances, what can we do, but mitigate the evil by as equitable a disposal of our pages as we can well make: one topic this week, and another next, until all are discussed. Keeping this consoling compromise in view, we venture on this occasion to revert to a subject often before handled and never to be left at rest. If there be amongst our readers any sick of the discussion of Medical Education, sick they for a time must be, as though they were tossed in any other ugly sea; for to Medical Education we must from time to time return, as surely as we must return to "Medical Charities," "Coroner's Law," or any other subject which interests a large portion of our brethren. But Medical Education can scarcely be considered a topic unworthy of consideration by any man, be his prospects and pursuits what they may. As we have had frequently to urge, it is from vicious educational arrangements that the practitioner has most to fear. Tangible evils, the results of bad laws or bad interpretation of laws, are easily recognized, and by perseverance may be corrected; but evils which elude the grasp or escape detection can scarcely be cured: in fact, they become known by their consequences only, and are not perceived until it is too late to combat them. We must repeat what we have lately had to observe. Of all the dangers to which the practitioner is exposed, that of an inundation of imperfectly educated competitors is the greatest; and this danger he can only avert by using his influence to prevent the practices which may lead to it. If any system prevails in the Schools by means of which candidates for professional employment can be formally accredited without substantial qualifications to practise, that system should be abolished; for it is as ruinous to the junior who avails himself of it as to the senior who deplures its effects. But does any such system prevail? The question is a provoking one, but nevertheless

it must be put and answered, however unpalatable. Without pointing to any locality or to any particular institution; to Dublin, London, or Edinburgh; to Colleges, Universities, or private Schools, we, without fear of contradiction, assert that no disinterested man can deny that at the present moment persons can obtain Medical Degrees and Surgical Diplomas without adequate study or opportunities of instruction. Not only can they obtain such qualifications to practise by prescribed attendances and exercises obviously insufficient, but they can obtain them by evading or neglecting even these, inadequate as they are. We do not mean to deny that this has taken place before to a limited extent, but we do venture to assert, that it has now been reduced to systematic practice, and promises to become the rule and not the exception. Adducing, what we hope is an unusual case, as proof of the imperfection of the arrangements to enforce discipline in the Schools, may best serve to prove that the results to which we allude follow. It cannot, we believe, be denied, that in some cases the "needful" in the shape of "certificates" can be obtained without any residence at the places where the Schools affording them are situated; that, in fact, a person may have his name entered as a student, pay his fee, and take his certificate, without the expense or trouble of a journey from home. This, we admit, is an extreme case, but if such can occur, the possibility of less difficult achievements in the same way may be admitted. In truth, we believe that no one now attempts to conceal the fact, that "the certificates" which are held to be evidence of devotion to study and proofs of proficiency can be obtained without any adequate attendance or exercise. We have heard it asserted by one well qualified to pronounce an opinion on such matters, that not only is this the case, but that a cunning artist will "pass a man" who never entered the wards of an hospital, attended a lecture, opened a book, or took a dissecting knife into his hand; nay, that in certain cases where the party is incorrigibly idle and stupid, experienced operators are obliged to interdict all such methods of acquiring the requisite knowledge, and to insist upon a rigid restriction to the grinding room. This probably is an exaggeration, and some may say it is an extravagant one, but that it has some foundation in truth cannot be denied. Under such circumstances, it is not surprising that the practice of substituting this method of instruction for every other should prevail, and that the policy of depreciating everything else naturally flows from it. It is now notorious that in certain quarters every species of information, not absolutely necessary to meet the present exigencies of the Examination Hall, is "cried down," and every branch of knowledge not immediately required for this purpose is coarsely ridiculed or discarded with opprobrious epithets. The consequences of such proceedings all must foresee and all must deplore, but none more than those already engaged in practice, who must meet as colleagues or encounter as rivals the persons ushered into professional life under such influence.

### PARLIAMENTARY REPRESENTATION OF THE MEDICAL PROFESSION.

As this question begins to assume a more consistent shape and decided tone, we copy the following articles respecting it. We are aware that many prudent men entertain doubts as to the policy of such a movement, or even the policy of accepting the privilege if offered; but as "much may be said on either side," we so far touch the matter:—

Dr. Beek has fully succeeded in making out a strong case for his *Alma Mater*. He has not indeed shown altogether to our

satisfaction that this particular privilege was in the contemplation of those, who advised the granting of a charter to the University of London; or of the legislature, in such acts of parliaments as have since been passed in ratification of it: but he fairly argues, that a parliamentary representation is a legitimate extension of the principle therein recognized; and he proves by statistics, that the University of London has already attained such a degree of development, and reckons so large a number of graduates, as to place it in a position advantageously to exercise the franchise. The same statistics, however, go far to show the correctness of Dr. Paterson's prognostication, that the medical element will not preponderate in this constituency. It appears from Dr. Beck's own showing, that the graduates in arts of the University of London are to those in medicine, nearly as two to one. Unless there should exist among the former, therefore, a much greater diversity of sentiment than is likely to be the case, we cannot see what chance there is for the medical part of the constituency to turn the election in favour of a candidate pledged to make medical questions and interests his especial study: and even though they should succeed in this, we are very sure that the great body of the profession in England will not stand quietly by, and see their concerns committed to the keeping of a favoured few. Dr. Beck appears to think that the claims of other universities, which are still unrepresented in parliament, must be postponed to those of the University of London, because their graduates have no voice in the direction of their affairs: and Mr. Disraeli is quoted, as stating this to be a great obstacle to their obtaining representatives. We cannot see the slightest force in this objection. When a gentleman filling a high official situation suggested, in the House of Commons, that militia-men might be admitted to the exercise of the franchise, it was not thence to be inferred that they were likewise to be privileged to assemble and enact statutes for the government of the regiment, or make grants of money out of the regimental chest. Surely it is very easy to enact that the graduates of a particular university shall have the power of electing members to represent that university in parliament, without conferring upon them other corporate rights or privileges. These may be very desirable in themselves, and for the sake of binding more closely together the academic body; but they are obviously not essential to the proper exercise of the franchise. We have been a good deal surprised to find a gentleman in the position of Dr. Beck, who ought to be well informed on every such point, speaking of the degree of the University of Edinburgh as a mere honorary certificate. This is not correct language to employ of a diploma which entitles its possessor to style himself M.D., which enables him to practise in our most distant possessions, and which constitutes the sole legal qualification of many of our most eminent provincial physicians at home. Whatever privileges, in respect of practice, are enjoyed in England, or elsewhere, by those holding their degrees from the University of London, precisely the same are inherent in the Edinburgh degree, and have been enjoyed, by long prescriptive right, by graduates of that university. In any way to depreciate the one degree, is simply to depreciate the other also; seeing that both enjoy the same legal recognition, and that neither is conferred without satisfactory evidence of the candidate having completed a prescribed course of study at accredited schools of medicine, and a full and rigid examination as to the extent of his medical acquirements. For the reasons now and formerly stated, we still maintain that the representation of the medical profession in parliament is urgently demanded; and that the enfranchisement of the University of London, or of any other university, is an entirely different question.—*Association Medical Journal*.

#### LETTER FROM DR. SNOW BECK.

SIR,—The number of graduates is nearly 800, of whom one-third are graduates in medicine, nearly two-thirds in arts, and about one-sixteenth in laws; whilst their numbers are increasing at the ratio of nearly one hundred annually. The number of under-graduates is about 1500, to which upwards of 200 are annually added. It is therefore urged that the time has now come for giving to this considerable and increasing constituency the privilege and advantage of returning members to parliament, as enjoyed by the other universities, and as guaranteed to them at the foundation of the University of London. It is also evident that the claims of this university rest upon peculiar and especial grounds. As regards the medical graduates: many are physicians, some consulting surgeons, and a large proportion are in general practice. At least one-half hold posts of responsibility in the

London and country hospitals. About one-third of the whole number are settled in London, and a large number in the principal towns of Lancashire and the West Riding of Yorkshire. Now it is contended that a constituency of this kind will fairly represent the feeling of the medical profession in England. And as the members for the University of London will have no local interests to engage their attention, it is considered that the medical graduates, forming more than one-third of their constituency, will have a right to require that they should make themselves fully acquainted with medical questions, and thus represent the interests of the medical profession in parliament more efficiently than has hitherto been the case. Should the present movement succeed, it is more than probable that the members of the University of London will be men of experience, of liberal views, and of high standing in parliament; for the choice is not restricted to the metropolitan graduates, nor, it is hoped, will it be fettered by the qualification of property. With pardonable partiality for his *Alma Mater*, Dr. Paterson says: "There is only one university in the united kingdom, that of Edinburgh, in which its medical graduates would have a preponderating voice in the election of a member of parliament, were one to be conceded to them." As stated by Mr. Disraeli in the House of Commons, in May last, there is, in the constitution of the University of Edinburgh, a great obstacle to their obtaining representatives in parliament. This obstacle is, that the graduates are not members of the university; they have no standing in it; nor have they any voice in the direction of its affairs. The University of Edinburgh consists solely of the professors, who are appointed and controlled by the Town Council; the degree is simply an honorary certificate, which confers no corporate rights or privileges on the possessor. Hence, before the University of Edinburgh would have any claim to be erected into a parliamentary constituency, it would require to be remodelled, and its graduates incorporated as members of the university. And in the meantime, I doubt not that the present support which the movement of the University of London has received from the medical profession, will continue, based on the broad principle, that whatever tends to elevate a part of the profession tends also to elevate the whole body; and also that, through the members of this university, the medical interests will be more fully attended to in parliament than they have yet been.

#### LETTER FROM JAMES BEDINGFIELD, ESQ.

SIR,—It affords me great pleasure to see that you have taken up the question of "Medical Men in Parliament," upon an enlarged and liberal basis. For myself, I am decidedly of opinion that Dame Partington, with her mop, would as effectually check the encroachments of the ocean, as one or two members, returned by the London University, would put a stop to, or correct the existing abuses in our profession.

In the year 1834, in an address delivered in the Town Hall, Ipswich, I expressed an opinion, that until we were fully and fairly represented in parliament, we should endeavour in vain to effect any substantial medical reform. In my address to the profession (see *Lancet*, 1841, vol. xli., p. 153), I again adverted to the subject in the following terms:—"Every sincere well-wisher to medical reform must now be satisfied that there is not the slightest probability of a redress of our grievances, until we can acquire some power and influence in that House, from whence our measures have been so contumaciously ejected. It is to endeavour to persuade you to take steps for the advancement of this grand, this all-important object, that I once more address you. We may be assured, that without our own representatives in the Commons House of Parliament, no substantial good will be effected. Would it not be well for us to follow the example set us by the other professions? The interests of the church, and of the army, and of the navy, are fully represented. Even the mercantile and trading interests have their advocates and supporters; and what but our own supineness prevents us from having ours? I repeat, gentlemen, that if you desire to maintain that rank and station to which you are entitled, physicians, surgeons, and general practitioners, throughout the kingdom, must unite, for the purpose of returning a certain number of members to the House of Commons, pledged to support, watch over, and protect our interests. Had we been thus supported, the late administration would not have dared to disregard our petitions for the redress of our manifold grievances, and our endeavours to procure a wise and efficient measure of medical reform."

Again, in the DUBLIN MEDICAL PRESS, vol. v., p. 11, 1841, I wrote:—"But some may inquire, how is this vast power

to be achieved? Again I say, by union; by an union of the whole profession. Let it be borne in mind, that upon a very moderate computation, we are 20,000 strong; and that under the present reform bill, there are but few of us who do not possess a vote, which, by a little management, may be doubled, or even quadrupled; and our interest with our friends and connexions must be very small indeed, if we cannot each of us influence three or four votes more. Thus, were we but once fairly and duly organized, we might command at least 160,000 votes. Let this power be concentrated, and it will be irresistible. We have hitherto allowed ourselves to be driven like horses, and beaten like asses, because, like them, we have been ignorant of our united strength."

But I hear some exclaim, "Funds, funds! what are we to do for funds?" Let every medical man throw his receipts of one odd day, or upon emergency, of the five odd days of every year, into one common treasury, and an ample provision will be made for every political purpose. With such a revenue as this would produce, we might return ten or a dozen members of our own—good men and true, staunch to our interests; and have also ample means left to oppose all enemies of our profession.

If we would succeed in securing such a representation in the House of Commons, as would really be useful to us, we must adopt some bold and broad measure, such as I have now recommended; in other words, instead of calling upon Hercules to help us, we must put our own shoulders to the wheel, and help ourselves.

#### DOINGS AT THE SOUTH UNION WORKHOUSE.

THOUGH we have not yet noticed these proceedings, we have not been inattentive to what has been going on. It appears that a very small knot of the Guardians of this Union recently took it on themselves to appoint a temporary Physician to the Workhouse. As no public notice had been given of this appointment being about to take place, the Commissioners very properly annulled it; and the day of election is now fixed for the 10th of March. This, however, would be but a slight irregularity in itself; but are we credibly informed that the gentleman who was thus irregularly appointed is not qualified according to the rules laid down by the Commissioners? Should this be the case, we must protest against his reappointment. The situation of temporary Physician to a Workhouse is one of too much moment to be committed to the charge of an unqualified man, and we trust that the Commissioners will at once use the powers they possess to prevent any irregularity of the kind. We may return to this subject again.

#### GOVT BOARD OF GUARDIANS.

Mr. Rosengrave, on rising to move the reduction of some of the officers salaries, said, I feel much relieved from any anxiety I might otherwise labour under in proposing a reduction of salaries, by seeing assembled at this board the wealth, intelligence, and respectability of this union—men who, if I were inclined to do wrong, would not tolerate it; but who will give me now, as they have done on former occasions, their unanimous support while I propose that, and that only, which reason dictates, justice approves, and common sense sanctions. A man may spend many anxious days and restless nights, in wet and cold attend fairs and markets, and at the end of the year, after paying his rent and taxes, allowing for wear and tear on his farm, five per cent. for his capital engaged, he may not have £80 profit, while a workhouse officer, who has no capital engaged, no anxiety of mind, ought to be well satisfied with an equal sum. The first salary which he proposed to reduce was that of the medical officer, from £75 per annum to £50.

Mr. H. Lahiff was of opinion that Dr. Nolan should be allowed £50 for the parent house, £50 for the fever hospital, and £50 for the dispensary, and also, in addition, that Dr. Nolan be called on to compound his own medicines.

Mr. Rosengrave would assent to this arrangement in the event of the medical officer being satisfied to agree to it.

The board concurred in the proposition of Mr. Lahiff.

Mr. Rosengrave then said he had to propose the reduction of the apothecary's salary from £42 to £30; that is, in the event of Dr. Nolan refusing to accept the compounding.

Mr. Alexander opposed this, as well as all the reductions.

He conceived the salaries to be low enough already, as the labours of the several officers were great and important; he expressed a hope that the commissioners would not sanction it.

Mr. Harty said that the salary of the apothecary should not be reduced; he considered two medical officers necessary in every public institution.

Dr. Nolan sent in a strong protest against the reduction of his salary, grounded on the informality of the notice of motion and the disqualification of the mover, Mr. Tobias Rosengrave, from exercising any of the functions of a guardian under the 1 & 2 Vict., cap. 56, sec. 101. He then proceeded to enter minutely into several arguments against the proposed reduction, and, amongst others, stated that whilst the last rate, struck for the requirements of the union, averages 4s. 2d. in the pound, the present salaries of the officers, including those under the Medical Charities Act, amount only to 43d. in the pound, and finally concluded an able and comprehensive statement by expressing a hope that, as old and efficient officers were rewarded and promoted in other branches of the public service, they might not at least be reduced or curtailed in that of the poor-law commission.

The medical officer having been called in by the board, was asked his opinion as to the reduction of his salary and the compounding of medicines, when he protested against the reduction of his salary, and stated that he would not undertake the compounding department under any consideration. The board then adjourned.—*Clare Journal*.

This Mr. ROSENGRAVE is obviously an orator and a patriot, but still, as regards Medical Charities, evidently convinced that charity should begin at home, and that the Poorhouse Doctor's salary should be reduced to raise the return for the Ratepayer's capital. That's candid at all events, but what will the Commissioners say to it? We have reason for believing that, with perhaps one exception of peculiar nature, they have in a score or so of cases refused to sanction such reductions, while in many they have advised an increase. Dr. NOLAN is entitled to thanks for his firmness in defence of his rights. If others acted with equal decision, we should have less of such doings.

#### CLUBBING FOR MEDICAL ATTENDANCE.

I OBSERVE that you have been addressed by a gentleman complaining of the injurious operation of the free dispensary system; I have a complaint, too, that I should like to bring under your notice—it is that of the cheap club system, of which I must confess myself to have been a recent victim. I was induced, after long persuasion, to accept a club, whose members resided in different parts of the metropolis, at half-a-crown a head. When I had undertaken the duty, I found that for this paltry sum I had to go to Lambeth, and Camberwell, and the City Road; all these places sometimes in one day, to visit members suffering under diseases of every degree of severity. I found that the half-crown a year would be soon expended in additional cab hire, and that I was let in for an indefinite amount of gratuitous service. After keeping the club nine months, I resigned, an immense loser by the contract, but when I wanted my small pittance, I was informed that the club had resigned too—in fact, had dissolved; that somehow the money in the strong box had been divided among deserving objects, *e.g.*, treasurers, secretaries, auditors, &c., and that there was nothing left for the doctor. I then sent in bills to the individual members, but they refuse to pay. What am I to do? Submit to be robbed, or take legal proceedings, and in that case against whom?—*Letter in Medical Circular*.

We know not to what extent this method of providing medical relief for persons of limited means prevails in Ireland, but we know enough to satisfy us that it is very imperfectly worked; principally owing, we believe, to the ruinous competition which prevails amongst the members of our body. We are convinced that the operatives in every branch of business understand their interests sufficiently to perceive that valuable medical services cannot be obtained without adequate payment; they are also naturally inimical to all underselling transactions in their own "bodies," and must therefore feel that Dutch auctions of their club appointments are discreditable.

## POOR-LAW PAYMENT IN ENGLAND.

A SHORT time since, I inserted an advertisement in your columns for a situation as medical assistant; and among the various replies I received one from the guardians of the Cleobury-Mortimer Union offering a salary of £40 per annum for an assistant to dispense and vaccinate, &c. Of course, for such a sum I supposed my board, residence, &c., was found, but wrote, however, to satisfy myself fully on the subject, and received an answer that that, and that only, was the remuneration offered. Supposing I was able (which I very much doubt) to obtain board, residence, and every accommodation at £30 per annum, I should have just £10 for my services, besides incurring the expense of going to a place so far distant as Cleobury-Mortimer, which would be little short of £2. And this is the remuneration the board of guardians think sufficient for gentlemen of a liberal education. I immediately declined the situation, and expressed my astonishment that the board of guardians could ever think of offering such a niggardly sum. I do not know whether they have been able to get any one to accept it, but this I know—that if medical assistants were but true to themselves, we should soon hear no more of such shameful offers. The board of guardians would be obliged to double the salary before they would get any one to fill the situation.—*Letter in Lancet.*

I observe, by a late number, the way in which my professional brethren of Tewkesbury are rewarded for their important services by the guardians of that union. I think much credit is to be attached to them for protesting against an arrangement which must be most noxious to the medical officer, in consequence of his being paid so badly already. It has long appeared to me that the medical officers of this country are most shamefully remunerated for their services. The question is—How is this to be remedied? The ratepayer complains of the oppressive tax he suffers from, and he receives nothing in return. This is true; but how are the medical officers of unions to be paid for their hard-earned services? It can never be remedied, in my opinion, unless government will sanction the payment of medical officers being made a charge upon the Consolidated Fund. It is not one set of medical men in this country that ought to complain, it is the whole body throughout the kingdom: it must be “a pull, a strong pull, and a pull altogether,” that must effect the change.—*Letter in Medical Circular.*

Government payment of Medical Officers would afford little relief unless altogether made from the Consolidated Fund. A vote in aid to increase salaries granted by the Guardians would be a vote to the Ratepayer, who would close on the grant, and put his tongue in his cheek at the Doctors.

## HOUSE OF COMMONS—FEB. 21.

## NAVAL ASSISTANT-SURGEONS.

Colonel BOLDERO reminded the committee that in 1850 he advocated the cause of the assistant-surgeons, and carried a resolution which declared that the accommodation provided for them was inadequate and insufficient for securing the full benefit of their professional services. He was anxious to know what were the views of the present Board of Admiralty? The Lords of the Admiralty issued a memorandum on the 17th of July, 1850, which was not calculated to give effect to the resolution of the House. The memorandum was, indeed, extremely offensive to that class of officers, and was considered an insult to the whole medical profession. According to that memorandum they were to be allowed cabins only when the space on board would admit of it. This last exception would leave the whole matter to the Board of Admiralty, and defeat the resolution which the House had passed in 1850. He had received returns from the Mediterranean station, and out of twelve assistant-surgeons who had passed through all the ranks of their profession only five had received cabins; and only two had those little advantages which were enjoyed by the other officers in the ward-room. The result of this was that the élite of the candidates at the London, Edinburgh, Glasgow, and other colleges shunned the navy. In the event of a sudden war, where would the government obtain assistant-surgeons when such was their treatment? How could government expect candidates for medical situations in the navy when for three years they must remain in the cockpit, where study was next to impossible? What was the effect

of such a system? Mr. Guthrie, in his lectures, said that medical officers could not be found qualified for the navy, and that the system adopted by the Admiralty, instead of raising the value of the service, deteriorated it by employing persons of an inferior description. Was it desirable that they should continue a system which disgusted young men, and deterred them from entering into the naval service? It was even more necessary that there should be well qualified surgeons in the navy than in the army. The sailors depended entirely upon the assistance of medical men, and, if those men were such surgeons as were employed in 1809, what confidence could the service have in them?

Admiral BERKELEY would ask the hon. and gallant officer how he would like, as the colonel of a regiment, to have the discipline of his regiment and the internal arrangements of his regiment regulated by a naval officer? That was really the question. Admiral Berkeley affirmed that very great improvements had taken place on board ship, and that great additional accommodation had been afforded to the medical officers attached to the naval service. The Board of Admiralty had done all that was possible to carry into effect the resolution of April, 1850, and he expressed his regret to find the hon. and gallant officer doing so much to create dissatisfaction in the navy by his efforts to place the assistant-surgeons above their superior officers—the mates. The fact was, that the assistant-surgeons were, on the whole, very well off; and so far from there being any want of candidates, no fewer than fifty-four had entered within the last few months.

Mr. HUME said, that the question was whether the navy ought not to obtain as able and efficient medical assistance as the army? He could see no reason why both officers and men in the navy should not receive the best medical talent that was to be had; which, however, was impossible so long as the assistant-surgeons were treated as at present.

Mr. OSBORNE said, that the resolution of April, 1850, to which the hon. and gallant officer had referred, was carried by surprise in a thin house of eighty-eight members. He contended that for many years past there had been no class of men whose comforts had been more attended to than those of the assistant-surgeons. In 1840 a commission, composed of the Duke of Wellington, the Duke of Richmond, Sir George Cockburn, &c., reported that there were practical difficulties in the way of allowing the assistant-surgeons in all cases to mess in the ward-room; but that this was less essential, as they had ascertained that the accommodation afforded them of late years was so improved as to render it unnecessary for them to make any recommendation in that respect. The hon. and gallant officer had characterized the memorandum of July, 1850, as an insult to the medical profession. The recommendation of that memorandum was, that the assistant-surgeons should be allowed cabins where space would admit of them. He (Mr. Osborne) could not see where there was any insult in that. He found, from a return furnished in May, 1851, that the recommendation of the board had been carried out in all cases, except where it had been found utterly impossible; and what more would the hon. and gallant officer have?

Colonel BOLDERO assured the hon. and gallant admiral (Berkeley) that nothing was further from his intention than to create dissatisfaction in the navy, and that he had taken up the question solely as a matter of public duty.

Captain SCOBELL was astonished how the Admiralty had found it practicable to find cabins for so many. Cabins were impediments to clearing for action. There were other classes—such as the mates, who would be our future admirals—struggling upwards, who had claims for cabins as well as the assistant-surgeons, who were, no doubt, a very respectable class of men: but it must be considered that a ship was like that House—if all were to have seats, there would be no room for them.

## MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

DR. J. F. DUNCAN, Treasurer, begs to acknowledge with thanks the receipt of the following subscriptions since last report:—

Surgeon Colles, per Mr. Black	...	£1 0 0
Dr. Kirby	...	1 1 0
Surgeon Wilmot	...	1 0 0
Dr. Butler, Sackville-street	...	1 1 0
Dr. Corbett, Cork	...	1 1 0

19, Gardiner's-place, March 7, 1853.

On April 1st, will be published, Part I., of the  
**"GLASGOW MEDICAL JOURNAL."**  
 (To be continued Quarterly.)

Subscription twelve shillings per annum, payable in advance; for which sum it will be sent *post free* to all parts of the united kingdom, and to the greater number of the British Colonies.

Prospectuses, *post free*, on application to

RICHARD GRIFFIN and Co., Glasgow.

#### UNIVERSITY OF LONDON.

NOTICE is hereby given, that on Wednesday, 6th of April next, the Senate will proceed to elect Examiners in the following departments:—

Examinerships.	ARTS.	Salaries.	Present Examiners.
One in <i>Classics</i> .....	150l.		T. B. Burcham, Esq., M. A.
Two in <i>Mathematics and Natural Philosophy</i> ...	150l.		{ Rev. Prof. Heaviside, M. A. G. B. Jerrard Esq., B. A.
Two in <i>Logic, Moral and Intellectual Philosophy</i>	50l.		{ Rev. H. Alford, M. A. T. B. Burcham, Esq. M. A.
One in <i>Chemistry</i> .....	50l.		Prof. Graham, M. A., F. R. S.
One in the <i>French Language</i> .....	40l.		{ C. J. Delille, Esq.
One in the <i>German Language</i> .....	40l.		{ Rev. A. Walbaum.
Two in the <i>Hebrew Text of the Old Testament, the Greek Text of the New Testament, and Scripture History</i> .....	50l.		{ Rev. W. Drake, M. A. Rev. Prof. Gotch, M. A.
MEDICINE.			
One in the <i>Practice of Medicine</i> .....	150l.		{ Alexander Tweedie, Esq., M. D., F. R. S.
One in <i>Surgery</i> .....	150l.		Jos. Hodgson, Esq. F. R. S.
One in <i>Anatomy and Physiology</i> .....	150l.		{ Professor Sharpey, M. D., F. R. S.
One in <i>Physiology and Comparative Anatomy</i>	100l.		{ Professor Carpenter, M. D. F. R. S.
One in <i>Midwifery and the Diseases of Women and Infants</i> .....	100l.		{ Edward Rigby, Esq., M. D.
One in <i>Materia Medica and Pharmacy</i> .....	100l.		{ Vacant.

The present Examiners are eligible, and intend to offer themselves, for reëlection.

Candidates must announce their names to the Registrar on or before the 30th of March.

By order of the Senate,

R. W. ROTHMAN, Registrar.

Somerset House, March 2, 1853.

#### THE MIDLAND RETREAT,

(NEAR MARYBOROUGH, ON THE GREAT SOUTHERN AND WESTERN RAILWAY.)

For the reception and treatment of the INSANE, and of persons suffering from a disturbed state of the Nervous System.

Under the direction of Dr. JACOB,

Physician to the Maryborough District Lunatic Asylum (containing 200 patients), Surgeon to the Queen's County Infirmary, &c.

THIS ESTABLISHMENT, which has recently been considerably enlarged on the most improved principles, consists of two separate and commodious residences—Anne Brook for the reception of Ladies—Woodville for Gentlemen,—each situated on extensive and highly ornamented grounds, with large well-enclosed gardens. Neither house presents any of the usual characters of a lunatic asylum, as they are handsome, well-furnished country residences, where the patients enjoy all the comforts and indulgences of a private house, without being exposed to what might distress the feelings by giving rise to the idea of confinement. Arrangements have been made by which the inmates have been secured the benefit of the professional services of the parochial clergy. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients. Evidence of the most conclusive character as to the efficient and superior manner in which the establishments are conducted can be presented on reference to the Proprietor. There is daily communication, by means of public conveyances, with Dublin, Cork, Limerick, Waterford, Clonmel, Kilkenny, Carlow, Enniscorthy, Galway, Athlone, &c., and intermediate towns.

#### THE PHARMACEUTICAL JOURNAL, MARCH 1,

CONTAINING THE TRANSACTIONS OF THE PHARMACEUTICAL SOCIETY.

CONTENTS: Memoir of the Life of the late Jonathan Pereira, M.D.—Percira Memorial Fund—The Admission of Members into the Pharmaceutical Society—Supply of Medicines to Emigrant Vessels—Cortex Alstonie Scholaris—Extract of Colocynth—Cautehouse and Gutta Percha—Composition of Instantaneous Light Matches—Manufacture of Nitric Acid—Wood Wool—Manufacture of Gas—Tests for the Cinchona Alkaloids—The Use of Coffee Leaves in Sumatra—The Dose of Tincture of Aconite—Drop-Bottle (*with Cut*)—Soap—Indigo—Cod-Liver Oil—Adulteration of Arnica Leaves and Guaiacum Wood—Manufacture of Sulphuric Acid—Chemical Society, &c. &c. Price 1s.

London: John Churchill, Princes-street, Leicester-square; MacLachlan and Stewart, Edinburgh; and Fannin and Co., Dublin.

\* \* Volume XI. may be had in boards, as well as the preceding volumes, price 12s. 6d. each.

G. OLDHAM and Co., Pharmaceutical Chemists and Apothecaries, 107, Grafton-street, and 64, Dame-street, Dublin (Agents for the sale of Mr. Coxeter's Surgical Instruments), invite the attention of the Medical Profession to their present Stock of Instruments, all of which are manufactured on the most approved principles.

Superior Dissecting Instruments well worth the inspection of the Student.

G. O. AND CO. ARE ALSO SOLE AGENTS FOR THE SALE OF H. NEWSON'S PATENT WIRE TRUSS, WHICH IS NOW RECOMMENDED BY THE FIRST MEDICAL AUTHORITIES.

#### THE COMPOUNDING DEPARTMENTS AT G. O. AND CO.'S MEDICAL HALLS

are separated from the Retail, to prevent interruption and irregularity, and obtain the especial care of the Proprietors. Anxious to give satisfaction to the Medical Profession, G. O. and Co. commenced dispensing medicine with the resolution to devote to it their unremitting personal attention; to employ none but experienced Assistants; to render prices as moderate as it is possible for any house that confines itself to the best articles; and to supply, either in the simple state or in combination, the most effective medicines that can be procured or prepared, and on which the Practitioner may rely.

BLEEDING, CUPPING, THE APPLICATION OF LEECHES, &c.

G. O. and Co. continue to be supplied with the FOREIGN MINERAL WATERS FRESH from their various SPRINGS.

Medicines delivered by Van in all parts of the city and suburbs, and along the line of the Kingstown Railway, at any hour, free of charge.

#### TO SURGEONS, DISPENSING CHEMISTS, ETC.

SULPHATE OF QUININE, pure CRYSTALLIZED, prepared by EDWARD HERRING, of the late Firm of HERRING, Brothers, for the Use of Hospitals, Dispensaries, &c.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its PURITY AND GREAT REDUCTION IN PRICE are now attracting the attention of Medical Practitioners and the Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, capped, with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London and the United Kingdom, and in quantities of not less than 100 ounces, of

JACOB HULLE, Jun., Proprietor,

Chemical Works, Trinity-street, Southwark, London.

Printed by Thomas Deey, at 15, Molesworth-street, and published there every Wednesday morning, for the Proprietor, ARTHUR JACOB, M.D., 23, Ely-place, in the City of Dublin. London: John Churchill, 46, Princes-street, Soho.

Wednesday, March 9, 1853.
